Hydrastis canadensis, Gray, *Manual of Bot.*, 14; figured in Griffith's *Med. Bot.*, 82.—This is a small, herbaceous, perennial plant, with a thick, fleshy, yellow rhizome, from which numerous long roots arise, and an erect, simple, pubescent stem, from six inches to a foot in height. There are usually but two leaves, which are unequal, one sessile at the top of the stem, the other attached to the stem a short distance below by a thick roundish footstalk, causing the stem to appear as if bifurcate near the summit. The leaves are pubescent, roundish-cordate, with from three to seven, but generally five, lobes, which are pointed and unequally serrate. A solitary flower stands upon a peduncle rising from the basis of the upper

leaf. It is whitish, rose-colored, or purplish, without corolla, but with a colored calyx, the sepals of which closely resemble petals, and are very caducous, falling very soon after the flower has expanded. The fruit is a globose, compound, red or purple berry, half an inch or more in diameter, composed of many fleshy carpels, each tipped with a short curved beak, and containing one or rarely two seeds. The plant grows in moist, rich woodlands in most parts of the United States, and at one time abundantly in the North and West. The fruit bears a close resemblance to the raspberry, but is not edible. The root is the part used. The Indians employed it for staining and dyeing yellow, and it is said to impart a rich and permanent yellow, and with indigo a fine green, to wool, silk, and cotton. There is but one other species of *Hydrastis* known,—viz., *H. jezoensis*, Sieb. et Zucc., which is found in Northern Japan. For morphology of *hydrastis* see *Chem. Zeit.*, 1894, 134, and for botanical description by J. U. Lloyd, see *West. Drug.*, 1897, 59.

Properties.—The fresh root is juicy, and loses much of its weight in drying. The dried caudex is officially described as a "rhizome of oblique growth, subcylindrical, straight or somewhat tortuous, 2 to 5 Cm. long, and 3 to 6 Mm. in diameter, with short stem remnants, or stem scars, and slightly annulate; externally brownish-gray to yellowish-brown; fracture short, waxy, deep yellow; bark about 0.5 Mm. thick, wood wedges bright yellow, pith large, light yellow; the roots thin, brittle, with a thick yellow bark and a somewhat quadrangular wood; odor distinct; taste bitter. Sections of *Hydrastis* treated with sulphuric acid show under the microscope the separation of the alkaloids in prismatic, tabular, and acicular crystals." U. S. The rhizome breaks with a clean resinous fracture, leaving a smooth brownish-yellow or greenish-yellow surface, exhibiting a ring of bright yellow with somewhat distant narrow wood-bundles. Many of the detached rootlets are mixed with the rhizomes in mass. The color of the rhizome, though yellow in the recent root, becomes a dark yellowish brown by age; that of the rootlets and the interior of the root is yellow, and that of the powder still more so. The odor is sweetish, and somewhat narcotic, the taste bitter and peculiar. The medicine imparts its virtues and coloring matters to water and alcohol. Examined by Alfred B. Durand of Philadelphia, it was found to contain albumen, starch, fatty matter, resin, yellow coloring matter, sugar, lignin, and various salts. He also discovered a peculiar nitrogenous, crystallizable substance, for which he proposed the name of *hydrastine*. (*A. J. P.*, 1851, p. 112.) It has also been determined that the root contains another alkaloid, to which it owes its yellow color, and which is probably identical with the yellow coloring matter of Durand. F. Mahla first ascertained that this

new alkaloid of hydrastis is berberine.¹ (*Am. J. S.*, Jan. 1862, p. 43.) It exists in large proportion in hydrastis, constituting, according

¹ *Berberine*.—This alkaloid appears to have been first discovered, in 1826, in a species of *Xanthoxylum*, by Chevallier and Pelletan, who, from its color and taste, named it *xanthopicroie*; Buchner and Herberger, in 1835, found it in *Berberis vulgaris*, and named it berberine; but none of these chemists were aware of its alkaline properties. Indeed, the substance obtained by them at a native sale of the proper alkaloid, which was not, therefore, procured in a pure state. Subsequently Fleitmann demonstrated its basic character, and published an account of several of its salts. It is not confined to the barberry, but has been found, by several chemists, in several other plants, particularly those products combining bitterness and a yellow color, as in *Cocculus palmatus*, *Hydrastis canadensis*, *Xanthorrhiza apifolia*, *Coptis teeta*, *Fagara Clava-Herculis*, *Coscinium fenestratum*, and others belonging to the natural families of Berberidaceæ, Menispermaceæ, and Ranunculaceæ. Indeed, few if any of the known alkaloids are so widely diffused as this appears to be in the vegetable kingdom. A list of the plants from which it has been obtained is contained in *A. J. P.*, Sept. 1863, p. 456.

Berberine may be obtained most readily from its sulphate. Procter has given the following process for preparing it, based upon a suggestion of Merrill, of Cincinnati. The coarsely powdered root is to be exhausted by repeated decoction with boiling water, and the mixed liquids, after filtration, are to be evaporated to a soft extract. This is to be digested several times with stronger alcohol, in the proportion of a pint to half a pound of the root, until exhausted, one-fourth of its bulk of water is to be added to the tincture, and five-sixths of the alcohol to be distilled off. To the residue, while still hot, sulphuric acid is to be added in excess, and the liquid allowed to cool. The berberine sulphate is deposited in crystals, and, having been purified by recrystallization, is to be decomposed by the addition, in excess, to its solution in boiling water, of freshly precipitated lead monoxide, the solution being kept hot until the decomposition is completed. This may be known by the absence of a precipitate when lead acetate is added to a drop of the clear liquid. The liquid is then to be filtered, and set aside to crystallize. The berberine sulphate may be decomposed by treatment with barium hydroxide, removing excess of barium by carbon dioxide, concentrating and crystallizing. It may also be made by precipitating a concentrated aqueous extract of any drug containing berberine by excess of sulphuric acid. Thus obtained, berberine is in the form of a yellow powder, which, under the microscope, appears to consist of groups of minute, acicular crystals. It has a bitter taste, is soluble in about 100 parts of cold water, still less soluble in cold alcohol, freely soluble in both these liquids when hot, and insoluble in ether. It forms salts of difficult solubility with hydrochloric and sulphuric acids, and is distinguished by being copiously precipitated by the former acid from its cold water solution in the form of crystals of the hydrochloride. It is freely dissolved by acetic acid, which forms with it a readily soluble salt. (*A. J. P.*, Jan. 1864, 10.) Its formula is, on the authority of Perrins, $C_{20}H_{17}NO_4$. (*P. J.*, April, 1863, 44.) Hlasiwetz (*Ann. Ch. Ph.*, 115, 45) also confirms this formula, which may therefore be assumed as correct. Gaze's method consists of the preparation of an insoluble compound of berberine with acetone, and then liberating the berberine by boiling the compound with a mixture of alcohol and chloroform for 12 hours under a reflux condenser. This method has been criticized by Gordin, who found that Gaze's product was not pure berberine. (*Proc. A. Ph. A.*, 1901, 228.) *Berberine hydrochloride*, which is the salt that has attracted most notice, may be readily obtained by using hydrochloric instead of sulphuric acid in the above process, and purifying the precipitate by solution in hot alcohol, and subsequent refrigeration. It is in fine acicular crystals of a bright yellow color and intensely bitter taste, very slightly soluble in cold water, to which, however, it imparts a deep yellow color, slightly soluble in cold alcohol, but dissolved in large proportion by both liquids when hot. By concentrated nitric acid both this salt and its base are decomposed, with the production of a dark red color and the escape of nitrous fumes. A process for berberine hypophosphite, by J. U. Lloyd, may be found in

to Perrins, nearly 4 per cent. There can be no doubt that this medicine owes much of its virtue to berberine. For a valuable paper by J. U. Lloyd on the preparation of salts of berberine, see *A. J. P.*, 1879, p. 11. Lerre's process based on Lloyd's for preparing hydrastine and berberine is as follows:

First Process.—Two thousand pounds of golden seal in No. 40 powder is exhausted with 80 per cent. boiling alcohol in a hot extraction apparatus, careful recovery leaving a dark syrup containing the total active ingredients. This is withdrawn and immediately added to five times its volume of warm water, and the whole allowed to stand 24 hours, by which time the resinoids have separated. The bright chocolate liquid is now acidified with sulphuric or hydrochloric acid in excess, and allowed to stand 24 hours, when most of the liquor may be decanted; the residual berberine salt is easily strained off, washed, and is then ready for purification. To the combined liquors an excess of alkali is added which throws out the impure hydrastine, which after washing and drying is ready for purification. All liquors are rejected. The berberine salts are purified by repeated crystallizations from boiling water, and finally in alcohol. Fair samples of drug yield about 3½ per cent. The crude hydrastine is dissolved in boiling alcohol or chloroform, filtered and recrystallized. The yield is about 1½ per cent.

Second Process.—The above quantity of crude drug may be macerated with a 2 per cent. solution of acetic acid, and this at first sight would seem the better process; practice, however, leads to an opposite deduction, as the quantities of liquid to be handled are greater and the troubles in purifying multiplied. (*D. C.*, 1897, 34.) A substance obtained by the precipitation of an infusion of the root by hydrochloric acid has been for some time known and used by the "Eclectics," under the name of *hydrastin*; it consists of a small proportion of hydrastine, with berberine and resin (*A. J. P.*, 1876, p. 386), and the reader must be cautious not to confound this substance with the alkaloid to which the name properly belongs.² Perrins obtained 1.5 per cent. of it

A. J. P., July, 1877. Parsons (*N. E.*, 1879, 109) analyzed berberine phosphate, and believes the formula to be $C_{20}H_{17}NO_4 \cdot 2H_3PO_4$.

According to the studies of Falck and Guenete, berberine causes in dogs and rabbits restlessness, convulsive tremblings, hurried respiration, and diarrhoea, followed, if the dose has been large enough, by decrease of the breathing rate, wide-spread paralysis, dyspnoea, convulsions, and death. In man as yet no serious symptoms have been recorded as produced by it. Buchner is stated to have taken nearly twenty grains without causing anything more serious than a loose stool. It has been employed in internal medicine as a simple bitter, in doses of from two to five grains (0.13 to 0.32 Gm.).

² Wilhelm (*P. J.*, 1883, 325) furnishes a process for obtaining the alkaloids from hydrastis as follows. The extract obtained by treating the coarsely powdered root with water acidified with acetic acid at 100° F. is evaporated to a syrup and excess of diluted sulphuric acid added, when berberine sulphate separates. The filtrate neutralized with ammonia water gives a precipitate containing much hydrastine; this is separated, and on adding ammonia

from the root, and, having given five grains of it to a rabbit without any other effect than a slight uneasiness which soon ceased, concluded justly that it was not poisonous.

Canadine ($C_{20}H_{21}NO_4$) was extracted by E. Schmidt; it occurs in the form of brilliant, small, white nodules, melting at 134° C. (273.2° F.). When canadine is dissolved in alcohol and treated with iodine, berberine hydriodide (which is yellow in color) is formed. Canadine was believed to be identical with dihydromethylberberine (*Ph. Post*, 1892, 230), and the formula $C_{21}H_{21}NO_4$ was given to it. E. Schmidt, however (*A. Pharm.*, 1894, 136 to 154), has found that its true formula is $C_{20}H_{21}NO_4$, and, owing to the fact that iodine forms with it berberine hydriodide, he believes that canadine is a tetrahydroberberine. Schmidt also obtained, as an additional product of the iodine reaction, the hydriodide of another base, which he believes is intermediate between berberine and canadine. For a process for isolating canadine, see *Proc. A. Ph. A.*, 1894, 1103. The alkaloid discovered by A. K. Hale, and obtained later by Burt and by Lerehen, and which was named *xanthopuccine*, is now considered to be identical with canadine. For processes for making hydrastine and berberine, see *D. C.*, 1897, 34. It is probable, from the odor of hydrastis, that besides the two alkaloids here mentioned it contains also an active volatile principle, but this has not yet been isolated.

Assay.—"Hydrastis, in No. 60 powder, fifteen grammes; Ether, Ammonia Water, Distilled Water, Normal Sulphuric Acid V.S., each, a sufficient quantity. Introduce the Hydrastis into an Erlenmeyer flask of 250 Cc. capacity, add 150 Cc. of ether, shake the flask occasionally during ten minutes, and add 5 Cc. of ammonia water, again shaking the flask at intervals during half an hour. Then add 15 Cc. of distilled water to the mixture in the flask and shake it until the drug collects in masses, and at once pour off, into a measuring cylinder, 100 Cc. of the supernatant ether-solution and transfer it to a separator. Add 15 Cc. of normal sulphuric acid V.S. to the separator, and shake it moderately during one minute. Allow the liquids to separate, and draw off the lower acid liquid into a second separator. Again

water in excess to the filtrate a further precipitate is produced, which contains *canadine*. Both precipitates, boiled with ethyl acetate, give solutions which on cooling deposit hydrastine in large crystals, somewhat colored, but rendered pure by recrystallization. The crystals from the second ammonia precipitate are much purer than those from the first; by slow evaporation of the ethyl acetate solution they can be obtained as large as walnuts.

Hydroberberine (Canadine), whose molecule contains four atoms of hydrogen more than the molecule of berberine, is said by Marford to differ from berberine physiologically; it produces in moderate dose an increase in the blood pressure by stimulating the vasomotor centre in the medulla. *Opianic*, *hydrastinic*, and *berberinic acids* are said by the same authority to be almost inert physiologically, except that they are feebly antiseptic. (*T. G.*, 1890.)

For a physiological study of the methylamine derivatives of hydrastine (*hydrastine methylamine*), see *V. A. P. A.*, cxlii., 1895.

shake out the ether-solution with 5 Cc. of normal sulphuric acid V.S. and 5 Cc. of distilled water, and shake the separator for one minute. After the liquids have separated, draw off the acid solution as before into the second separator. Repeat the same process with 5 Cc. of distilled water, drawing this also into the second separator. Introduce a small piece of red litmus paper into the second separator, add enough ammonia water to render the liquid alkaline, and then 25 Cc. of ether, and shake the separator moderately during one minute, and when the liquids have separated, draw off the lower alkaline liquid into another separator, and the ether-solution into a tared beaker. Again shake out the alkaline liquid, using 20 Cc. of ether, shake the separator for one minute, and when the liquids have separated, draw off the alkaline liquid into the other separator, and the ether-solution into the tared beaker. Finally, again shake out the alkaline liquid, using 15 Cc. of ether, proceeding as before, and adding the ether-solution to the liquid in the tared beaker. Evaporate the ether carefully with the aid of a water-bath, and dry the alkaloidal residue in the beaker to a constant weight at 100° C. (212° F.). The weight found, multiplied by 10, will give the percentage of hydrastine in the Hydrastis." *U. S.*

Uses.—As a local remedy hydrastis has a very decided effect upon the mucous membrane. It has been used with asserted remarkable results in chronic *gastro-intestinal catarrhs*, especially those due to alcoholic excess, and as the commercial hydrastine is one of the drugs that was found in the experiments of Rutherford to notably increase the biliary secretion in the lower animals, it is probable that in gastric diseases attended by *hepatic congestion* and lack of functional activity it exerts an almost specific influence. It has been strongly recommended in *dyspepsia* and the *vomiting of pregnancy*. It is much used by specialists as a local remedy in the treatment of *otorrhœa*, *nasal*, *vaginal*, and other *catarrhs*. In the second stage of *gonorrhœa*, as an addition to injection mixtures, it may be of great service. In chronic or subacute *inflammations* of the *colon* and *rectum* injections of hydrastis are often of great service, and it has been used in *hemorrhoids* with asserted excellent results.

The strength of the local application of hydrastis to be used in various diseases of the mucous membrane varies from half a fluidrachm to two drachms of the fluidextract to one ounce of diluent. In *gonorrhœa* from five to ten grains (0.32 to 0.65 Gm.) of commercial hydrastine, or forty to eighty minims (2.5 to 5 Cc.) of the fluidextract, may be used to the fluidounce. In *hemorrhoids* from two to four drachms to the fluidounce may be used. The glycerite¹ is not so useful a local preparation

¹ *Liquor Hydrastine.*—Under the names of *Liquid Hydrastis*, *Fluid Hydrastis*, *Colorless Hydrastis*, etc.,

as the fluidextract diluted with water, a deposit of the insoluble resinous substance upon the mucous membrane and its constant prolonged influence being important.

The general action of hydrastis upon the system is probably chiefly due to its hydrastine (see p. 640).

It is essential to recognize the differences, medicinally, between the preparations of hydrastis. The so-called *hydrastin* of commerce is really an impure body, containing berberine, canadine, hydrastine, and probably some resin. It is this mixture which Rutherford found to have a pronounced influence upon the biliary secretion in the lower animals. Whether this action is or is not dependent upon the presence of berberine or other impurities is as yet uncertain. The practical deduction is, however, that when hydrastis is to be used in chronic gastrointestinal catarrh, or as a local application to the mucous membrane, it is better to use hydrastin or the fluidextract rather than the pure alkaloid. The dose of this hydrastin is from five to ten grains (0.32 to 0.65 Gm.).

There is some reason for believing that *berberine* has a special action upon the gastrointestinal tract. Marfori has, however, found that even in large therapeutic dose it is without perceptible influence upon the circulation or the nervous system. When, therefore, a preparation of hydrastis is to be used for effects other than a local action on the gastro-intestinal or other mucous membrane, a salt of the pure alkaloid hydrastine should be used. There is abundant clinical testimony to the great value of hydrastine in the treatment of *uterine hemorrhages*, whether occurring in the non-parturient or in the parturient woman.

Dose, of hydrastis, fifteen to thirty grains (1 to 2 Gm.).

HYOSCINÆ HYDROBROMIDUM.

U. S., Br.

HYOSCINE HYDROBROMIDE [*Hyoscine Hydrobromas*, Pharm. 1890, *Hyoscine Hydrobromate*]

(hŷ-ŋs-cŷnæ hŷ-drŋ-brŏ'mj-dŭm)

"The hydrobromide [$\text{HBr} \cdot \text{C}_{17}\text{H}_{21}\text{NO}_4 + 3\text{H}_2\text{O}$] of an alkaloid, chemically identical with scopalamine, obtained from *Hyoscyamus* and

other plants of the *Solanaceæ*. It should be kept in well-stoppered, amber-colored vials." *U. S.* "The hydrobromide, $\text{C}_{17}\text{H}_{21}\text{NO}_4 \cdot \text{HBr}$, $3\text{H}_2\text{O}$, of an alkaloid contained in *Hyoscyamus* Leaves, different species of *Scopola*, and possibly other solanaceous plants." Br.

Hyoscinum Hydrobromicum: Hydrobromate of Hyoscine. *Scopolamine Hydrobromide*: Bromhydrate d'Hyoscine, Fr.; *Scopolaminum hydrobromicum*, P. G.; *Scopolaminhydrobromid*, *Hyoscinhydrobromid*, *Bromwasserstoffsaures Hyoscin*, G.

This salt was introduced for the first time in the *U. S. P.* 1890. *Hyoscine*, $\text{C}_{17}\text{H}_{21}\text{NO}_4$, is found in the leaves and seeds of *Hyoscyamus niger*, *Duboisia myropoides*, *Scopola japonica*, *Atropa Belladonna* and other solanaceous plants. Pure hyoscine forms a syrupy liquid. The best salt for practical use is the hydrobromide, which is in "colorless, transparent, rhombic crystals, sometimes of large size, odorless, having an acrid, slightly bitter taste; slightly efflorescent. Soluble in 1.5 parts of water, 16 parts of alcohol, and in 750 parts of chloroform at 25° C. (77° F.); soluble in 1.33 parts of alcohol at 60° C. (140° F.); insoluble in ether. Its aqueous solution shows a slightly acid reaction to blue litmus paper. Hyoscine Hydrobromide, when heated, softens at about 100° C. (212° F.); it first melts and then loses its water of crystallization at 110° C. (230° F.). If dried over sulphuric acid until deprived of its water of crystallization, it melts at 179.7° C. (355.5° F.). When ignited, it leaves no residue. Hyoscine chloraurate crystallizes in yellow prisms and melts at 197° C. (386.6° F.). Hyoscyamine chloraurate crystallizes in yellow leaflets and melts at 160° C. (320° F.). Atropine chloraurate crystallizes in dull yellow grains and melts at 136° C. (276.8° F.). If 2 Cc. of chloroform be shaken with 1 Cc. of solution of Hyoscine Hydrobromide (1 in 10), to which a few drops of chlorine water have been cautiously added, it should assume a brownish color. If 0.01 Gm. of the salt be added to 5 drops of nitric acid, and evaporated to dryness in a porcelain dish, the residue should yield a violet color upon the addition of alcoholic potassium hydroxide T.S. Silver nitrate T.S., when added to a solution of the salt, affords a yellowish-white precipitate insoluble in nitric acid, but the washed precipitate is soluble in an excess of ammonia water. Mercuric potassium iodide T.S., in aqueous solutions of the salt acidified with hydrochloric acid, yields a yellowish-white precipitate. Mercuric chloride T.S. and solution of phosphotungstic acid give a white precipitate when added to an aqueous solution of the salt. Pieric acid T.S. and platinic chloride T.S. yield yellow precipitates when added to a concentrated solution of the salt. Sulphuric acid should give no color when added to Hyoscine Hydrobromide (absence of *carbonizable impurities*); nor should any color be developed on the subsequent addition of a drop of nitric acid (absence of *morphine*)." *U. S.* "It

preparations of the alkaloids of hydrastis have been largely used. In some cases these solutions have been made directly from the drug by depriving a fluidextract of coloring matter (see *Glyceritum Hydrastis*), in others the alkaloid has been dissolved in a suitable liquid. Gust. Steinman (*A. J. P.*, 1887, 296) examined several samples and found hydrastine in each, combined with either sulphuric or hydrochloric acid, besides aluminum, potassium, boric acid, etc., in small proportion; by dissolving 20 grains of hydrastine sulphate or hydrochloride in a pint of a solution of glycerin and water (sp. gr. 1.15), a liquid is produced from which the asserted good results can be obtained.

has an acrid, slightly bitter taste, and is odorless. It is soluble in 1 part of cold water and in 13 parts of alcohol (90 per cent.), very slightly soluble in ether or chloroform. When heated to 212° F. (100° C.) it loses rather more than 12 per cent. of its weight and fuses to a viscid mass which becomes liquid at a temperature of 379.4° to 381.2° F. (193° to 194° C.). An aqueous solution yields a precipitate with test-solution of mercuric chloride, solution of iodine, or solution of potassium hydroxide, but not with solution of ammonia or solution of potassium bichromate. It forms with auric chloride a crystalline salt having a melting point of 388.4° F. (198° C.). It affords the reactions characteristic of hydrobromides. Its aqueous solution slightly reddens litmus. Heated to redness with access of air it leaves no residue." *Br.*

E. Schmidt (*Ap. Ztg.*, 1891, 522) believes that the hyosine hydrobromide of commerce is essentially hydrobromide of *scopolamine*, $C_{17}H_{21}NO_4$. This view has been confirmed by O. Hesse (*Ann. Ch. Ph.*, 1893, 304), and the British Pharmacopœia defines hyosine as an alkaloid contained in *hyoscyamus*, different species of *Scopola*, and possibly other solanaceous plants, while the German Pharmacopœia changed the title to "*Scopolaminum Hydrobromicum*." The U. S. Pharmacopœia (8th Rev.) introduced *Scopolaminæ Hydrobromidum* as a separate title, but referred to *Hyoscine Hydrobromidum* for the description and tests, declaring them to be identical substances. *Atroscine* was found by Hesse in variable amount in the hyosine hydrobromide of commerce. It is a mydriatic equal in power to atropine or scopolamine.

Uses.—Various observers have noted that the impure amorphous hyoscyamine is more powerful than the crystallized alkaloid. These observations, with the chemical fact that amorphous hyoscyamine is chiefly hyosine, in 1884 led H. C. Wood to make a careful physiological study of that alkaloid upon the lower animals and to apply it to clinical medicine. It was found that the pure hyosine produced in the frog, motor reflex paralysis, due to a depression of the spinal cord, and that in mammals it caused disturbance of respiration, loss of muscular power, pronounced tendency to stupor, and, finally, death by asphyxia. It exerts very little influence upon the circulation even when in toxic doses. It became evident that the drug was a depressant of the principal cerebral centres, of the respiratory centres, and also of the lower motor centres of the spinal cord. In man, the ingestion of hyosine in decided doses is followed in a very short time by dryness of the mouth, flushings of the face, great sleepiness, associated in some cases with delirious mutterings, and giddiness akin to that of alcoholic intoxication. The respirations are usually lessened in frequency, and the pulse rate is also somewhat diminished. Dilatation of the pupils is usually, but not invariably, produced. After

toxic doses these symptoms are intensified, while the frequent loss or impairment of the power of swallowing, and a peculiar hoarseness of the voice, with, in some cases, laryngeal dyspnoea, indicate that the muscles of the larynx, as well as those of the pharynx, have a special tendency to be paralyzed by the alkaloid; the respiration not only becomes slow and full, but sometimes takes on a distinctly Cheyne-Stokes character; the skin is not dry, as in atropine poisoning, but is frequently covered with sweat. No cases of fatal poisoning are on record. One-fourth of a grain (0.016 Gm.) of very impure hyosine produced in the case of Hutchinson profound muscular relaxation, with quiet coma lasting for eleven hours. In applying hyosine to the treatment of disease, H. C. Wood found that it is a valuable soporific, especially useful in those cases in which the wakefulness is complicated with or due to cerebral excitement. In *insomnia* produced by overwork, when the brain seems to lose the capability of ceasing its action, hyosine is of service; but it is especially valuable in actively delirious conditions, such as occur in *acute mania* or in exacerbations in the course of *chronic mania*. In those cases in which morphine increases the cerebral excitement hyosine usually acts most happily. According to the statements of Bruce and Tirard, it is an entirely safe remedy in cases of severe kidney disease when morphine is contra-indicated. H. C. Wood has found that it is an efficient remedy in the treatment of sexual excitement, such as *nymphomania*, *spermatorrhœa*, and allied affections, and that it will almost invariably control *excessive seminal emissions*. Hyosine rarely, if ever, produces much more serious after effects than a little dryness of the throat and headache, and does not disturb the alimentary canal. The reports of later clinicians indicate that excessive susceptibility to its influence is a not infrequent idiosyncrasy, and it is even affirmed that one two-hundredth of a grain has caused alarming symptoms. It is probable, however, that much larger doses were taken in these cases than is alleged. On account of its tendency to produce pharyngeal and laryngeal paralysis, it should not be employed in such diseases as scarlet fever or diphtheria when there is a tendency to throat difficulties. Being practically tasteless, hyosine is readily given in food or drink without the knowledge of the patient. It acts well when taken by the mouth, but is especially efficient and prompt when administered hypodermically, and never produces local irritation. The effects of a hypodermic dose are usually manifested inside of ten minutes, and persist for six or eight hours.

The dose by the mouth is from one one-hundred and twentieth to one-sixtieth of a grain (0.0005 to 0.001 Gm.); for hypodermic injections one one-hundred and fiftieth to one one-hundredth of a grain (0.0004 to 0.0006 Gm.). On account of the susceptibility of some persons to it, the commencing dose by the mouth

should not be over one one-hundred and twentieth of a grain (0.0005 Gm.), by injection one one-hundred and fiftieth of a grain (0.0004 Gm.); after cautious trial, doses larger than the maximum just given may be employed.

Dose, one one-hundred and fiftieth to one eightieth of a grain (0.0004 to 0.0008 Gm.).

HYOSCYAMINÆ HYDROBROMIDUM.

U. S.

HYOSCYAMINE HYDROBROMIDE [Hyoscyaminæ Hydrobromas, Pharm. 1890, Hyoscyamine Hydrobromate]

(hŷ-qs-cŷ-ā-mī'næ hŷ-drō-brō'mj-dūm)

$C_{17}H_{23}NO_3 \cdot HBr = 367.40$

"The hydrobromide [$HBr \cdot C_{17}H_{23}NO_3$] of an alkaloid obtained from hyoscyamus and other plants of the *Solanaceæ*. It should be kept in amber-colored, well-stoppered vials." U. S.

Hyoscyaminum Hydrobromicum: Bromhydrate d'Hyoscyamine, Fr.; Hyoscyaminhydrobromid, Bromwasserstoffsäures Hyoscyamin, G.

Preparation.—This salt may be made by dissolving 10 Gm. of hyoscyamine in 11 Gm. of hydrobromic acid (25 per cent.), evaporating and crystallizing.

Properties.—Hyoscyamine hydrobromide is officially described as in "white, prismatic crystals, or a yellowish, amorphous, resin-like mass, having, particularly when damp, a tobacco-like odor, and an acrid, nauseous, and bitter taste; deliquescent on exposure to the air. Very soluble in water; soluble in 2 parts of alcohol, 1600 parts of ether, and in 2.5 parts of chloroform at 25° C. (77° F.). Its aqueous solution is neutral to litmus paper, and is strongly lævogyrate. It melts at 151.8° C. (305.3° F.). It leaves no residue on incineration. Hyoscyamine chloraurate melts at 160° C. (320° F.). Atropine chloraurate melts at 136° C. (276.8° F.). Hyoscyne chloraurate melts at 197° C. (386.6° F.). Hyoscyamine picrate melts at 162° C. (323.6° F.). Atropine picrate melts at 175° C. (347° F.). Silver nitrate T.S., when added to a solution of the salt, yields a yellowish-white precipitate which is insoluble in nitric acid, but the washed precipitate is soluble in an excess of ammonia water. Gold chloride T.S., when added to a solution of the salt, yields a precipitate which, when recrystallized from a small quantity of boiling water acidulated with hydrochloric acid, is deposited, on cooling, in minute, lustrous, golden-yellow scales (difference from *atropine*). Platinic chloride T.S. does not form a precipitate with solutions of the salt (difference from *most alkaloids*). If 0.01 Gm. of the salt be added to 5 drops of nitric acid, and evaporated to dryness in a porcelain dish, the residue should yield a violet color upon the addition of alcoholic potassium hydroxide T.S. Sulphuric acid should produce no color when added to Hyoscyamine Hydrobromide (absence of *carbon-*

izable impurities), nor should any color be developed upon the subsequent addition of a drop of nitric acid (absence of *morphine*)." U. S.

Uses.—The medicinal properties and the dose of this salt of hyoscyamine are precisely those of the sulphate, to which it is preferred by some.

Dose, one one-hundred and twentieth to one one-hundredth of a grain (0.0005 to 0.0006 Gm.).

HYOSCYAMINÆ SULPHAS. U. S., Br.

HYOSCYAMINE SULPHATE

(hŷ-qs-cŷ-ā-mī'næ sū'phās)

$(C_{17}H_{23}NO_3)_2 \cdot H_2SO_4 = 671.43$

"The neutral sulphate [$SO_2(OH)_2 \cdot (C_{17}H_{23}NO_3)_2$] of an alkaloid obtained from Hyoscyamus and other plants of the *Solanaceæ*. It should be kept in amber-colored, well-stoppered vials." U. S. "The sulphate, $(C_{17}H_{23}NO_3)_2 \cdot H_2SO_4 \cdot 2H_2O$, of an alkaloid contained in Hyoscyamus Leaves and possibly other solanaceous plants." Br.

Sulfate d'Hyoscyamine, Fr.; Hyoscyaminum Sulfuricum, Schwefelsäures Hyoscyamin, Hyoscyaminsulfat, G.

Although Brandes announced the existence of an alkaloid in the seeds of *Hyoscyamus niger*, the process which he used to obtain it was not successful in other hands. The credit of first isolating the alkaloid *hyoscyamine* or *hyoscyamia* from the plant must be given to Geiger and Hesse, who obtained it as long ago as 1833. Höhn and Reichardt's process, in which the seed is used as the source, is as follows. They treat hyoscyamus seed first with ether to separate fatty matter, then with alcohol acidulated with a few drops of sulphuric acid, and afterwards distil the alcoholic solution. The aqueous residue is to be neutralized with sodium hydroxide, and the liquid precipitated by a solution of tannin. The precipitate, having been placed on a porcelain plate to dry, is mixed while yet moist with an excess of lime, and then exhausted by strong alcohol. The alcoholic solution is treated with sulphuric acid, then with sodium hydroxide, and finally with ether, which dissolves the liberated hyoscyamine. By distilling off the ether a colorless oleaginous liquid is left, which at length concretes. (*J. P. C.*, Mai, 1872, p. 385.)

These investigators gave to hyoscyamine the formula $C_{15}H_{23}NO_3$, but Ladenburg has shown by a study of its decomposition products that it is isomeric with atropine, $C_{17}H_{23}NO_3$. Ladenburg made the most complete study of atropine and hyoscyamine that we have, and has established their relations to each other in a clear light. According to him (*Ber. d. Chem. Ges.*, xiii. pp. 251, 909, and 1549), hyoscyamus contains two alkaloids, a crystalline one, to which the name of *hyoscyamine* is given, and which

is the one hitherto studied under that name, and an amorphous one, which remains in the mother liquor after the removal of the crystallizable alkaloid. It can be extracted by the formation of the gold salt, which is less soluble than hyoscyamine gold chloride. This alkaloid, for which he proposed the name *hyoscine*, and to which he gave the same formula ($C_{17}H_{23}NO$) as hyoscyamine, yields different decomposition products upon decomposition by baryta water. Hyoscyamine treated with boiling baryta water assimilates a molecule of water and splits up into what were called *hyoscimic acid*, $C_9H_{10}O_3$, and *hyoscine*, $C_8H_{15}NO$, but which Ladenburg shows to be simply identical with the decomposition products of atropine, *tropic acid* and *tropine*. The non-existence of Ladenburg's hyoscine of the formula $C_{17}H_{23}NO$ and the truth of the statement that commercial hyoscine is identical with scopolamine (see p. 645) is strongly supported upon large experience in manufacturing these bases by L. Merck. Inasmuch as Ladenburg (*Ber. d. Chem. Ges.*, xii. 941) has succeeded in effecting the synthesis of *atropine* by the combination of tropic acid and tropine (the two decomposition products which are common to the two alkaloids *atropine* and *hyoscyamine*), we must look for the differences between these two to physical and molecular sources rather than chemical.

Hyoscyamine crystallizes in colorless, transparent, silky needles, fusing at $108.5^\circ C.$, is inodorous, of an acrid, disagreeable taste, slightly soluble in water, very soluble in alcohol and ether, and volatilizable with little change if carefully distilled. It is quickly altered by contact with water and an alkali, and when heated with potassium or sodium hydroxide is completely decomposed, with the disengagement of ammonia. It neutralizes the acids, forming crystallizable salts, and is precipitated by infusion of galls. The alkaloid and its salts are very poisonous, and the smallest quantity, introduced into the eye, produces dilatation of the pupil, which continues long.

Hyoscine has been known in commerce as *amorphous hyoscyamine*. The best salts, according to Edelfsen, to prepare and dispense are the *hydrobromide* and *hydriodide*. Hyoscine hydriodide crystallizes from water, in which it is only moderately soluble, in small, hemihedral prisms, which mostly have a slight yellowish color. (See *Hyoscina Hydrobromidum*.)

The double gold chloride, $C_{17}H_{21}NO_4HCl + AuCl_3$, is less soluble than the corresponding gold salt of hyoscyamine, and so serves to separate them when together.

Properties.—The U. S. Pharmacopœia describes hyoscyamine sulphate as "white, indistinct crystals, or a white powder; odorless, having a bitter, acrid taste; deliquescent when exposed to the air. Very soluble in water; soluble in 6.4 parts of alcohol, 2500 parts of

ether, and in 2300 parts of chloroform at $25^\circ C.$ ($77^\circ F.$). Its aqueous solution is levogyrate, and neutral to litmus paper. It melts at $198.9^\circ C.$ ($390.1^\circ F.$). Upon ignition it is rapidly consumed without residue. Hyoscyamine chloraurate melts at $160^\circ C.$ ($320^\circ F.$). Atropine chloraurate melts at $136^\circ C.$ ($276.8^\circ F.$). Hyoscine chloraurate melts at $197^\circ C.$ ($386.6^\circ F.$). Hyoscyamine picrate melts at $162^\circ C.$ ($323.6^\circ F.$). Atropine picrate melts at $175^\circ C.$ ($347^\circ F.$). Barium chloride T.S., when added to an aqueous solution, yields a white precipitate, insoluble in hydrochloric acid. Gold chloride T.S., when added to an aqueous solution, yields a precipitate which, when recrystallized from a small quantity of boiling water, acidulated with hydrochloric acid, is deposited on cooling in minute, lustrous, golden-yellow scales (difference from *atropine*). Platinic chloride T.S. does not form a precipitate with solutions of the salt (difference from *most alkaloids*). If 0.01 Gm. of the salt be added to 5 drops of nitric acid, and evaporated to dryness in a porcelain dish, the residue should yield a violet color upon the addition of alcoholic potassium hydroxide T.S. Sulphuric acid should produce no color when added to Hyoscyamine Sulphate (absence of *carbonizable impurities*). U. S. "A crystalline powder, deliquescent, odorless, having a bitter acrid taste. Melting point $402.8^\circ F.$ ($206^\circ C.$). Soluble in 0.5 part of water, 2.5 parts of alcohol (90 per cent.), very slightly soluble in ether or chloroform. It affords the reactions characteristic of sulphates. A solution in water acidulated with hydrochloric acid yields no precipitate with solution of platinic chloride, but affords with solution of auric chloride a yellow precipitate soluble in boiling water acidulated with hydrochloric acid, and again deposited, as the solution cools, in brilliant, golden-yellow scales (distinction from *atropine*). Heated to redness with access of air it leaves no residue."

Br.

Uses.—Owing to the facts that until very recently commercial hyoscyamine has usually been contaminated with hyoscine, and that few careful studies of a chemically pure hyoscyamine have been made, its exact influence upon the human system is not positively determined. The studies of J. C. Shaw appear, however, to prove that hyoscyamine acts upon the nervous system and the circulation, including the heart and the vasomotor system, precisely as does atropine, except as regards respiration, which appears in most cases to have been slowed rather than increased in rapidity, an indication that hyoscyamine, unlike atropine, is not a respiratory stimulant. Shaw also found that hyoscyamine is less powerful as a mydriatic and more powerful as a soporific than is atropine. On the other hand, in studies upon normal men, Richter could not perceive that hyoscyamine had a tendency to produce sleep. Sydney Ringer, in a careful comparative study of hyoscyamine and atropine in acute

mania, was unable to detect any important differences in the action of the two substances. The dose of commercial hyoscyamine varies greatly according to its purity, but one-fourth of a grain (0.0016 Gm.) of the pure alkaloid has produced violent poisoning, with symptoms similar to those caused by atropine; not more than one-eightieth of a grain (0.0008 Gm.) should be given as a commencing dose.

Dose, one one-hundred and twentieth to one one-hundredth of a grain* (0.0005 to 0.0006 Gm.).

HYOSCYAMUS. U. S. (Br.)

HYOSCYAMUS [Henbane]

(hŷ-qs-cŷ'a-mŷs)

"The dried leaves and flowering tops of *Hyoscyamus niger* Linné (Fam. *Solanaceæ*), collected from plants of the second year's growth, and yielding, when assayed as directed below, not less than 0.08 percent. of mydriatic alkaloids." U. S. "The fresh leaves and flowers, with the branches to which they are attached, of *Hyoscyamus niger*, Linn.; also the leaves and the flowering tops, separated from the branches and carefully dried. Collected from the flowering biennial plants." Br.

Hyoscyami Folia, Br.; Black Henbane, Stinking Nightshade, Insane Root, Poison Tobacco; Jusquiamé noire, Fr. Cod.; Belene, Chenille, Fr.; Herba Hyoscyami, P. G.; Bilsenkraut, Bilsenkrautblätter, G.; Glusquiamo, It.; Beleno, Sp.

There are about eleven species of the genus *Hyoscyamus* known; these are distributed from the Canary Islands over Europe and Northern Africa to Asia.

Hyoscyamus niger, L., *Sp. Pl.* (1753) 179; Willd., *Sp. Plant.* i. 1010; Woodv., *Med. Bot.*, 204, t. 76; Carson, *Illustr. of Med. Bot.*, ii. 19, pl. 66.—Henbane is usually a biennial plant, with a long, tapering, whitish, fleshy, somewhat branching root, not unlike that of parsley, for which it has been eaten by mistake, with poisonous effects. The stem, which rises in the second year, is erect, round, branching, from one to four feet high, and thickly furnished with leaves. These are large, oblong-ovate, deeply sinuated with pointed segments, undulate, soft to the touch, and at their base embrace the stem. The upper leaves are generally entire. Both the stem and leaves are hairy, viscid, and of a sea-green color. The flowers form long, one-sided, leafy spikes, which terminate the branches, and hang downward. They are composed of a calyx with five pointed divisions, a funnel-shaped corolla, with five unequal, obtuse segments at the border, five stamens inserted into the tube of the corolla, and a pistil with a blunt, round stigma. The corolla is of an obscure yellow color, beautifully variegated with purple veins. The fruit is a globular two-celled capsule, covered with a lid, invested with the persistent calyx,

and numerous small seeds, which are discharged by the horizontal separation of the lid. The whole plant has a rank, offensive odor.

H. niger is susceptible of considerable diversity of character, causing varieties which have by some been considered as distinct species. Thus, the plant is sometimes annual, the stem simple, smaller, and less downy than in the biennial plant, the leaves shorter and less hairy and viscid, and the flowers often yellow without the purple streaks. It has been ascertained that much difference of medicinal properties is connected with these diversities of character, and the Pharmacopœias direct the biennial variety as the most efficient.

The plant is found in the northern and eastern sections of the United States, occupying waste grounds in the older settlements, particularly cemeteries, old gardens, and the foundations of ruined houses. It is not, however, a native of this country, having been introduced from Europe. In Great Britain, and on the continent of Europe, it grows abundantly along the roads, around villages, amidst rubbish, and in uncultivated places. Both varieties were formerly cultivated in England, but at present the biennial is chiefly or solely grown. The annual plant flowers in July or August, the biennial in May or June. For an account of the cultivation of the biennial variety at Hitchin, England, see P. J., Feb. 1860.

H. albus, so named from the whiteness of its flowers, is used in France indiscriminately with the former species, with which it appears to be identical in medicinal properties. *Hyoscyamus muticus*, L., of Egypt is said to grow luxuriantly in the temperate zone and to produce a very much larger proportion of alkaloid than does the official English plant. It appeared in the London market in the form of broken stalks with a few capsular fruits and traces of leaves and may become an important source of the alkaloids to the manufacturers.

All parts of *Hyoscyamus niger* are active. The official description of the plant is as follows: "Leaves ovate or ovate-oblong, the lower with a short petiole, the upper sessile, 5 to 25 Cm. long, 2 to 10 Cm. broad, acute, coarsely and angularly toothed or lobed, grayish-green, glandular-hairy, particularly on the lower surface; flowers nearly sessile, with an urn-shaped, unequally 5-toothed calyx and a campanulate, purple-veined corolla, which in the fresh state is yellowish; fruit capsular, 2-celled, and enclosed in the calyx; odor heavy, narcotic; taste somewhat bitter and nauseous. The powder is grayish-green and contains calcium oxalate in single or twin monoclinic prisms about 0.010 Mm. in diameter." U. S.

The mesophyll of the leaf contains small prisms of calcium oxalate. Much of the efficacy of hyoscyamus depends upon the time at which it is gathered. The leaves should be collected soon after the plant has flowered. In the biennial plant, those of the second year are preferred to those of the first. The latter, ac-

cording to Houlton, are less clammy and fetid, yield less extractive, and are medicinally much less efficient. It is said that the plant is sometimes destroyed by severe winters in England, and that no leaves of the second year's growth are then obtainable. This is, perhaps, one of the causes of the great uncertainty of the medicine as found in commerce. The root also is said to be much more poisonous in the second year than in the first.¹

Assay. U. S. (8th Rev.)—"The method to be employed is identical with that given on page 228, with the exception that *twenty-five grammes* of Hyoscyamus in No. 60 powder are to be used, the quantity of chloroform-ether mixture which is added at first increased from 50 Cc. to 100 Cc., and the product at the end of the assay multiplied by 4 instead of 10." U. S.

Properties.—The recent leaves have, when bruised, a strong, disagreeable, narcotic odor, somewhat like that of tobacco. Their taste is mucilaginous and very slightly acid. When dried, they have little odor or taste. Thrown upon the fire, they burn with a crackling noise, as if they contained a nitrate, and at the same time emit a strong odor. Their virtues are completely extracted by diluted alcohol. The aqueous infusion is of a pale-yellow color, insipid, with the narcotic odor of the plant. The leaves were analyzed by Lindbergson, who obtained from them a narcotic principle. They contain a large proportion of potassium nitrate, F. Mahla having obtained, as nearly as he could estimate from his experiments, 2 per cent. of that salt. (*A. J. P.*, 1859, p. 402.) The seeds are very small, roundish, compressed, somewhat kidney-shaped, a little wrinkled, of a gray or yellowish-gray color, of the odor of the plant, and of an oleaginous, bitterish taste. Geiger and Hesse (1833) were the first to demonstrate the existence of an alkaloid in hyoscyamus. Ladenburg stated in 1880 that there are two alkaloids in the plant, —one crystallizable, *hyoscyamine*, and the other amorphous, *hyoscine* (scopolamine, p. 645). (See *Hyoscyaminæ Sulphas*, p. 647, and *Hyoscinæ Hydrobromidum*, p. 645.) Höhn (*Ann. Ch. Ph.*, 157, 98) obtained from the seeds a bitter principle which proved to be a glucoside. He calls it *hyoscypicrin*, and gives it the formula $C_{27}H_{52}O_{14}$.

From experiments made by Hirtz upon the relative medicinal power of extracts from the

seeds and from the leaves, he inferred that the former had ten times the strength of the latter. Henbane leaves yield, by destructive distillation, a very poisonous empyreumatic oil.

Uses.—Hyoscyamus was known to the ancients, and was employed by some of the earlier modern practitioners, but had fallen into disuse, and was almost forgotten, when Baron Störck again introduced it into notice. By this physician and some of his successors it was prescribed in numerous diseases, and, if we may credit their testimony, with the happiest effects; but subsequent experience of its operation has greatly narrowed the extent of its application. It is at present used almost exclusively to relieve *pain*, procure sleep, or quiet irregular nervous action, and is not supposed to exercise any specific curative influence over particular diseases. It is similar in its physiological action to belladonna, and in poisonous doses produces similar symptoms; but it is more of a hypnotic and much feebler. It is chiefly employed to allay nervous irritation, in *hysteria*, and in various pectoral diseases with *cough*, also to prevent griping by the vegetable cathartics. In Europe, where the fresh leaves are readily obtained, it is often applied externally in the shape of lotion, cataplasm, or fomentation, to allay pain and irritation, in *scrofulous* or *cancerous ulcers*, *scirrhus*, *hemorrhoidal*, or other painful *tumors*, *gouty* and *rheumatic swellings*, and *nervous headaches*. The treatment of hyoscyamus poisoning is identical with that of belladonna poisoning. (See *Belladonna*, p. 228.)

Hyoscyamus may be given in fluidextract, solid extract or in tincture. The dose of the leaves is from five to ten grains (0.32 to 0.65 Gm.), that of the seeds somewhat smaller. The extract, or inspissated juice of the fresh leaves (*Extractum Hyoscyami Viride*, Br.), is exceedingly variable in its operation, being sometimes active, sometimes almost inert. The usual dose is from two to three grains (0.13 to 0.20 Gm.), repeated and gradually increased until its effects are obtained. The alcoholic extract (*Extractum Hyoscyami*, U. S.) is more certain. The dose of the extract is from one to two grains (0.065 to 0.13 Gm.), increased *pro re nata*.

Dose, of the leaves, two to five grains (0.13 to 0.32 Gm.).

INFUSIONS

(in-fu'sh)

Apozèmes, Tisanes, Infusions, Fr.; Infusa, P. G.; Infusionen, Aufgüsse, G.; Infusi, It.; Infusiones, Sp.

These are aqueous solutions obtained by treating with water, without the aid of ebulli-

¹ The several products of the hyoscyamus plants are placed by R. Usher (P. J., Aug. 1867) in the following order, as to efficiency; 1, the leaves of the biennial plant of the second year's growth; 2, the biennial plant of the first year; 3, the British annual henbane; 4, the German annual henbane. The last two, though most extensively used, are really nearly valueless, and should always be rejected. The British annual so nearly resembles the biennial of the second year, having flowers, that the two may be easily mistaken for each other; but a sufficient distinction is that the annual plant "possesses no flavor or odor." Besides, the leaves are much shorter, and occasionally there is a pure primrose blossom, which never happens with the biennial, which is beautifully streaked. The biennial plant is so liable to the attacks of worms that at one time little of the second year's growth was collected, and the market was supplied with a very inferior article.

tion, vegetable products only partially soluble in that liquid. The water employed may be hot or cold, according to the objects to be accomplished. Infusions are generally prepared by pouring boiling water upon the vegetable substance and macerating the mixture in a tightly closed vessel until the liquid cools. The soluble principles are thus extracted more rapidly, and, as a rule, in a larger proportion, than at a lower temperature. Some principles, moreover, are dissolved in this manner which are nearly or quite insoluble in cold water. A prolonged application of heat is in some instances desirable, and this may be effected by placing the vessel near the fire. Cold water is preferred when the active principle is highly volatile, when it is injured by heat, or when any substance of difficult solubility at a low temperature exists in the vegetable, which it is desirable to avoid in the infusion. A longer continuance of the maceration is necessary in this case, and in warm weather there is sometimes danger that spontaneous decomposition may commence before the process is completed. When a strong infusion is required, the process of *percolation* may be advantageously resorted to. The water employed should be free from saline impurities, which frequently produce precipitates and render the infusion turbid. Fresh river, rain, or distilled water is usually preferable to water pumped from wells or obtained from springs, except when the latter are known to produce water which will not react with any of the constituents of the infusion.

The substance to be acted on should be sliced or bruised, or in the state of powder, but this last condition is seldom requisite, unless when percolation is employed, and is always inconvenient, as it requires that the infusion should be filtered through paper in order completely to separate the undissolved portion. In other cases it is sufficient to strain it through fine linen or muslin. When percolation is resorted to, the substance should be more or less finely powdered. The United States Pharmacopœia furnishes a general formula for infusions, which is to be used when the proportions are not specified. In the U. S. P. 1880 the strength of such infusions was fixed at 10 per cent. Experience has shown, however, that this was too strong for general purposes, and in the U. S. Pharmacopœia of 1890 and the Eighth Revision, 5 per cent. has been chosen as the limit.

GENERAL FORMULA FOR INFUSIONS, U. S. P.

"An ordinary Infusion, the strength of which is not directed by the physician, nor specified by the Pharmacopœia, shall be prepared by the following formula." *U. S.* "Take of The Substance, coarsely comminuted, *fifty grammes* [or 1 ounce av., 334 grains]; Boiling Water, *one thousand cubic centimeters* [or 33 fluid-ounces, 6½ fluidrachms]; Water, *a sufficient quantity*, to make *one thousand cubic centi-*

meters [or 33 fluidounces, 6½ fluidrachms]. Introduce the Substance into a suitable vessel provided with a cover, pour upon it the Boiling Water, cover the vessel tightly, and let it stand for half an hour in a warm place. Then strain with expression, and pass enough Water through the strainer to make the Infusion measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

"*Caution.*—The strength of Infusions of energetic or powerful substances should be specially prescribed by the physician." *U. S.*

Infusions are usually prepared in glazed earthenware or porcelain vessels fitted with covers. Brande suggests the use of clean metallic vessels, which, when finely polished, retain the heat for a longer time, but they are more liable to chemical alterations, and may sometimes injuriously affect the preparation. Vessels of block-tin are generally well adapted for the purpose.

As infusions do not keep well, especially in warm weather, they should be made extemporaneously and in small quantities. In this country they are usually prepared in the patient's home, and the propriety of their introduction into the Pharmacopœia has been doubted, but it is desirable to have certain fixed standards for the regulation of the medical practitioner, and it is always preferable to direct infusions from the apothecary, for whose guidance official formulas are necessary. Physicians would, indeed, find an advantage in more frequently directing them to be prepared by the pharmacist, instead of leaving their preparation to the carelessness or want of skill of attendants upon the sick. Infusions may be kept during hot weather, and for many months, by straining them *while hot*, and pouring them at once into bottles provided with accurately ground stoppers. The bottle must be brim-full, the stopper being made to displace its bulk of the fluid. A common bottle with a cork stopper may be used, if the softened cork be forced into the full bottle, tied down, and at once dipped into hot sealing wax. The hotter the liquid and the freer from air the better will the infusion keep. Sterilization of infusions by heating them to the boiling point, then preserving in bottles which have been kept hot to destroy germs, and stoppered with sterilized cotton, is effective, particularly if the bottles have a stopcock near the bottom to draw the infusion when wanted. Almén's has proposed a very efficient method of preserving infusions. (*A. J. P.*, April, 1875.) It is as follows: The infusion or decoction is heated for some time in a water bath at 100° C. (212° F.), and the bottle is then fitted with a tight cork, through which a glass tube passes, lightly filled with cotton wool. The cork has a second opening, through which a glass tube passes nearly to the bottom of the bottle; this tube is bent at a sharp angle and has fitted to it a piece of india rubber tubing, to which a pinchcock is attached, by means of

which the contents may be drawn as wanted. By making very concentrated infusions, as suggested by Donovan, with a mixture of three parts of water and one part of alcohol, they may be long kept, and when used can be diluted with water to the proper strength. Thus, if made four times as strong as the official infusion, they may be diluted with three measures of water. The proportion of alcohol would thus be very small, but it might still be medicinally injurious, and infusions should not be prepared in this way unless with the cognizance of the prescriber.

Battley of London introduced a set of preparations, which he called *inspissated infusions*, the advantages of which are that the virtues are extracted by cold water, are not injured by heat used in the evaporation, are in a concentrated state, and are not impaired by time. To prepare them he macerated the material, coarsely powdered, bruised, or finely sliced, in twice its weight of cold distilled water, pressing the solid matter into the liquid repeatedly by a rammer or the hand; then allowed the liquid to drain out, or expressed it in the case of highly absorbent substances, and repeated the process, with an amount of water equal to that which had been separated, until the strength was exhausted. Four or six hours of maceration were usually sufficient. The infusion is then to be concentrated by evaporation, at a temperature not exceeding 71.1° C. (160° F.) to the sp. gr. 1.200, and as much alcohol is to be added as will make its sp. gr. 1.100. These preparations are very analogous to the *fluidextracts* already considered. As a rule, it would probably be preferable to prepare infusions by the process of percolation.

The inspissated infusions must be diluted when administered. The presence of alcohol, though in small quantity, would sometimes be a serious objection. (P. J., x. 129.) Concentrated infusions of the strength of 50 per cent. were introduced into the British Pharmacopœia (1898); they are mostly made by percolation, and are termed "Liquors." (See *Liquor Chirata Concentratus*.) This certainly leads to confusion in nomenclature, and it is difficult to understand why they were not called concentrated infusions, particularly as their almost universal use is for making ordinary infusions by diluting with water.

As we have already treated of the chemical relations and medicinal properties of the substances used in infusion, it would be useless repetition to enlarge upon these points in the following details. We shall touch upon them only in cases of peculiar interest, or where changes requiring particular notice may grow out of the nature of the process.¹

¹ At the several revisions of the Pharmacopœias the following infusions have been dropped from the official lists. We give the former official formulae.

Infusum Catechu. Br. 1885. *Infusion of Catechu*. "Take of Catechu, in coarse powder, one hundred and sixty grains; Cinnamon Bark, bruised, thirty grains; Boiling Distilled Water, ten fluidounces [Imp.

(in-fū'sūm āu-rān'tī-i qom-pōs'ī-tūm)

Tisane d'Écorce d'Orange composée, Fr.; Pomeranzen- und Citronenschalen-aufguss, G.

"Dried Bitter-Orange Peel, cut small, ¼ ounce (Imperial) or 25 grammes; Fresh Lemon Peel, cut small, ¼ ounce (Imp.) or 12.5 grammes; Cloves, bruised, 55 grains (Imp.) or 6.25 grammes; Distilled Water, boiling, 1 pint (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." Br.

meas.]. Infuse in a covered vessel, for half an hour, and strain." Br. 1885. Dose, from one to three fluidounces (30 to 90 Cc.).

Infusum Cusso. Br. 1885. *Infusion of Koussou*. "Take of Koussou, in coarse powder, one-half an ounce [avoirdupois]; Boiling Distilled Water eight fluidounces [Imp. meas.]. Infuse in a covered vessel, for fifteen minutes. Not to be strained." Br. 1885. The whole may be taken for a dose. The *infusion of brayera* (koussou) was very properly dropped at the 1890 revision of the U. S. P. The old formula is as follows: "Brayera, in No. 20 powder, six parts [or one ounce avoirdupois]; Boiling Water, one hundred parts [or one pint]. Pour the Boiling Water upon the Brayera, and let it macerate in a covered vessel until cool. This infusion should be dispensed without straining it." U. S. 1880.

Infusum Jaborandi. Br. 1885. *Infusion of Jaborandi*.—"Take of Jaborandi, cut small, half an ounce [avoirdupois]; Boiling Distilled Water ten fluidounces [Imp. meas.]. Infuse in a covered vessel, for half an hour, and strain." Br. 1885. This preparation is efficient, but from its nauseousness and tendency to sicken the stomach is inferior to the alkaloid or even the fluidextract. Dose, from one to two fluidounces (30 to 60 Cc.).

Infusum Lini. Br. 1885. *Infusion of Linseed*. "Take of Linseed one hundred and fifty grains; Dried Liquorice Root, in No. 20 powder, fifty grains; Boiling Distilled Water ten fluidounces. Infuse in a covered vessel, for two hours, and strain." Br. 1885. This is nearly identical with the *Compound Infusion of Flaxseed* of the U. S. P. 1870. It is a useful demulcent drink in inflammatory affections of the mucous membrane of the lungs and urinary passages. It may be taken ad libitum.

Infusum Matico. Br. 1885. *Infusion of Matico*. "Take of Matico Leaves, cut small, half an ounce [avoirdupois]; Boiling Distilled Water ten fluidounces [Imp. meas.]. Infuse in a covered vessel, for half an hour, and strain." Br. 1885. The dose of this infusion is two fluidounces (60 Cc.).

Infusum Valeriana. Br. 1885. *Infusion of Valerian*.—"Take of Valerian Rhizome, bruised, a quarter of an ounce [avoirdupois]; Boiling Distilled Water ten fluidounces [Imp. meas.]. Infuse in a covered vessel, for one hour, and strain." Br. 1885. The dose of this infusion is two fluidounces (60 Cc.), repeated three or four times a day, or more frequently.

A grateful stomachic in the *dose* of from one-half to one fluidounce (15 to 30 Cc.).

INFUSUM BUCHU. Br.

INFUSION OF BUCHU

(in-fū'sūm bū'zhū)

Infusum Diosmæ, s. Barosmæ; Tisane de Buchu, *Fr. Cod.*; Buchuaufguss, *G.*

"Buchu Leaves, freshly broken, 1 ounce (Imperial) or 50 grammes; Distilled Water, boiling, 1 pint (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

It has the odor, taste, and medicinal virtues of the leaves, and affords a convenient method of administering the medicine.

Dose, from one to two fluidounces (30 to 60 Cc.).

INFUSUM CALUMBÆ. Br.

INFUSION OF CALUMBA

(in-fū'sūm cā-lūm'bæ)

Infusion of Columbo; Tisane de Columbo, *Fr.*; Kolombo-Infusion, Kolomboaufguss, *G.*; Infusion de Colombo, *Sp.*

"Calumba Root, thinly sliced, 1 ounce (Imperial) or 50 grammes; Distilled Water, cold, 1 pint (Imp. meas.) or 1000 cubic centimetres. Infuse for half an hour; strain." *Br.*

The infusion of calumba is likely to spoil very quickly, especially in warm weather. It has been generally supposed that the cold infusion would keep better than the hot, because it contains no starch. Thomas Greenish, however, upon comparing specimens of the two infusions, found that the spontaneous change began sooner in the cold than in the hot, though the former was clearer. Calumba contains starch and albumen. Cold water extracts the latter without the former; hot water the former with comparatively little of the latter, which is partially coagulated by the heat. Both starch and albumen are liable to spontaneous change, but the former is much the more permanent of the two. Hence it is, according to Greenish, that the hot infusion keeps best. Indeed, he ascribes the change which takes place in the starch of the hot infusion chiefly to the agency of a little albumen which has escaped coagulation. According to these views, the best plan of preparing infusion of calumba is to exhaust the root with cold water, by which the starch is left behind, and then to heat the infusion to the boiling point in order to coagulate the albumen. (*A. J. P.*, xviii. 141; from *P. J.*) Upon comparing specimens of the cold and hot infusion, we have not found the results of Greenish fully confirmed. The cold infusion appeared to keep better than the hot. Nevertheless the plan of preparing the infusion above proposed is probably the best. The infusion

of calumba is not colored by salts of iron, and may be conveniently administered in connection with them.

Dose, one fluidounce (30 Cc.), three or four times a day.

INFUSUM CARYOPHYLLI. Br.

INFUSION OF CLOVES

(in-fū'sūm cār-yō-phŷl'i)

Tisane de Girofle, *Fr.*; Gewürznelken-Infusion, Gewürznelkenaufguss, *G.*

"Cloves, bruised, $\frac{1}{2}$ ounce (Imperial) or 25 grammes; Distilled Water, boiling, 1 pint (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

The infusion of cloves affords precipitates with lime water, and with the soluble salts of iron, zinc, lead, silver, and antimony. (Phillips.)

Dose, one fluidounce (30 Cc.).

INFUSUM CASCARILLÆ. Br.

INFUSION OF CASCARILLA

(in-fū'sūm cās-cā-ril'læ)

Tisane de Cascarrille, *Fr.*; Kaskarrillaufguss, *G.*

"Cascarilla, in No. 10 powder, 1 ounce (Imperial) or 50 grammes; Distilled Water, boiling, 1 pint (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

This infusion affords precipitates with lime water, infusion of galls, silver nitrate, lead acetate and subacetate, zinc sulphate, and ferrous sulphate.

Dose, one fluidounce (30 Cc.).

INFUSUM CHIRATÆ. Br.

INFUSION OF CHIRETTA

(in-fū'sūm chī-rā'tæ)

Tisane de Chirette, *Fr.*; Chirettaufguss, *G.*

"Chiretta, cut small, 1 ounce (Imperial) or 50 grammes; Distilled Water, boiling, 1 pint (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

Dose, from one-half to one fluidounce (15 to 30 Cc.).

INFUSUM CINCHONÆ ACIDUM. Br.

ACID INFUSION OF CINCHONA

(in-fū'sūm cīn-phō'næ āc'ī-dūm)

Infusion of Yellow Bark; Infusion of Calisaya Bark; Tisane de Quinquina jaune, *Fr.*; Kalisaya-Rindenaufguss, *G.*

"Red. Cinchona Bark, in No. 40 powder, 1 ounce (Imperial) or 50 grammes; Aromatic Sulphuric Acid, 2 fl. drachms (Imp. meas.) or

12.5 cubic centimetres; Distilled Water, boiling, 1 pint (Imp. meas.) or 1000 cubic centimetres. Mix the Red Cinchona Bark with the Distilled Water in a covered vessel; add the Aromatic Sulphuric Acid; infuse for one hour; strain." Br.

Though the infusion with boiling water is more quickly prepared than the cold infusion, and therefore better adapted to cases of emergency, yet the former is a more elegant preparation, not turbid like the latter, and at least equally efficient. We therefore prefer the process of the U. S. Pharmacopœia 1890, provided it be skilfully conducted.

The U. S. 1890 infusion¹ is an efficient preparation. Water extracts from bark quinine and cinchonine kinates, but leaves behind the compounds which these principles form with the cincho-tannic acid. The simple infusion, therefore, is rather feeble. But the addition of the acid insures the solution of all or nearly all the active matter. Geo. B. Wood placed much reliance on this infusion. It would be best to macerate the bark with the acidulated water some time before it is introduced into the percolator. The infusion of cinchona, made without acid, affords precipitates with the alkalies, alkaline carbonates, and alkaline earths; the soluble salts of iron, zinc, and silver; corrosive mercuric chloride, arsenic trioxide, and tartar emetic; gelatinous solutions; and various vegetable infusions and decoctions, as those of galls, chamomile, calumba, cascarilla, horseradish, cloves, catechu, orange peel, digitalis, senna, rhubarb, valerian, and simaruba. In some instances the precipitate occurs immediately, in others not for several hours. The loss of few, however, of these substances by precipitation diminishes the efficacy of the infusion, as they do not affect the active principles. The alkalies, alkaline earths, and vegetable astringents are really incompatible. As gallic, tartaric, and oxalic acids form salts with quinine of somewhat difficult solubility, the neutral and soluble gallates, tartrates, and oxalates produce in the infusion slight precipitates of corresponding salts of the alkaloids, but these are redissolved by an excess of the acid. Antimony and potassium tartrate does not precipitate the alkaloids. Solutions of iodine are incompatible, forming with the alkaloids insoluble compounds. For an account of the chemical reactions of the infusions of different varieties of cinchona bark, see *A. J. P.*, ix. 128. The simple infusion of cin-

chona may be advantageously administered in cases which require tonic treatment but do not call for the full powers of the bark. The acid infusion has all the powers of cinchona itself.

Dose, one fluidounce (30 Cc.).

INFUSUM CUSPARIÆ. Br.

INFUSION OF CUSPARIA

(in-fū'sūm cūs-pā'ri-æ)

Infusion of Angustura; Tisane d'Angusture, *Fr.*; Angusturaaufguss, *G.*

"Cusparia Bark, in No. 20 powder, 1 ounce (Imperial) or 50 grammes; Distilled Water, boiling, 1 pint (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." Br.

Under the name of *Infusum Angusturæ* this preparation was official in the U. S. Pharm. 1870, made in the proportion of half a troy-ounce of Angustura bark in a pint of water.

Dose, two fluidounces (60 Cc.), repeated every two, three, or four hours.

INFUSUM DIGITALIS. U. S., Br.

INFUSION OF DIGITALIS

(in-fū'sūm dig-i-tāl'is)

Infusion of Foxglove; Tisane de Digitale, *Fr.*; Fingerhutaufguss, Digitalisaufguss, *G.*; Infusion de digital, *Sp.*

* "Digitalis, bruised, fifteen grammes [or 231 grains]; Alcohol, one hundred cubic centimeters [or 3 fluidounces, 183 minims]; Cinnamon Water, one hundred and fifty cubic centimeters [or 5 fluidounces, 35 minims]; Boiling Water, five hundred cubic centimeters [or 16 fluidounces, 435 minims]; Cold Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Upon the Digitalis, contained in a suitable vessel, pour the Boiling Water, and allow it to macerate for one hour. Then strain, add the Alcohol and Cinnamon Water to the strained liquid, and pass enough Cold Water through the residue on the strainer to make the product measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix well." U. S.

"Digitalis Leaves, in No. 20 powder, 60 grains (Imperial) or 6.8 grammes; Distilled Water, boiling, 1 pint (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." Br.

The U. S. P. infusion was improved in the 1890 revision. Cinnamon is used solely as a flavoring ingredient, as it has never been present in sufficient quantity to serve any other purpose. When either the tincture or the aromatic itself is used, precipitation is sure to take place. Cinnamon water is unobjectionable. The present process, which is modelled after the formula of L. G. Blakeslee (*Ph. Era*, 1887, p. 228), yields a preparation which, while not differing essentially in strength from the

¹ *Infusum Cinchonæ*. U. S. 1890. *Infusion of Cinchona*.—"Cinchona, in No. 40 powder, sixty grammes [or 2 ounces av., 51 grains]; Aromatic Sulphuric Acid, ten cubic centimeters [or 162 minims]; Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 391 minims]. Mix the Acid with five hundred cubic centimeters [or 16 fluidounces, 435 minims] of Water, and moisten the powder with thirty cubic centimeters [or 1 fluidounce, 7 minims] of the mixture; pack it firmly in a conical glass percolator, and gradually pour upon it, first, the remainder of the mixture, and afterwards Water, until the infusion measures one thousand cubic centimeters [or 33 fluidounces, 391 minims]." U. S. 1890.

former official infusion, keeps better and does not deposit to any extent. The addition of 10 per cent. of glycerin would be a still greater improvement. D. E. Prall (*A. J. P.*, 1878, p. 423) proved that the abundant precipitate in the old infusion was caused by the tincture of cinnamon, and recommended a simple infusion without any aromatic. J. W. England (*A. J. P.*, 1892, 361) prefers to omit cinnamon entirely from the preparation and add ammonia water (90 minims in a pint). G. L. Humphreys suggests the addition of 8 grammes of powdered cinnamon to the official ingredients, pouring the boiling water upon the digitalis and cinnamon and macerating until the mixture is cold, then following the official directions, and finally filtering the infusion through *unwetted* filtering paper. (See *West. Drug.*, 1897, 162.)

The U. S. infusion is essentially the same as that employed by Withering. It affords precipitates with ferrous sulphate, lead acetate, tannic acid, and infusion of cinchona. The proportion of digitalis is less than half as great in the British preparation, and the dose should be proportionately larger. It will not escape the close observer that the stated dose of digitalis in infusion is much larger than in substance, for which there does not appear to be a good reason, but which accounts for the fact that many physicians assert that they get better results from the infusion than from the digitalis itself.

Dose, of U. S. infusion, two to four fluidrachms (7.5 to 15 Cc.). The British Pharmacopœia, though its infusion has only about half the strength of ours, gives its dose as from two to four fluidrachms (7.5 to 15 Cc.).

INFUSUM ERGOTÆ. Br.

INFUSION OF ERGOT

(in-fū'sūm ɛr'gō-tæ)

Tisane de Seigle ergoté, *Fr.*; Mutterkornaufguss, *G.*

"Ergot, freshly crushed, 1 ounce (Imperial) or 50 grammes; Distilled Water, boiling, 1 pint (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

Dose, two fluidounces (60 Cc.).

INFUSUM GENTIANÆ COMPOSITUM. Br.

COMPOUND INFUSION OF GENTIAN

(in-fū'sūm gēn-ti-ā'næ cōm-pōs'it-tūm)

Tisane de Gentiane composée, *Fr.*; Enzianaufguss, *G.*

"Gentian Root, thinly sliced, $\frac{1}{2}$ ounce (Imperial) or 12.5 grammes; Dried Bitter-Orange Peel, cut small, $\frac{1}{2}$ ounce (Imp.) or 12.5 grammes; Fresh Lemon Peel, cut small, $\frac{1}{2}$ ounce (Imp.) or 25 grammes; Distilled Water, boil-

ing, 1 pint (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

"Take of Gentian, in moderately coarse powder, half a troyounce; Bitter Orange Peel, in moderately coarse powder, Coriander, in moderately coarse powder, each, sixty grains; Alcohol two fluidounces; Water a sufficient quantity. Mix the Alcohol with fourteen fluidounces of Water, and, having moistened the mixed powders with three fluidrachms of the menstruum, pack them firmly in a conical percolator, and gradually pour upon them first the remainder of the menstruum, and afterwards Water, until the filtered liquid measures a pint." *U. S.* 1870.

It is, in our opinion, unfortunate that this, the most esteemed of all infusions, should not have been reinstated in the U. S. P. 8th Revision. We have inserted the formula of U. S. P. 1870, as it will doubtless continue to be largely prescribed. It should be designated, however, as U. S. P. 1870. It has been the custom with some physicians to prescribe a concentrated infusion made with one-fourth the quantity of menstruum directed by the formula of U. S. P. 1870. This permits the use of a valuable tonic with the presence of but a trifling amount of alcohol. This concentrated preparation keeps well, and it may be diluted with the right quantity of the proper menstruum by the pharmacist to make the infusion of U. S. P. 1870. The use of the alcohol is to assist in dissolving the bitter principle, and at the same time to contribute towards the preservation of the infusion, which, without this addition, is very prone to spoil. It has, however, been abandoned by the British Pharmacopœia, and lemon peel substituted.

Dose, one fluidounce (30 Cc.), repeated three or four times a day.

INFUSUM KRAMERIÆ. Br.

INFUSION OF KRAMERIA

(in-fū'sūm kræ-mē'rī-æ)

Infusion of Rhatany; Tisane de Ratanhia, *Fr.*; Ratanhiawurzelaufguss, *G.*

"Krameria Root, bruised, 1 ounce (Imperial) or 50 grammes; Distilled Water, boiling, 1 pint (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

The infusion of rhatany is undoubtedly most efficient when prepared from the root in a state of moderately coarse powder by the mode of percolation with cold water, as directed in the U. S. process of 1870.

Dose, of the infusion, from one to two fluidounces (30 to 60 Cc.).

INFUSUM LUPULI. Br.

INFUSION OF HOPS

(in-fū'sūm lū'pū-lī)

Infusum Humuli, *U. S.* 1870; Tisane de Houblon, *Fr.*; Hopfenaufguss, *G.*

"Hops, freshly broken, 1 ounce (Imperial) or 50 grammes; Distilled Water, boiling, 1 pint (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

The infusion of hops of the U. S. P. 1870 was made exactly like the above, except that the strength was half a troyounce to a pint.

Dose, of the British infusion, from one to two fluidounces (30 to 60 Cc.).

INFUSUM PRUNI VIRGINIANÆ. U. S.

INFUSION OF WILD CHERRY

(în-fû'sûm prô'nî vîr-jîn-î-â'næ)

Tisane d'Ecorce de Cerisier sauvage, *Fr.*; Wildkirschenrindeaufguss, *G.*

* "Wild Cherry, in No. 20 powder, forty grammes [or 1 ounce av., 180 grains]; Glycerin, fifty cubic centimeters [or 1 fluidounce, 331 minims]; Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with sixty cubic centimeters [or 2 fluidounces, 14 minims] of Water, and allow it to macerate for one hour; then pack it firmly in a conical glass percolator, and, having placed the Glycerin in the receiving bottle, gradually pour Water upon the powder and continue percolation until the Infusion measures one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix well." *U. S.*

This is a peculiarly suitable object for official direction, as, in consequence of the volatile nature of one of its active ingredients, and for another reason (see *Prunus Virginiana*), it is better prepared with cold water than in the ordinary mode. The infusion of wild cherry bark is one of the preparations to which the process of percolation or displacement is well adapted. In this way the virtues of the bark can be more rapidly and thoroughly exhausted than by maceration alone. In order to allow time for the reaction necessary to the production of the hydrocyanic acid, an hour's preliminary maceration is directed, which might perhaps be advantageously somewhat lengthened. If kept in a warm place this preparation undergoes a rapid alteration, and even under the best of circumstances it is unstable. According to the experiments of J. B. Moore (*A. J. P.*, 1873, p. 242), confirmed by our own experience, the addition of two fluidounces of glycerin to the pint of menstrum is of great advantage in delaying the change. The U. S. (8th Rev.) has introduced glycerin into the process, but does not add the glycerin to the menstrum, placing it in the receiving bottle. By this method the infusion is not made unnecessarily astringent and the preservative power of the glycerin is retained. When properly made, infusion of wild cherry bark is beautifully transparent, has the color of sherry wine, and the agreeable bitterness and peculiar flavor of the bark.

Dose, from two to three fluidounces (60 to 90 Cc.), from three to six times a day.

INFUSUM QUASSIÆ. Br.

INFUSION OF QUASSIA

(în-fû'sûm quäs'sî-æ)

Tisane de Quassia, *Fr.*; Quassiaaufguss, *G.*; Infusion de quassia amarga, *Sp.*

"Quassia Wood, finely rasped, 88 grains (Imperial) or 10 grammes; Distilled Water, cold, 1 pint (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

Boiling water may be employed when it is desirable to obtain the preparation quickly, but cold water affords a clearer infusion. The fifteen minutes maceration directed in the British Pharmacopœia, considering that cold water is used, appears to us to be too short for the exhaustion of the wood.

Dose, two fluidounces (60 Cc.), three or four times a day.

INFUSUM RHEI. Br.

INFUSION OF RHUBARB

(în-fû'sûm rhê'î)

Tisane de Rhubarbe, *Fr.*; Rhabarberaufguss, *G.*; Infuso di rabarbaro, *It.*; Infusion de rubarbo, *Sp.*

"Rhubarb Root, in thin slices, 1 ounce (Imperial) or 50 grammes; Distilled Water, boiling, 1 pint (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

In order that the rhubarb may be exhausted, it should be digested with the water near the fire, at a temperature somewhat less than that of boiling water. It is customary to add some aromatic, such as cardamom, fennel seed, or nutmeg, which improves the taste of the infusion and renders it more acceptable to the stomach. One drachm of either of these spices may be digested in connection with the rhubarb.

This infusion may be given as a laxative, and is occasionally used as a vehicle for tonic, antacid, or more active cathartic medicines. The stronger acids and most metallic solutions are incompatible with it.

Dose, one to two fluidounces (30 to 60 Cc.).

INFUSUM ROSÆ ACIDUM. Br.

ACID INFUSION OF ROSES

(în-fû'sûm rō'sæ æç'î-dûm)

Infusum Rosæ Compositum, *U. S.* 1870; Compound Infusion of Rose; Acid Infusion of Rose; Tisane de Rose composée, *Fr.*; Saurer Rosenaufguss, *G.*

"Red-Rose Petals, dried and broken, ¼ ounce (Imperial) or 25 grammes; Diluted Sulphuric Acid, 2 fl. drachms (Imp. meas.) or 12.5 cubic centimetres; Distilled Water, boiling, 1

pint (Imp. meas.) or 1000 cubic centimetres. Add the Diluted Sulphuric Acid to the Distilled Water; infuse the Red-Rose Petals in the mixture in a covered vessel for fifteen minutes; strain." *Br.*

The formula of the U. S. P. 1870 is preferable to that of the *Br. Pharm.* on account of the presence of sugar. It is unfortunate, in our opinion, that this elegant infusion was not reinstated at the last revision of the U. S. Pharmacopœia. We append the formula of the U. S. P. 1870: "Take of Red Rose [dried petals] *half a troyounce*; Diluted Sulphuric Acid *three fluidrachms*; Sugar [refined], in coarse powder, *a troyounce and a half*; Boiling Water *two pints and a half*. Pour the Water upon the Rose in a covered glass or porcelain vessel; add the Acid, and macerate for half an hour. Lastly, dissolve the Sugar in the liquid, and strain." *U. S.*

The red rose serves little other purpose than to impart a fine red color and a slight rose and astringent flavor to the preparation, which owes its medicinal virtues almost exclusively to the sulphuric acid. According to J. B. Barnes, one part of glycerin added to eight or nine parts of infusion of rose increases greatly its brightness and transparency. It is refrigerant and astringent, and affords a useful and not unpleasant drink in *hemorrhages* and *colliquative sweats*. It is much used by British practitioners as a vehicle for saline medicines, particularly magnesium sulphate, the taste of which it serves to cover. It is also employed as a gargle, usually in connection with acids, nitre, alum, or tincture of Cayenne pepper.

Dose, two fluidounces (60 Cc.).

INFUSUM SCOPARII. *Br.*

INFUSION OF BROOM

(*in-fū'sūm seq-pā'rī-i*)

Tisane de Genêt à balais, *Fr.*; Besenginsteraufguss, *G.*

"Broom Tops, dried and bruised, 2 ounces (Imperial) or 100 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

This preparation has been introduced in place of the Decoction of Broom of the British Pharmacopœia of 1885. Water thoroughly extracts the virtues of broom, and the large quantity of water in each dose aids the diuretic action.

Dose, from one to two fluidounces (30 to 60 Cc.).

INFUSUM SENEGÆ. *Br.*

INFUSION OF SENEGA

(*in-fū'sūm sēn'ē-gæ*)

Tisane de Polygale de Virginie, *Fr.*; Senegaufguss, *G.*

"Senega Root, in No. 10 powder, 1 ounce (Imperial) or 50 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for half an hour; strain." *Br.*

Dose, one fluidounce (30 Cc.).

INFUSUM SENNÆ. *Br.*

INFUSION OF SENNA

(*in-fū'sūm sēn'næ*)

Senna Tea; Tisane de Séné, *Fr.*; Sennaufguss, *G.*

"Senna, 2 ounces (Imperial) or 100 grammes; Ginger, sliced, 55 grains (Imp.) or 6.25 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

"Take of Senna *a troyounce*; Coriander, bruised, *sixty grains*; Boiling Water *a pint*. Macerate for an hour in a covered vessel, and strain." *U. S.* 1870.

We prefer the coriander of the U. S. P. 1870 to the ginger of the British. The strength of the British preparation has been increased in the present edition of the *Br. Pharm.*, and is now nearly one and a half times as great as that of the U. S. infusion. The infusion deposits, on exposure to the air, a yellowish precipitate, which is said to aggravate its griping tendency; it should, therefore, not be made in large quantities. It is customary to prescribe with it manna and some one of the saline cathartics, which increase its efficacy and render it less painful in its operation. (See *Infusum Sennæ Compositum*.) The cold infusion, especially if made by percolation from the coarsely powdered leaves, while probably not inferior in strength to that prepared with boiling water, is said to be less unpleasant to the taste.

Dose, two fluidounces (60 Cc.).

Off. Prep.—Mistura Sennæ Composita, *Br.*

INFUSUM SENNÆ COMPOSITUM.

U. S.

COMPOUND INFUSION OF SENNA [Black Draught]

(*in-fū'sūm sēn'næ cōm-pōs'it-tūm*)

Tisane de Séné composée, *Fr.*; Infusum Sennæ Compositum, *P. G.*; Wiener Trank, Sennaufguss, *G.*; Infuso di senna con manna, *It.*

* "Senna, *sixty grammes* [or 2 ounces av., 51 grains]; Manna, *one hundred and twenty grammes* [or 4 ounces av., 102 grains]; Magnesium Sulphate, *one hundred and twenty grammes* [or 4 ounces av., 102 grains]; Fennel, bruised, *twenty grammes* [or 309 grains]; Boiling Water, *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims]; Cold Water, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Upon the Senna, Manna, and Fen-

nel, contained in a suitable vessel, pour the Boiling Water, and allow it to macerate for half an hour. Then strain with expression, dissolve the Magnesium Sulphate in the infusion, and again strain. Lastly, add enough Cold Water through the strainer to make the Infusion measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].” *U. S.*

This preparation is the Black Draught of European pharmacy, and it is an excellent form of administering these cathartics in a liquid condition.

Dose, four fluidounces (120 Cc.).

INFUSUM SERPENTARIÆ. Br.

INFUSION OF SERPENTARY

(In-fū'sūm sēr-pen-tā'ri-æ)

Tisane de Serpentaire, *Fr.*; Schlangenzwurzelaufguss, *G.*

“Serpentary Rhizome, in No. 10 powder, 1 ounce (Imperial) or 50 grammes; Distilled Water, boiling, 1 pint (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain.” *Br.*

Dose, one fluidounce (30 Cc.) every two hours in low forms of fever, but less frequently in chronic affections.

INFUSUM UVÆ URSI. Br.

INFUSION OF BEARBERRY

(In-fū'sūm ū'væ ūr'si)

Tisane d'Uva Ursi, *Fr.*; Bärentraubenblätteraufguss, *G.*

“Bearberry Leaves, bruised, 1 ounce (Imperial) or 50 grammes; Distilled Water, boiling, 1 pint (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain.” *Br.*

Dose, from one to two fluidounces (30 to 60 Cc.), three or four times a day.

INJECTIO APOMORPHINÆ HYPODERMICA. Br.

HYPODERMIC INJECTION OF APOMORPHINE

(In-jēc'ti-ō, āp-q-mōr-phī'næ hŷ-pō-dēr'mj-çə)

Injection hypodermique d'Apomorphine, *Fr.*; Subcutane Apomorphineinspritzung, *G.*

“Apomorphine Hydrochloride, 1 grain (Imperial) or 0.1 gramme; Diluted Hydrochloric Acid, 1 minim (Imp. meas.) or 0.1 cubic centimetre; Distilled Water, 110 minims (Imp. meas.) or 10 cubic centimetres or a sufficient quantity. Boil the Distilled Water for a few minutes; cool; add the Diluted Hydrochloric Acid; dissolve the Apomorphine Hydrochloride in the resulting liquid; add, if necessary, sufficient recently-boiled and cooled Distilled Water to produce *one hundred and ten minims* (Imp. meas.) or ten cubic centimetres of the Injection. This Injection should be recently pre-

pared. 110 minims contain 1 grain of Apomorphine Hydrochloride; 100 cubic centimetres contain 1 gramme.” *Br.*

Dose, by subcutaneous injection, from two to eight minims (0.12 to 0.5 Cc.).

INJECTIO COCAINÆ HYPODERMICA. Br.

HYPODERMIC INJECTION OF COCAINE

(In-jēc'ti-ō cō-cā-ī'næ hŷ-pō-dēr'mj-çə)

Injection hypodermique de Cocaine, *Fr.*; Subcutane Cocaineinspritzung, *G.*

“Cocaine Hydrochloride, 33 grains (Imperial) or 1 gramme; Salicylic Acid, ½ grain (Imp.) or 0.015 gramme; Distilled Water, 6 fl. drachms (Imp. meas.) or 10 cubic centimetres or a sufficient quantity. Boil the Distilled Water; add the Salicylic Acid; dissolve the Cocaine Hydrochloride in the solution when cool; add, if necessary, sufficient recently boiled and cooled Distilled Water to produce *six fluid drachms* (Imp. meas.) or ten cubic centimetres of the Injection. 110 minims contain about 10 grains of Cocaine Hydrochloride; 100 cubic centimetres contain 10 grammes.” *Br.*

Dose, by subcutaneous injection, from two to five minims (0.12 to 0.3 Cc.).

INJECTIO ERGOTÆ HYPODERMICA. Br.

HYPODERMIC INJECTION OF ERGOT

(In-jēc'ti-ō ěr'gō-tæ hŷ-pō-dēr'mj-çə)

Hypodermic Injection of Ergotin; Injection hypodermique d'Ergot de Seigle, *Fr.*; Subcutane Mutterkornelspritzung, *G.*

“Extract of Ergot, 100 grains (Imperial) or 10 grammes; Phenol 3 grains (Imp.) or 0.3 gramme; Distilled Water, 220 minims (Imp. meas.) or 20 cubic centimetres or a sufficient quantity. Mix the Phenol with the Distilled Water; boil for a few minutes; cool; add the Extract of Ergot, and, if necessary, sufficient recently boiled and cooled Distilled Water to produce *three hundred and thirty minims* (Imp. meas.) or thirty cubic centimetres of the Injection. This Injection should be recently prepared. 110 minims contain about 33 grains of Extract of Ergot; 100 cubic centimetres contain about 33 grammes.” *Br.*

Dose, by subcutaneous injection, from three to ten minims (0.2 to 0.6 Cc.).

INJECTIO MORPHINÆ HYPODER- MICA. Br.

HYPODERMIC INJECTION OF MORPHINE

(In-jēc'ti-ō mōr-phī'næ hŷ-pō-dēr'mj-çə)

Injection hypodermique de Morphine, *Fr.*; Subcutane Morphineinspritzung, *G.*

“Morphine Tartrate, 50 grains (Imperial) or 5 grammes; Distilled Water, a sufficient

quantity. Dissolve the Morphine Tartrate in sufficient recently boiled and cooled Distilled Water to produce *eleven hundred minims* (Imp. meas.) or one hundred cubic centimetres of the Injection." *Br.*

This solution is made from morphine tartrate in place of the morphine acetate formerly used; this is a great improvement, as the acetate is the most unstable of all morphine salts. The morphine strength of this injection is slightly less than one-half that of the Hypodermic Injection of Morphine of the British Pharmacopœia of 1885. 110 minims contain 5 grains of Morphine Tartrate; 100 cubic centimetres contain 5 grammes.

Dose, by subcutaneous injection, from two to five minims (0.12 to 0.3 Cc.).

INJECTIONES HYPODERMICÆ.

HYPODERMIC INJECTIONS

Under this head are classed preparations which are recognized in the British Pharmacopœia for hypodermic application. These preparations are really of very little value, on account of their proneness to undergo decomposition, and are greatly inferior to the *hypodermic tablets* of various strengths which are now supplied by manufacturing pharmacists—the size of the tablets not varying with the strength, because it is always necessary to use so much diluent in order to make the tablet of sufficient size to handle conveniently. The tablets most used contain apomorphine, morphine, morphine and atropine, atropine, strychnine, pilocarpine, cocaine, hyoscyamine, physostigmine, hyosine, nitroglycerin, or caffeine; each should be readily soluble in fifteen minims of water. These tablets should be made official, since their convenience, permanence, and accuracy in weight have caused them to come into universal use. The selection of the diluent is an important question; very finely powdered cane sugar has been employed, but is apt to produce local irritation and even abscesses. Sodium chloride has also been recommended, but the best diluent seems to be dried neutral sodium sulphate.

IODOFORMUM. U. S., *Br.*

IODOFORM

(1-5-dō-fō'r'mūm)

$\text{CHI}_3 = 390.61$

"Triiodomethane, usually obtained by the action of iodine upon alcohol, in the presence of an alkali or alkali carbonate. Iodoform should be kept in well-stoppered bottles, in a cool and dark place." *U. S.* "Iodoform, or tri-iodomethane, CHI_3 , is a product of the action of iodine on ethylic alcohol in the presence of solution of potassium carbonate." *Br.*

Triiodomethane, Formyltriiodide; Iodoforme, *Fr.* *Cod.*; Iodure de formyle, *Fr.*; Iodoformum, *P. G.*; Jodoform, Carboneum iodatum, Triiodmethan, *G.*; Jodoformio, Triiodometano, *It.*; Yodoformo, *Sp.*

This compound, discovered by Sézallus in 1822, was introduced as a remedy, about the year 1837, by R. M. Glover of London, and Bouchardat of Paris, and was first adopted as official in the U. S. Pharmacopœia of 1870.

Preparation.—Cornéils and Gille published a process in *J. P. C.*, 1852, p. 196. (See *U. S. D.*, 14th ed., 511.) Wittstein's process is an improvement on this, and is as follows: Take two parts of potassium carbonate, two of iodine, one of 95 per cent. alcohol, and five of water, mix them in a retort, and heat the mixture, by means of a water bath, until perfectly colorless; then, after the cooling of the liquid, pour it into a suitable vessel, and allow it to settle. The yellow scaly mass deposited is collected on a filter, washed thoroughly with water, and dried between folds of bibulous paper. As iodoform is very volatile, it must be prepared in closed vessels. The liquid remaining after the deposition of iodoform contains potassium iodate and iodide, which may be decomposed with renewed formation of iodoform by adding potassium dichromate 2 to 3 parts, and hydrochloric acid 16 to 24 parts; this liberates iodine. 32 parts of sodium carbonate, 6 parts of iodine, and 16 parts of alcohol are now added, the liquid is again poured off from the iodoform produced, and the operation repeated if necessary. The formation of the iodoform is represented by the following equation:

Other products, such as potassium iodate, are, however, formed. G. R. Bell (*N. R.*, March, 1882) has practically tried nearly all the processes for the preparation of iodoform, and recommends Filhol's, which is as follows. Put into a long-necked matrass or flask which is supplied with a perforated cork and long supply tube a solution of 200 parts of crystallized sodium carbonate and 1000 parts of distilled water, and add 100 parts of alcohol, heat in a water bath from 60° to 71.1° C. (140° to 160° F.), then gradually add 100 parts of iodine, about ten parts at a time. When the liquid has become colorless, remove the flask from the water bath, and allow it to cool three or four hours, then pour out on a filter; return the filtrate to the flask, add 200 parts of sodium carbonate, 100 parts of alcohol, heat to 71.1° C. (160° F.), and pass a slow current of chlorine gas through the mixture as long as iodine is separated, continuing until the brown liquid is again decolorized. A small excess of chlorine is of no consequence (Hager states that for every 100 parts of iodine it requires the chlorine which can be evolved from about 200 parts of hydrochloric acid by means of manganese dioxide). Let the flask stand twenty-four hours, then throw the contents on a filter and examine the filtrate with chlorine water to see whether it still contains an appreciable amount of iodine compounds, then if necessary subject the filtrate to a second treatment of chlo-

rine gas, adding previously only 20 parts of sodium carbonate and 10 parts of alcohol. Collect the iodoform after twenty-four hours. The filtrate may be concentrated and decomposed by excess of nitric acid, according to the method recommended in Bouchardat's process. The collected crystals of iodoform are now well washed with the smallest quantity of cold distilled water, spread out on bibulous paper, and dried in the open air.

Sulliot and Raynaud have devised a process for making iodoform from kelp ash. (*Bull. Soc. Chim.*, 1889, 3.) S. R. Boyce (*Proc. A. Ph. A.*, 1890, 220) details a process which is essentially that of Sulliot and Raynaud. The advantages claimed for this method are that 98 per cent. of the iodine used is converted into iodoform, and the use of the nitric acid in Filhol's process is obviated. Solution of chlorinated soda is added by drops to a solution of fifty grammes of potassium iodide, five grammes of sodium hydroxide, and forty grammes of acetone in one liter of water. The iodoform, which crystallizes out, should be protected from the light.

Iodoform is now made by electrolysis. An alkaline solution of sodium iodide is electrolyzed in the presence of alcohol, when, iodine being liberated at the anode, iodoform is obtained by the following reaction:

The hydriodic acid formed combines with the sodium hydroxide present, to make sodium iodate, which, with the carbon dioxide, forms the side products. The temperature is kept at about 70° C. during the reaction and a diaphragm is used. The yield of iodoform is about 70 per cent. M. Otto produces iodoform industrially, direct from alkaline iodides, as follows: 100 kg. of water, 300 kg. of alcohol, 10 kg. of sodium carbonate and 55 kg. of potassium iodide are heated to 50° C. in a suitable vessel, and a current of ozone is passed through the mixture. Iodoform is deposited and crystallizes in a pure condition on the sides of the vessel and throughout the fluid itself. The alcohol may be replaced by acetaldehyde, acetone, etc. (*Ap. Ztg.*, 1900, 166.)

The fact, noticed by Lieben in 1870, that many other compounds besides ethyl alcohol yield iodoform when treated with iodine and alkali, led Krämer (*Ber. d. Chem. Ges.*, 1880, p. 1000) to propose the iodoform formation as an exact quantitative test for the presence of acetone in methyl alcohol. This "iodoform test" is now used in testing the purity of methyl alcohol for use in the manufacture of aniline dye colors, as well as the purity of acetone itself. (See *Acetone*.) Heinrich Spindler proposes to make iodoform from the chlorides, bromides, or chloro-bromides of the paraffin series by reaction with an inorganic iodide; thus, if chloroform and anhydrous calcium iodide are heated to 120° C. iodoform is produced. (*Am.*

Drug., 1886, p. 67.) F. Günther recommends mixing alcohol containing 25 per cent. of aldehyde with ten times its weight of solution of sodium hydroxide, adding the iodine, and passing a current of carbon dioxide through the mixture. (*A. Pharm.*, 1887, p. 373.)

Properties.—It is in the form of "a fine, lemon-yellow powder or lustrous crystals of the hexagonal system, having a peculiar, very penetrating and persistent odor, and an unpleasant, slightly sweetish, and iodine-like taste. Soluble in 9391 parts of water, to which it imparts its odor and taste, in 46.7 parts of alcohol, and in 5.2 parts of ether at 25° C. (77° F.); soluble in about 12 parts of boiling alcohol; soluble in chloroform and fixed and volatile oils; slightly soluble in petroleum benzine. Digest in a porcelain dish 0.1 Gm. of Iodoform with 5 Cc. of an alcoholic solution of potassium hydroxide (1 in 20) until it is dissolved, evaporate to dryness on a water-bath, dissolve the residue in 5 Cc. of distilled water, add 2 Cc. of chloroform and an excess of nitric acid, and shake the mixture; the chloroform will assume an intense violet color. Its solutions in neutral solvents are neutral to litmus paper. Iodoform is slightly volatile, even at ordinary temperatures, and in boiling water distils slowly with the vapor of water. At about 115° C. (239° F.) it melts to a brown liquid, and at a higher temperature emits vapors of iodine, leaving behind a carbonaceous mass, which, upon full combustion, should leave not more than 0.1 per cent. of residue (limit of fixed impurities). On being dried over sulphuric acid, the loss in weight should not exceed 1 per cent. If 2 Gm. of Iodoform be thoroughly shaken with 10 Cc. of water, the filtrate should be colorless and free from bitter taste (absence of soluble yellow coloring matters, picric acid, etc.); it should not affect the color of litmus paper (absence of free acids), nor should it be rendered more than faintly opalescent by silver nitrate T.S. (absence of soluble iodides)." *U. S.* "Very slightly soluble in cold water, soluble in 80 parts of cold or 10 parts of boiling alcohol (90 per cent.), in 5 parts of cold ether, soluble also in chloroform, carbon bisulphide, or fixed and volatile oils, and, sparingly, in benzol; the solutions do not affect litmus. When heated it first melts to a brown liquid, then gives off brown and violet vapors, leaving a black residue which entirely disappears on continued incineration. When warmed with an alcoholic solution of potassium hydroxide and the resulting liquid acidulated with nitric acid, iodine is liberated, the mixture becoming brown, and, when cold, blue on the addition of mucilage of starch. Water with which Iodoform has been shaken should be colorless and not bitter (absence of soluble yellow coloring matters, picric acid, etc.), and should not yield any reaction with the tests for iodides." *Br.* Iodoform is a volatile substance, soft to the touch, and totally devoid of corrosive properties. With potassium hydroxide in

solution, it is decomposed, yielding potassium formate and iodide. Hence these two principles are incompatible in prescriptions. The specific gravity of iodoform, about which there has been a controversy, was determined by J. Percy Remington to be 4.000; the specific gravity of 2.000 as given in the U. S. P. 1890 was undoubtedly due to the operator taking the specific gravity of iodoform in water, and when this is done it is practically impossible to free the crystals from admixed air; the result was reached by using a saturated solution of iodoform in pure kerosene as the liquid, and by a simple calculation obtaining the equivalent in water. Iodoform is sometimes met with in commerce adulterated with water; Vulpus (*Ph. Cb.*, 1894) on examination detected 13 per cent. in one specimen.

Uses.—Maitre, who has studied the physiological effects of iodoform on men, states that from a dose of 30 or 40 centigrammes (about 5 or 6 grains) no effects are observed except a slight increase of appetite. Two hours after it has been taken, the presence of iodine can be detected in the urine and the saliva, and nearly three days elapse before the whole is eliminated. (See also Höyges, *J. P. C.*, Juillet, 1867.) It passes off also with the lacteal secretion. Given to dogs in much larger doses, several grammes for example, it produces narcotic effects, and two stages in its operation have been noticed; the first is marked with more or less prostration, with symptoms of intoxication, the animal tottering, inclining to one side with the head falling, with loss of appetite, but without vomiting. The next day, unless a very large dose has been given, complete recovery takes place. A still larger dose induces the second stage, characterized by a remarkably intense excitation, with anxious breathing, strong and short pulse, a true opisthotonos, sometimes very striking, and convulsive movements of the paws, especially the hinder ones. After death fatty degeneration of the heart, liver, and kidneys may be found. (A. Höyges.) The very free use of iodoform in Germany as an antiseptic dressing to wounds, ulcers, etc., has led to many cases of poisoning. In the most characteristic and severe cases the phenomena of iodoform poisoning resemble somewhat those of meningitis; they are headache, somnolence deepening into stupor, contracted, motionless pupils, abnormal quiet or restlessness ending in active delirium, with, however, a normal temperature and an exceedingly rapid pulse.¹ In cases of this character death almost always follows, although the symptoms may have developed abruptly and the dressing has at once been removed. In

other cases the principal symptoms are general malaise and depression, faintness, headache, loss of appetite, and a persistent iodoform taste in the mouth. In some cases there is a slight temporary increase of temperature. Mental depression or excitement is especially noticed. Finally the pulse becomes accelerated, soft, and feeble; in some cases the pulse is very rapid,—from 150 to 180,—while the temperature remains normal, or only slightly elevated. It is asserted by Samter and Retzlaff (*T. G.*, 1889) that potassium bromide is an antidote in poisoning with iodoform, its antidotal powers being due to the fact that it exceeds all other salts in its power of dissolving iodine compounds.

Iodoform, though containing 29 parts in 30 of its weight of iodine, is not locally irritant, but anæsthetic and antiseptic. It is said, when employed as a suppository, to produce unconsciousness of the act of defecation. In the form of vapor, it possesses anæsthetic properties, but inferior to those of chloroform. On account of its large proportion of iodine, it was supposed to be capable of replacing that element and the iodides as a remedy, with the advantages of being non-irritant, and of having an organic nature, qualities which favor its absorption and assimilation. The principal diseases in which it has been tried are *goitre*, *ricketts*, *scrofula*, *phthisis*, *syphilis*, and *glandular tumors*. It may be given in doses of from one to three grains (0.065 to 0.2 Gm), three or four times a day, in pill form, but it has not met the expectation of its early advocates, and is not much used internally. The chief value of iodoform in practical medicine is as an external application. It has long been used in cases of painful ulcers, especially when of syphilitic origin, but has been found to act almost equally well in indolent leg ulcers and other non-specific abrasions, and will even produce marked relief in open cancers.² Within the last few years it has been freely employed as an antiseptic dressing to wounds, and the testimony from surgeons is so strong that it is difficult to avoid believing that it is one of the most certain remedies of the class. The good results which have been achieved have led to a series of studies of its action upon septic organisms, with results which are apparently at variance with practical surgical teachings,³ and which seem to prove that iodoform itself has little power as a bactericide. When, however, it is brought in contact with the living surface of a wound it undergoes

¹ *Diagnostic Sign of Iodic Poisoning.*—Burlureaux affirms that if a piece of silver be placed in the mouth of a person suffering from iodoform poisoning, immediately the taste of garlic will be perceived, and if some of the saliva be mixed with calomel, a canary-yellow precipitate of mercurial iodide will be obtained. The most that such a test can accomplish is to show that the patient is under the influence of some compound of iodine.

² *Iodoform in Burns.*—At a discussion of the International Congress of Dermatology, in 1889, the conclusion was reached that the best treatment of burns in the beginning is to cut the bullæ, wash the part with a very weak solution of salt, and then dress with iodoform gauze or a pomade of iodoform, and cover with oil silk. In the later stages, after the separation of the eschars, according to Hebra, iodoform retards cicatrization, while a one or two per cent. solution of resorcinol hastens epithelium formation.

³ For a more elaborate discussion of these investigations, the reader is referred to H. C. Wood's *Treatise on Therapeutics*, 12th edition.

a slow chemical change, resulting in the liberation of iodine, which element has a distinct influence upon the development of septic organisms. Moreover, iodoform appears to have a specific influence upon human tissue, by which it prevents the formation of purulent or serous exudations, and greatly diminishes the soil in which the bacteria develop. The local application of iodoform in surgical tuberculosis has received the highest commendation from numerous surgeons. In the treatment of tuberculous abscesses, in tuberculous empyema, in tubercular joints, in non-suppurating tuberculous glands, and even in tuberculous peritonitis, numerous cures have been claimed. That iodoform has a specific influence upon the tubercle bacillus would seem to follow from the experiments of Gosselin of Caen, who found that guinea pigs saturated with iodoform are incapable of contracting tuberculosis.

The manner of application varies with different surgeons. Verneuil, who has had an enormous experience, prefers in the treatment of abscesses and of tuberculous glands, and in most other cases, the injection of a 5 per cent. ether solution. Others prefer glycerin as a vehicle, especially in empyema cases, while others, especially in peritonitis, dust the dry powder over the surface which has been laid open. In uterine affections, vaginal suppositories made by incorporating 5.5 grains of iodoform with 2.5 drachms of cacao butter have been largely used, and similar rectal suppositories have been employed with asserted advantage in hemorrhoids, prostatic enlargement, and in fissures of the anus. In surgical dressings with iodoform the powder is usually sprinkled freely upon the wounds and secured in place by a dry dressing. *Iodoform gauze*, or *iodoform cotton wool*, may be made by saturating suitable material with a concentrated ethereal solution and afterwards drying.

The maximum amount of iodoform which may be used with safety as an external application is uncertain. Langenstein attributes a fatal result to one drachm, while one hundred and twenty grains have certainly caused death. Not more than half a drachm of iodoform should be ordinarily applied to a wound, although in cases of tuberculosis the surgeon is warranted in taking the risk of larger amounts. Verneuil sometimes injects at one sitting 75 grains of the iodoform.

One of the principle obstacles to its employment is the odor, which, to some patients, is unbearable. Many methods of disguising the odor have been recommended, but in our experience the large quantity required of each deodorizing agent would preclude its employment. Tannin has been recommended, but, as this operates by decomposing the iodoform, it is not to be thought of in this connection. Probably the best class of substances to use are the volatile oils, such as anise, peppermint, fennel, bergamot, almond, etc., tonka, coffee, and balsam of Peru, although the latter acts by

forming a compound, and the aim should be not to destroy the odor, but so to modify it as to remove its objectionable features. Olive oil saturated with camphor is said to dissolve 6 per cent. of iodoform, and is preferred by some surgeons.

Dose, one to five grains (0.065 to 0.32 Gm.).

IODOLUM. U. S.

IODOL

(I-ōd'q-lūm)

$\text{C}_4\text{I}_4\text{NH} = 566.17$

"Tetraiodopyrrol, a derivative of the base pyrrol, obtained by the direct action of iodine upon the base in the presence of alcohol. Iodol should be preserved in amber-colored bottles, protected from light." *U. S.*

Tetraiodopyrrol, Pyrrol Tetraiodide; Jodol, Tetraiodpyrrol, *G.*; Jodolo, *It.*; Yodol, *Sp.*

Preparation.—Iodol was discovered by Silber and Ciamician, and is made from the pyrrol obtained in Dippel's oil (bone oil), which, after purifying, is treated with a solution of iodine in potassium iodide, when the tetraiodide (iodol) precipitates. It is purified by redissolving in hot alcohol, and again precipitated by the addition of water. It contains nearly 89 per cent. of iodine.

Properties.—It is officially described as "a light grayish-brown, crystalline powder, without odor or taste. It is soluble in about 4900 parts of water, 9 parts of alcohol, 1.5 parts of ether, and 105 parts of chloroform at 25° C. (77° F.); soluble in fixed oils. It is soluble in concentrated sulphuric acid, producing a green solution gradually changing to brown. When heated to 100° C. (212° F.) it remains unchanged, but at a temperature of 140° to 150° C. (284° to 302° F.) it is decomposed with the liberation of violet iodine vapors. When ignited it should leave not more than 0.1 percent. of residue (limit of inorganic impurities). If 0.5 Gm. of Iodol be shaken with 100 Cc. of water and filtered, the filtrate should not be made more than slightly opalescent by silver nitrate T.S. (absence of hydriodic acid or soluble metallic iodides). If 0.5 Gm. of Iodol be shaken with 100 Cc. of water and filtered, the filtrate should not communicate more than a light yellowish tinge to chloroform (absence of appreciable amount of free iodine)." *U. S.*

Uses.—When given in sufficient dose to animals, iodol causes emaciation, albuminous urine, fall of temperature, general loss of muscular power, and finally death from fatty degeneration of the liver and kidneys and other tissues. That iodol applied externally is capable of producing constitutional symptoms is shown by C. Lauenstein (*T. G.*, 1887, 768), in a case in which

the surgical use of the drug caused dizziness, marked rise in the temperature, vomiting, small irregular pulse of 136, albuminous urine, and apathy which did not subside for four days. Iodine was found in the urine for twelve days. Pallin also reports a case with similar symptoms. That iodol is a less dangerous topical application than iodoform is due to its slower absorption. Iodol may be employed for all purposes for which iodoform has been used. It has been found very valuable in the treatment of *tuberculous laryngitis*, and may be blown into the larynx directly upon the ulcers without causing irritation. It has been used with asserted great success in the treatment of blennorrhagic and simple *vaginitis*, in *chancres* and other *ulcers*, in suppurative *adenitis*, and as an antiseptic dressing to *wounds*. Mazzoni's original solution was: iodol, one part; alcohol, sixteen parts; glycerin, thirty-four parts. One drachm of iodol forms with one ounce of ether a clear brown solution, which may be applied by the spray or brush to the nasal and other mucous membranes, on which it leaves a coating of iodol. Iodol pastilles are prepared by Wolfenden from one grain of iodol, one minim of glycerin, and eighteen grains of glyco-gelatin, and are by him strongly recommended for *laryngitis*. Iodol has also been used as an internal remedy. Assaky states that its effects in *tertiary syphilis* and in *scrofula* are extraordinary. Good effects have also been claimed for it in *diabetes*. Assaky and Reck have given thirty grains (1.9 Gm.) a day with asserted good results.

Dose, two to four grains (0.13 to 0.26 Gm.).

IODINE

(i-ô'düm)

I = 125.00

"It should contain not less than 99 percent. of pure Iodine, and be kept in glass-stoppered bottles, in a cool place." U. S. "A solid non-metallic element obtained from the ashes of sea-weeds and from native iodides and iodates." Br.

Iodinium, U. S. 1870; Iode sublimé, Fr. Cod.; Iode, Fr.; Jodium, P. G.; Jod, G.; Jodo, It.; Yodo, Sp.

Iodine is a non-metallic element, discovered in 1812 by Courtois, a soda manufacturer of Paris. It exists in certain marine vegetables, particularly the fuci or common sea weeds, which have long been its most abundant natural source. It has been detected in some fresh water plants, among which are the water cress, brooklime, and fine-leaved water hemlock; also in the ashes of tobacco, and of Honduras sarsaparilla. (Chatin.) It has been found in the beet-root of the grand duchy of Baden. (Lamy.) Macadam detected a trace of iodine in 100 gallons of water used for domestic purposes in

Edinburgh, in several of the domestic animals, and in man. He detected it also in potatoes, beans, peas, wheat, barley, and oats. (P. J., Nov. 1854, p. 235.) Iodine is, moreover, found in the animal kingdom, as in the sponge, the oyster, various polypi, cod liver oil, and eggs, and, in the mineral kingdom, in sea water in minute quantity, in certain salt springs, as silver iodide in a rare Mexican mineral, in a zinc ore of Silesia, in native sodium nitrate, and in some kinds of rock salt. It is now obtained commercially from one of these sources—viz., from the native sodium nitrate, or Chili saltpetre, with which it occurs as sodium iodate. The production of the province of Tarapaca (Chili) has assumed large dimensions within recent years, as a result of higher prices established by a combination of Scotch, French, and South American producers. The exportations of iodine from Chili amounted in 1904 to 458,206 kilos, while the stock on hand at the beginning of that year in London, was 713,690 kilos. Bussy has obtained iodine, in the proportion of one part in five thousand, from the coal gas liquor of the gas works of Paris. It was first discovered in the United States in the water of the Congress Spring, at Saratoga, by William Usher. It was detected in the Kanawha saline waters by Emmet, and it occurs in the bittern of the salt works of Western Pennsylvania, in the amount of about eight grains to the gallon. In sea weeds the iodine exists in the state probably of sodium iodide. In different countries sea weeds are burned for the sake of their ashes, the product being a dark-colored fused mass called *kelp*. This substance, besides sodium carbonate and iodide, contains more or less sodium chloride, potassium chloride, sodium sulphate, etc. The deep sea fuci contain the most iodine, and when these are burned at a low temperature for fuel, as is the case in the island of Guernsey, their ashes furnish more iodine than does ordinary kelp. (Graham.) According to Geo. Kemp, the laminarian species, especially *Laminaria digitata*, *L. saccharina*, and *L. bulbosa*, which are deep water sea weeds, and contain more potassium than sodium, are particularly rich in iodine.

Preparation.—Although most largely produced in South America, iodine is still obtained from kelp, and in Great Britain is manufactured chiefly at Glasgow. The kelp, which on an average contains 1-224th part of iodine, is lixiviated with water, in which about half dissolves. The solution is concentrated until a pellicle forms and allowed to cool, whereby nearly all the salts, except sodium iodide, are separated, they being less soluble than the iodide. The remaining liquor, which is dense and dark-colored, is made very sour by sulphuric acid, which causes the evolution of carbon dioxide, hydrogen sulphide and sulphurous acid, and the deposition of sulphur. The liquor is then introduced into a leaden still, and distilled with manganese dioxide into a

series of glass receivers, inserted into one another, in which the iodine is condensed. In this process the sodium iodide is decomposed, and the iodine evolved according to the reaction:

which leaves as residue manganous sulphate and sodium sulphate.¹ In this treatment much care is needed to avoid the liberation of chlorine from chlorides present, which will form volatile iodine trichloride and so occasion loss. This can be avoided by heating the acidified iodide solution with ferric chloride, when iodine is liberated according to the reaction:

The methods for the separation of the iodine from its combinations in the mother liquors as practised in South America may be divided essentially into three classes. 1. The mother liquors after the crystallization of the saltpetre without further concentration are treated with a solution of sodium sulphite of strength corresponding to the amount of iodine present; the iodine is liberated according to the reaction:

the iodine thus separated from the sodium iodate is filtered through linen cloth, washed, pressed, and sublimed. 2. The mother liquors are treated with sodium sulphite or bisulphite until the precipitated iodine is converted into HI, and this is precipitated as cuprous iodide by a solution of copper sulphate and sodium sulphite. 3. The amount of iodine is increased by fractional evaporation and crystallization of the mother liquors, and then, after adding the calculated amount of sodium bisulphite, the iodine is distilled off from the acidified liquor. (*Dingler's Polytech. Journ.*, 231, p. 375.)

¹ The methods formerly practised for obtaining iodine from sea weeds were accompanied with great loss. A notable improvement over the old kelp processes are the "char" and "wet" processes of E. C. C. Stanford (*J. Soc. Chem. Ind.*, 1855, p. 518), which show the following results when compared with the old processes. *Kelp process*: per cent. utilized, 18; kelp, 18 tons, yield salts 9 tons, and iodine 270 lbs.; residues, kelp waste 18 tons, valueless. *Char process*: per cent. utilized, 36; char, 36 tons, yield salts 15 tons and iodine 600 lbs.; residues, charcoal 36 tons, tar, and ammonia. *Wet process*: per cent. utilized, 70; water extract, 33 tons, yield salts 20 tons and iodine 600 lbs.; residues, algin 20 tons, cellulose 15 tons, dextrin, etc.

Still another improvement was made in Germany (A. James, German Patent No. 95,063, of March 17, 1897), whereby over 91 per cent. of the iodine present in the sea weed has been recovered. Sea weed either wet or dry is immersed in sea water that has previously been treated with quicklime to precipitate the magnesia and give a distinctly alkaline reaction. The sea weed in the proportion of about one ton to the cubic meter of water is left immersed for twelve hours, during which time about 60 per cent. of the iodine is dissolved. It is then leached for six hours, each time in a second and third portion of prepared sea water. The combined extraction waters are then treated with ferrous sulphate, to coagulate mucilaginous matter, neutralized with sulphuric or hydrochloric acid, and the iodine then set free with an oxidizing agent like nitric acid or persulphate of ammonium, 1.5 kilos of nitric acid being required per cubic meter of solution. Iodine thus freed is extracted with petroleum naphtha, this solution being agitated with caustic alkali to form iodide and iodate, which are then treated in the usual manner.

The British Pharmacopœia of 1864 purified iodine as follows: Take of Iodine of Commerce *one ounce*. Introduce the Commercial Iodine into a porcelain capsule of a circular shape, cover this as accurately as possible with a glass flask filled with cold water, and apply to the capsule the heat of boiling water for twenty minutes. Let the flask be now removed, and should colorless acicular prisms of a pungent odor be found attached to its bottom, let them be separated from it. This being done, the flask is to be restored to its previous position, and a gentle and steady heat (that of a gas-lamp answers well) applied, so as to sublime the whole of the iodine. Upon now allowing the capsule to cool, and lifting off the flask, the purified product will be found attached to the bottom of the latter. When separated it should be immediately enclosed in a bottle furnished with an accurately ground stopper. In this process a short preliminary sublimation by the heat of a water bath is ordered, in which the bottom of a glass flask filled with cold water is the refrigerator. The object of this is to separate any cyanogen iodide that may happen to be present. Should the flask, upon its removal, have attached to its bottom white acicular crystals, these will be the iodide in question, and must be rejected. The flask having been replaced, heat is again applied until the whole of the iodine has sublimed and attaches itself to the cool bottom of the flask.

Water has sometimes been found in iodine to the extent of 15 or 20 per cent. If considerable, it is easily discovered by the iodine adhering to the inside of the bottle. Bolley estimates its amount by rubbing together, until the odor of iodine disappears, 30 grains of iodine with about 240 of mercury, in a small weighed porcelain dish, using a small weighed agate pestle. When complete combination has been effected, the whole is placed in a water bath to dissipate the water. The loss of weight gives the amount of water in the iodine. (*Chem. Gaz.*, March 15, 1853, p. 118.) The presence of water is injurious only as it renders all the preparations of iodine weaker than they should be. In the former Ed. Pharmacopœia, directions were given to dry it, by placing it "in a shallow basin of earthenware, in a small confined space of air, with ten or twelve times its weight of fresh-burnt lime, till it scarcely adheres to the inside of a dry bottle."

Properties.—Iodine is described by the U. S. Pharmacopœia as "heavy, bluish-black, dry and friable, rhombic plates, having a metallic lustre, a distinctive odor, and a sharp and acrid taste. Specific gravity: 4.948 at 17° C. (62.6° F.). Iodine imparts a deep brown, evanescent stain to the skin, and slowly destroys vegetable colors. Soluble in about 5000 parts of water, and in 10 parts of alcohol at 25° C. (77° F.); freely soluble in ether, chloroform, or carbon disulphide; its solution in alcohol or in an aqueous solution of potassium

iodide has a reddish color; its solution in chloroform or carbon disulphide has a violet color. It volatilizes slowly at ordinary temperatures. When heated to about 114° C. (237.2° F.), it fuses, and is gradually dissipated in the form of a purple vapor, leaving no residue. With starch T.S. a dark blue color is produced." *U. S.* "Soluble in about 5000 parts of water, but freely dissolved by alcohol (90 per cent.), ether, chloroform, or solution of potassium iodide. The aqueous solution strikes a deep blue color with mucilage of starch. It sublimes without residue, and the portion that first comes over does not include any slender colorless prisms emitting a pungent odor (absence of iodine cyanide)." *Br.* It is a volatile substance, and evaporates even at common temperatures. Its vapor has the sp. gr. 8.7, being the heaviest aëriiform substance known. If inhaled mixed with air, it excites cough and irritates the nostrils. When it comes in contact with cool surfaces, it condenses in brilliant steel-gray crystals. Iodine is freely soluble in alcohol and ether, but requires 5000 times its weight of water to dissolve it. If water stands on iodine for some time, especially in a strong light, it apparently dissolves more iodine, but the result depends upon the formation of hydriodic acid, in a solution of which iodine is more soluble than in water. The solution of iodine in water has no taste, a feeble odor, and a light-brown color; its solution in alcohol or ether is nearly black. Its solubility in water is very much increased by the addition of certain salts, as sodium chloride, ammonium nitrate, or potassium iodide, and the same effect is produced, to some extent, by tannic acid. Its solution in tannic acid is called *iodo-tannin*, of which Soequet and Guillemond made a syrup for internal and an aqueous solution for external use. For the formulas, see *B. F. M. R.*, 1854, p. 181. It is also soluble in glycerin, as ascertained by Cap in 1854. According to I. Walz, glacial acetic acid is an excellent solvent of iodine, at least equal to alcohol. When the acid is heated to boiling with excess of iodine, and then allowed to cool slowly, it deposits iodine in beautiful large slender crystals, sometimes half an inch long, much larger and more abundant than those formed from other solutions. (*Chem. News*, 1873, p. 233.) In chemical characters iodine resembles chlorine, but its affinities are weaker. It combines with most of the non-metallic and nearly all the metallic elements, forming a class of compounds called iodides. Some of these are official, as the iron, mercury, lead, potassium, sodium, strontium, and sulphur iodides. It forms with oxygen one oxide, *iodic oxide*, I_2O_5 and two acids, *iodic*¹ and *periodic*, and with hydrogen a gaseous acid, called *hydriodic acid*.

Tests.—Iodine, in most cases, may be recognized by its characteristic purple vapor; but, where this cannot be made evident it is detected unerringly by starch, which produces with it a deep-blue color. The test was discovered by Colin and Gaultier de Claubry, and is so delicate that it will indicate the presence of iodine in 450,000 times its weight of water. In order that the test may succeed, the iodine must be free, and the solutions cold. To render it free when in combination, as it always is in the animal fluids, a little nitric acid, free from iodine, must be added to the solution suspected to contain it. Thus, in testing urine for iodine, the secretion is mixed with starch, and acidulated with a drop or two of nitric acid, when, if iodine be present, the color produced will vary from a light purple to a deep indigo blue, according to the amount of the element present. Sometimes in mineral waters the proportion of iodine is so minute that the starch test, in connection with nitric acid, gives a doubtful coloration. In such cases, Liebig recommends the addition to the water of a very small quantity of potassium iodate, followed by a little starch and hydrochloric acid. Assuming the iodine to be present as hydriodic acid, the liberated iodic acid sets free the iodine of the mineral water, and becomes itself deoxidized, thus increasing the amount of the free iodine:

This test would be fallacious if iodic acid, mixed with hydrochloric acid, colored the starch, but this is not the case. Still, Liebig's test is inapplicable in the presence of reducing agents, such as sulphurous acid, which would give rise to free iodine from the test itself, independently of the presence of the element in the water tested. (W. Knop.) The U. S. P. gives the following tests: "A solution of iodine in chloroform should be perfectly clear and limpid (absence of moisture). To determine the presence of cyanogen, chlorine, or bromine, proceed as follows: Triturate 0.5 Gm. of finely powdered Iodine with 20 Cc. of water, and filter the solution. To one-half of this solution, in a test-tube, carefully add tenth-normal sodium thiosulphate V.S., until the solution is just decolorized. Then add a few drops of ferrous sulphate T.S., and subsequently a little sodium hydroxide T.S., and heat the mixture gently. On now adding a slight excess of hydrochloric acid, the liquid should not assume a blue color (absence of iodine cyanide). To the other half of the aqueous filtrate, in a test-tube, add a slight excess of silver nitrate T.S., shake the liquid actively, allow the precipitate to subside, and, having poured off the clear, supernatant liquid completely, shake the precipitate with a mixture of 1 Cc. of ammonia water and 9 Cc. of water, and filter. Upon the addition of a

¹R. H. Brett of Liverpool, has found that when a small portion of the alkaloïds, or their salts, is mixed with about an equal portion of iodic acid and a few drops of water, and the mixture gently heated,

a succession of distinct explosions, attended by the evolution of gas, takes place. Brett finds that this phenomenon does not occur with other organic substances, and suggests it as a general test for alkaloïds. (*P. J.*, Nov. 1854.)

slight excess of nitric acid to the filtrate, not more than a slight opalescence should make its appearance (limit of *chlorine* or *bromine*).

Assay.—Place about 0.5 Gm. of Iodine in a tightly stoppered weighing-bottle and weigh accurately; add 1 Gm. of potassium iodide and dissolve in 50 Cc. of water, then add tenth-normal sodium thiosulphate V.S. until the liquid is decolorized. The number of Cc. of tenth-normal sodium thiosulphate V.S. consumed, when multiplied by 1.259, and divided by the weight of the Iodine taken, gives the percentage of pure Iodine present." *U. S.* The British Pharmacopœia states that "a solution of Iodine in *chloroform* should be perfectly clear (absence of moisture). Each gramme, dissolved in 50 cubic centimetres of water containing 2 grammes of *potassium iodide*, should require for decoloration at least 78.4 cubic centimetres of the *volumetric solution of sodium thiosulphate*." Carey Lea proposes chromium trioxide as a substitute for the nitric acid for the liberation of iodine, as a more delicate test. It may be most conveniently applied by first adding starch to the liquid to be tested, and then a little diluted solution of potassium dichromate, enough to cause a pale yellow color, followed by a few drops of hydrochloric acid. (*Am. J. Sci.*, xlii. 109.) Another test for iodine, proposed by Rabourdin, is chloroform, by the use of which he supposes that the element may be not only detected in organic substances, but approximately estimated. Thus, if 150 grains of a solution, containing one part in one hundred thousand of potassium iodide, be treated with 2 drops of nitric and 15 or 20 of sulphuric acid, and afterwards shaken with 15 grains of chloroform, the latter acquires a distinct violet tint. Rabourdin applies his test to the detection of iodine in the several varieties of cod liver oil. For this purpose he incinerates, in an iron spoon, 50 parts of the specimen of oil with 5 of pure potassium hydroxide, dissolved in 15 of water, and exhausts the cinder with the smallest possible quantity of water. The solution is filtered, acidulated with nitric and sulphuric acids, and agitated with 4 parts of chloroform. After a time the chloroform subsides, of a violet color more or less deep according to the proportion of iodine present. Lassaigne considers the starch test more delicate than that of chloroform. For detecting iodine in the iodides of the metals of the alkalies, he considers palladium bichloride as extremely delicate, producing brownish flocks of palladium biniodide. According to Moride, petroleum benzin is a good test for free iodine, which it readily dissolves, forming a solution of a bright-red color, deeper in proportion to the amount of iodine taken up. As petroleum benzin does not dissolve chlorine or bromine, it furnishes the means of separating iodine from these elements. D. S. Price has pointed out the nitrites as exceedingly sensitive tests of iodine combined as an iodide. The suspected liquid is mixed with starch paste, acidulated

with hydrochloric acid, and treated with solution of potassium nitrite. The iodine is set free, and a blue color appears, more or less deep, according to the proportion of iodine present. By this test, iodine may be detected in an aqueous solution containing only one in 400,000 parts. A similar test had been previously proposed by Grange.

It has been long known that when a mixture of iodine and starch in water is subjected to heat the blue color disappears, and that, if the heat be not too long continued, so as to volatilize the iodine or convert it into hydriodic acid, the color will return on the cooling of the liquid. Various explanations have been given of this curious fact by Personne and others, but the only one that is quite satisfactory is that by Magnes-Lahens, which he supports by experiment, that during the continuance of the heat the particles of starch and iodine separate, to unite again on refrigeration. (*J. P. C.*, 4e sér., iii. 405.)¹

Adulterations.—Iodine is said to be occasionally adulterated with mineral coal, charcoal, plumbago, and black manganese oxide. These are easily detected by their fixed nature, while pure iodine is wholly volatilized by heat. Herberger found native antimony sulphide in one sample, and plumbago in another, and Righini has detected as much as 25 per cent. of calcium chloride. The presence of cyanogen iodide and of water has already been referred to, and the modes of detecting and separating them pointed out. (See page 664.) Besides the test given on page 665, the British Pharmacopœia directs that the official iodine should be soluble in alcohol, ether, and a solution of potassium iodide, and should sublime without residue, and that the part which first comes over should contain no colorless prisms of a pungent odor.

Uses.—Iodine was first employed as a medicine in 1819, by Coindet, Sr., of Geneva. It operates as a general excitant of the vital actions, especially of the absorbent and glandular systems. Its effects are varied by its degree of concentration, state of combination, dose, etc., and hence under different circum-

¹ *Amylum Iodatum*. *U. S.* 1880. *Iodized Starch* (*Amyli Iodidum*, *Iodide of Starch*; *Iodure d'Amidon*, Fr.; *Jodstärke*, G.).—"Starch, ninety-five parts [or four hundred and eighteen grains]; Iodine, five parts [or twenty-two grains]; Distilled Water, a sufficient quantity, to make one hundred parts [or one ounce av.]. Triturate the Iodine with a little Distilled Water; add the Starch gradually, and continue triturating until the compound assumes a uniform blue color, approaching black. Dry it at a temperature not exceeding 40° C. (104° F.), and rub it to a fine powder. Iodide of Starch should be preserved in glass-stoppered vials." *U. S.* This preparation has been highly recommended as free from local irritant properties. Dalton of New York, found that nearly all the animal fluids decompose starch iodide and destroy its blue color. (*Am. J. M. S.*, April, 1856, p. 327.) This result is owing, no doubt, to the alkaline nature of most of the animal fluids, especially those of the duodenum, alkaline iodides being formed at the expense of the starch. The dose is a heaped teaspoonful, given in water gruel, three times a day, and afterwards increased to a tablespoonful. No nicety is necessary in apportioning the dose. In some cases Buchanan has given half-ounce (15.5 Gm.) doses, increased to an ounce (31 Gm.).

stances it may prove corrosive, irritant, or simply alterative. It is absorbed into the circulation, and may be found in all the secretions, but is chiefly eliminated by the kidneys, not, however, uncombined, but in the state of hydriodic acid or an iodide. Cantu detected it not only in the urine and saliva, but also in the sweat, milk, and blood. According to Gleg and Bourcet (*C. R. A. S.*, 130, 1721) it is a normal constituent of the blood.

In an overdose iodine acts as an irritant poison. From four to six grains (0.26 to 0.4 Gm.), in man, cause a sense of constriction in the throat, sickness and pain at the stomach, and at length vomiting and colic. Even in medicinal doses it sometimes causes alarming symptoms, such as fever, restlessness, disturbed sleep, palpitations, excessive thirst, acute pain in the stomach, vomiting and purging, violent cramps, frequent pulse, and, finally, progressive emaciation if the medicine be not laid aside. Such violent symptoms are, however, very rare, but where iodine or potassium iodide is given freely a mild *iodism* is not unfrequent. It is usually characterized by pain or heaviness in the region of the frontal sinuses, with or without coryza; in some instances soreness of the mucous membrane of the mouth and throat, or a mild typhism, is the prominent symptom, or a papular eruption may be the first manifestation of the constitutional action of the remedy. Absorption of the mammae and wasting of the testicles have been reported as caused by the long-continued use of the drug, but such results are extremely rare. Lebert noted that these accidents produced by iodine, with scarcely an exception, were in those cases of goitre in which the remedy acted rapidly in removing the tumor, and believed that the bad effects arose from the too prompt absorption of the abnormal material of the tumor, and not from iodine itself. (*Ann. Thér.*, 1855, 228.) The modern discovery that the active principle of the thyroid body can produce rapid wasting singularly confirms the old observation and theory of Lebert.

Iodine has been principally employed in diseases of the glandular system. It has been used with success in *ascites*, especially when connected with diseased liver. It acts most efficiently immediately after tapping. In *glandular enlargements* and chronic indurations it is often of great service. Coindet discovered its extraordinary power in curing *goitre*,¹ and it

has been used with more or less advantage in enlargements and indurations of the liver, spleen, mammae, testes, and uterus. In hepatic affections of this kind, where mercury has failed or is inadmissible, iodine is our best resource. In chronic diseases of the uterus, with induration and enlargement, and in hard tumors of the cervix and indurated puckering of the edges of the os tincæ, iodine has occasionally effected cures, when administered internally and locally applied. In the form of potassium iodide in *advanced syphilis*, *mercurial cachexia*, and *lead poisoning*, it is one of our best remedies. It is habitually employed in *scaly skin affections* and in *chronic rheumatism*. Coindet first directed attention to its effects in *scrofula*, but Lugol, by numerous trials in the Hôpital Saint-Louis, extending from 1827 to 1831, first established the value of the remedy.

The most eligible form of iodine for internal administration is its solution in water, aided by potassium iodide. (See *Liquor Iodi Compositus*.) The solutions employed by Lugol contained one part of iodine and two parts of potassium iodide, and the doses given by him were equivalent to half a grain (0.032 Gm.) of iodine daily for the first fortnight, three-quarters of a grain (0.048 Gm.) daily for the second and third fortnights, one grain (0.065 Gm.) daily during the fourth and fifth fortnights, and, in some cases, a grain and a quarter (0.081 Gm.) daily for the remainder of the treatment, always largely diluted. The tincture of iodine is not as eligible for internal use.

According to Hutet, one grain of iodine is deprived entirely of taste and odor by one teaspoonful of a strong infusion of coffee. (*P. J.*, Dec. 1870.)

The external employment of iodine may be divided into general and topical. By its use externally it does not create a merely local effect, but, by its absorption, produces its peculiar constitutional impression. The external treatment, when general, consists in the use of the *iodine bath*. This for adults should contain from two to four drachms of iodine, with double that quantity of potassium iodide, dissolved in water, in a wooden bath tub, the proportion of the water being about a gallon for every three grains of iodine employed. The quantity of ingredients for the baths of children is one-third as much as for adults, but dissolved in about the same quantity of water. The quantity of iodine and iodide for a bath having been determined upon, it is best to dissolve them in a small quantity of water (half a pint, for example) before they are added to the water of the bath, as this mode of proceeding facilitates their thorough diffusion. The iodine baths, which may be directed three or four times a week, usually produce a slight rubefacient effect, but occasionally a stronger impression, causing the epidermis to peel off, particularly from the arms and legs. The skin at the same time acquires a deep yellow tinge, which usually disappears between the baths.

¹ Chatin, finding, according to his observations, a great variation in the amount of iodine in the air, water, and soil of different localities, has founded on this supposed fact an explanation of the prevalence of goitre and cretinism in some places and their absence in others. Thus, in certain parts of France, near Paris, which he calls the Paris zone, the amount of iodine thus distributed is comparatively large, and goitre and cretinism are unknown, while in the Alpine valleys, where only one-tenth the amount of iodine is found, these affections are endemic. These conclusions are controverted by Lohmeyer of Göttingen, and Kletizinsky of Vienna, who failed to detect iodine in the air of those cities the inhabitants of which are free from goitre. Nicholas Senn (*J. A. M. A.*, 1905) likewise attributes the freedom of the Esquimaux from similar diseases to the large amount of iodine salts consumed by them.

The topical application of iodine is made by means of several official preparations. (See *Unguentum Iodii* and *Tinctura Iodii*.) Besides these, several others have been employed topically. Lugol's *iodine lotion* consists of from two to four grains of iodine, and double that quantity of potassium iodide, dissolved in a pint of water. It is used as a wash or an injection in serofulous *ophthalmia*, *ozæna*, and *fistulous ulcers*. His *rubefacient iodine solution* is formed by dissolving half an ounce of iodine and an ounce of potassium iodide in six fluidounces of water. This is useful for exciting serofulous ulcers, for touching the eyelids, and as an application to recent serofulous cicatrices, to render them smooth. The rubefacient solution, added to warm water in the proportion of about a fluidrachm to the gallon, makes a convenient local bath for the arms, legs, feet, or hands, and, mixed with linseed meal or some similar substance, it forms a cataplasm useful in certain eruptions, especially where the object is to promote the falling off of scabs. External applications of iodine have been recommended for the removal even of internal plastic exudations, as to the side, for example, in protracted pleurisy. The rubefacient preparation of iodine at present most commonly employed is the tincture. (See *Tinctura Iodii*.) The preparation called *iodine paint* is a tincture twice as strong as the official tincture, and is made by dissolving a drachm of iodine and half a drachm of potassium iodide in a fluidounce of alcohol, and allowing the mixture to stand in a glass-stoppered bottle until solution is effected. It is applied with a glass or a camel's hair brush, in one or more coatings, according to the degree of effect desired. Iodine paint is used as a counter-irritant, with advantage, in almost all forms of deep-seated chronic inflammation. When thus used, it must be borne in mind that the iodine acts also by being absorbed. Another valuable application of it is for the removal of *nævi*. Lugol's *caustic iodine solution* is made of iodine and potassium iodide, each, an ounce, dissolved in two fluidounces of water. This is used to destroy soft and fungous granulations, and has been employed with decided benefit in *lupus*.

The *Strong Solution of Iodine* of the British Pharmacopœia¹ is intermediate in strength between the two solutions last mentioned. (See *Liquor Iodii Fortis*, Br.) Another caustic solution of iodine, under the name of *iodized glycerin*, is made by dissolving one part of potassium iodide in two parts of glycerin, and adding the solution to one part of iodine, which it completely dissolves. Max Richter of Vienna, to whom belongs the credit of having introduced into practice the solution of iodine in glycerin, found this caustic particularly useful in *lupus*, non-vascular *goitre*, and serofulous and constitutional syphilitic *ulcers*. The solution is applied by means of a hair-pencil to the diseased surface, which must then be covered with gutta-percha paper, fixed at the edges by

strips of adhesive plaster, in order to prevent the evaporation of the iodine. The application produces burning pain, which rarely lasts for more than two hours. The dressing is removed in twenty-four hours, and pledgets dipped in cold water applied. This iodine caustic is too strong for ordinary local use. A weaker solution is recommended by Szukits, formed of one part of iodine to five parts of glycerin, for application to the neck, female breast, abdomen etc. After four or five paintings it causes excoriation, which requires its discontinuance and the use of cold applications.¹ A mode of applying iodine locally has been suggested by R. Greenhalgh of London, which consists in thoroughly impregnating raw cotton with a solution in glycerin of potassium iodide and of iodine, in the proportion of two ounces of the former and one ounce of the latter to eight ounces of the menstruum, and then drying the "*iodized cotton*." It is intended for application to the cervix or os uteri, which is effected through a speculum. (*L. L.*, May 26, 1866, p. 582.) Méhu's method of making iodized cotton is as follows. Finely divided iodine (5 to 10 parts) is sprinkled between layers of loose cotton (100 parts) introduced

¹*Iodized Oil*.—The following is the original process of Personne. Five parts of iodine are mixed with a thousand parts of almond oil, and the mixture is subjected to a jet of steam, until decolorized. The same operation is repeated with five additional parts of iodine. The oil is then washed with a weak alkaline solution, to remove the hydriodic acid developed in the process. By this mode of proceeding it may be presumed that the iodine is intimately united with the oil, along with which it would find an easy entrance into the system, and that, while about half of the iodine is lost as hydriodic acid, the remainder takes the place of the hydrogen eliminated from the oil. In 1851 the French Academy appointed Gulbourn, Soubeiran, Gibert, and Ricord to report upon the therapeutic value of a definite combination of iodine and oil. The reporter (Gulbourn) approved of Personne's process, and Gibert and Ricord reported favorably of the therapeutic effects of the preparation. Personne's iodized oil differs little in appearance and taste from almond oil, and is easily taken alone or in emulsion. The dose is two fluidounces (60 Cc.) daily, which may be increased to three fluidounces (90 Cc.) or more. (*Am. J. M. S.*, xliii. 502.)

Berthé and Lepage have objected to Personne's iodized oil, that it is of variable iodine strength, and that it is liable to become rancid, in consequence of the use of steam in its preparation. Berthé makes an iodized oil which he alleges to be free from these objections, by heating to about 176° F. five parts of iodine with a thousand parts of almond oil, in a water bath, until decoloration has taken place. The resulting oil is colorless, perfectly transparent, without odor or rancidity, not acted on by starch, and of a constant composition. To shorten the time in preparing the oil, Lepage dissolves the iodine in three times its weight of ether, before adding it to the oil, and briskly shakes the mixture for eight or ten minutes. The preparation is then heated in a water bath, to decolorize it and drive off the ether. Hugoumenq objects to this process, for if the oil be completely deprived of the odor of ether, the heating must be continued for several hours. He also objects to any process which requires the continued application of heat, as rendering the oil liable to become quickly rancid. His plan is to rub up the iodine, for five or six minutes, in a porcelain mortar, with a small portion of the oil, and then gradually to add the remainder. A red limpid liquor is obtained, which may be completely decolorized by exposure for fifteen minutes to the sun's rays. Iodized oil, thus prepared, has the odor and taste of almond oil, is not more liable to become rancid than the pure oil, and is free from hydriodic acid. (*J. P. C.*, Mars, 1856.)

into a tall glass vessel, and the latter placed horizontally on a water or sand bath. As soon as vapors of iodine are seen to rise, and the air has been expelled from the vessel, the latter is tightly stoppered. On continuing to apply a moderate and uniform heat, the iodine vapors penetrate the cotton, and color it yellow. After about two hours, the cotton will have assumed the color of burnt coffee, and the operation is finished. Cotton iodized in other ways, as by immersion in concentrated solutions of iodine in ether or carbon disulphide, retains merely traces of iodine. (*N. R.*, April, 1867.)

Iodine is used by injection into various cavities. It has been employed in this way for the cure or relief of *hydrocephalus*, *pleuritic effusion*, *hydropericardium*, *ascites*, *ovarian dropsy*, *hernia*, *hydrocele*, *spina bifida*, *dropsy of the joints*, *large cystic bronchocele*, and *chronic abscesses*. The discussion of the indications for the use of the injections in these cases, and of the precautions and the methods to be adopted, belongs rather to treatises upon the practice of medicine and surgery than to a work like the present. To such treatises, therefore, the reader is referred.

Enemata containing iodine have been used by several practitioners, in the *chronic dysentery* and *diarrhæa* of both adults and children, with decided benefit, a prominent effect being the relief of tenesmus. They are supposed to act locally on ulcers in the colon and rectum, and generally by absorption. The injection should be made of Lugol's solution, one to ten fluidrachms in one or two quarts of water. It should be preceded by an emollient enema to empty the intestine, and should be repeated once or twice daily, gradually increasing its strength. If the pain is severe, a laudanum injection will bring immediate relief.

Iodine, in the state of vapor, has been employed by inhalation, and the experiments as yet tried have been in the treatment chiefly of *phthisis* and *chronic bronchitis*. Although very extraordinary results were claimed for the method, yet it has entirely failed to fulfil expectations, and is at present very rarely practised. For details as to methods, the reader is referred to the 14th edition of the *U. S. D.*¹

¹ Barrère has proposed the use, for inhalations, of *iodized camphor*, which is to be taken like snuff. This is prepared by putting powdered camphor in a snuff-box, with a hundredth part in bulk of iodine, contained in a muslin bag. In the course of a few hours the substances, by occasional shaking, unite, forming a powder resembling iodine in color. The difficulty in practising ordinary iodine inhalation depends chiefly on the irritation caused by the vapor, which excites cough and fatigues the patient. According to Barrère, this inconvenience is avoided by the use of the iodized camphor. A pinch of it produces sneezing and some smarting in the nostrils, but when the vapor reaches the lungs it causes a refreshing sensation, which induces the patient to draw a long and deep breath. (*Ann. Thér.*, 1855, p. 232.) Hutet recommends the inhalation of hydrochloric ether in affections of the lungs.

Brailnard employs the vapor of iodine, with great advantage, in the treatment of *indolent ulcers*, first dressing the ulcer with simple cerate spread on lint, then applying over this several layers of lint in which from one to four grains of iodine have been folded, and covering the whole with oiled silk and

Iodine or an iodide should not be given in solution with an alkaloid, as it forms insoluble compounds, and in Philadelphia death has been produced by the strychnine iodide which had crystallized out of a mixture; the patient taking in the last dose in the bottle the precipitated strychnine salt. It has even been suggested by R. F. Fairthorne (*A. J. P.*, 1856) and H. W. Fuller (*L. L.*, March 21, 1868, p. 373) as an antidote to alkaloids, but the insoluble compounds of these substances would by no means be inert in the stomach.

In cases of poisoning by iodine, the stomach must be evacuated, and drinks administered containing an amylaceous substance, such as flour, starch, or arrow-root.

The term *ipecacuanha*, derived from the language of the aborigines of Brazil, has been applied to various emetic roots of South American origin.² The botanical character of the ipecac plant of commerce was long unknown. Piso and Margraf, who were the first to treat of this medicine, in their work on the Natural History of Brazil, published at Amsterdam in 1648, described in general terms two plants,—one producing a whitish root, distinguished by the name of white ipecac, the other a brown root, which answers in their description precisely to the official drug. But their account was not sufficiently definite to enable botanists to decide upon the character of the plants. The medicine was generally thought to be derived from a species of *Viola*, which Linnæus des-

tin foil, secured by a bandage, so as to prevent the escape of the iodine, which is vaporized by the heat of the body. (*Chicago Med. Journ.*, Jan. 1860.)
² Weddell states that the word *ipecacuanha* is nowhere in Brazil used to designate the *Cephaelis*, which is generally called *poayá*. (*J. P. C.*, 3e sér., xvi. 34.)

ignated as *V. Ipecacuanha*. Opinion afterwards turned in favor of a plant sent to Linnæus by Mutis from Colombia, as affording the ipecac of that country and of Peru. This was described in the *Supplementum* of the younger Linnæus, 1781, under the name of *Psychotria emetica*, and was long erroneously considered as the source of the true ipecac. Gomez of Lisbon, was the first who accurately described and figured the genuine plant, which he had seen in Brazil, and specimens of which he took with him to Portugal, but Brotero, professor of botany at Coimbra, with whom he had left specimens, having drawn up a description and inserted it with a figure in the Linnæan Transactions without acknowledgment, enjoyed for a time the credit due to his countryman. In the paper of Brotero (1802) the plant is named *Callicocca ipecacuanha*, but the term *Callicocca*, having been applied by Schreber (1789), without sufficient reason, to a genus already named, the name of *Cephaëlis*, Swartz (1788) has been largely used. According to Engler and Prantl, the principal synonyms of the ipecac plant are, besides the official botanical names, *Cephaëlis Ipecacuanha*, Willd., *Psychotria Ipecacuanha*, Müll.-Arg., and *Uragoga Ipecacuanha*, Baill. 150 species of the genus *Uragoga*, according to Engler and Prantl, are to be found in the tropics, of which 100 grow in Brazil. The genus is divided into 4 sections, of which the *Euragoga* (*Cephaëlis*) comprises 73 species, most of which are found in Brazil.

In recognizing *Cephaëlis acuminata*, Karsten, the U. S. Pharmacopœia has followed a very uncertain lead. This species was originally described in literature in Karsten's *Deutsche Flora*, published in 1883, and the only characters given are "leaves elliptical, pointed, stipules separated often almost to their base into a subulate fringe," and that the bark of the root is not separated cylindrically as in the older ipecac, is not uniform in constitution, but formed of radially arranged, vertically directed, parenchymatous cells separated by radii from the inner bark (bast-cells). The differences between elliptical and pointed, and oblong ovate and pointed, are very slight. The leaves of the Brazilian ipecac appear to vary very much in their outlines. Further, Karsten himself states that the stipules of the true ipecac plant are furnished with a subulate fringe of the length or longer than their full surface, so that the difference between the stipules of the alleged species is very slight. Again, the characteristics drawn from the structure of the root do not seem to us of specific value. Carthagena ipecac of the American market does not have the structure spoken of by Karsten, but agrees entirely with ordinary ipecac. Finally, the description by Karsten of *C. acuminata* indicates that he has probably never seen a flowering specimen of the plant. Humboldt, who was evidently familiar with the Colombian plant in its native woods, perceived no difference between it and

the Brazilian form, and the highest botanical authorities do not acknowledge Karsten's species, as *C. acuminata*, though characterized as long ago as 1883, is not in the Index Kewensis nor in Engler and Prantl. The matter is one of some practical importance from the fact that at one time the United States custom authorities objected to the entry of Carthagena ipecac on the ground that it was not ipecac at all, but an adulterant, and gave way largely because it was affirmed that it was the product of *Cephaëlis Ipecacuanha*.

Cephaëlis Ipecacuanha, Richard, *Hist. Ipecac.* p. 21, t. i.; Martius, *Spec. Mat. Med. Brazil*, t. i. p. 4; *Curtis's Bot. Mag.*, N. S., vol. xvii. pl. 4083, 1844.—*Callicocca Ipecacuanha*, Brotero, *Linn. Trans.* vi. 137.—This is a small shrubby plant, with a root from four to six inches long, about as thick as a goose quill, marked with annular rugæ, simple or somewhat branched, descending obliquely into the ground, and here and there sending forth slender fibrils. The stem is two or three feet long, but, being partly under ground, and often procumbent at the base, usually rises less than a foot in height. It is slender; in the lower portion leafless, smooth, brown or ash-colored, and knotted, with radicles frequently proceeding from the knots; near the summit, pubescent, green, and furnished with leaves seldom exceeding six in number. These are opposite, petiolate, oblong-obovate, acute, entire, from three to four inches long, from one to two broad, obscurely green and somewhat rough on their upper surface, pale, downy, and veined on the under. At the insertion of each pair of leaves are deciduous stipules, embracing the stem, membranous at the base, and separated above into numerous bristle-like divisions. The flowers are very small, white, and collected to the number of eight, twelve, or more, each accompanied with a green bract, into a semi-globular head, supported upon a round, solitary, axillary foot-stalk, and embraced by a monophyllous involucre, deeply divided into four, sometimes five or six, obovate, pointed segments. The fruit is an ovate, obtuse berry, which is at first purple, but becomes almost black when ripe, and contains two small plano-convex seeds.¹

The ipecac plant of Brazil flourishes in moist, thick, and shady woods, being most abundant within the limits of the eighth and twentieth degrees of south latitude. It flowers in January and February, and ripens its fruit in May. The root is active in all seasons, but, as it has to be dried rapidly, collection during the rainy season is relaxed. The native collector, or *poayero*, seizes all the stems of a clump, loosens them by a zigzag motion, and then, thrusting a pointed stick under the roots, tears up the

¹*Cephaëlis tomentosa*, of Trinidad, has been studied by Francis Ransom, who finds that it contains emetine, but in too small quantity for commercial purposes. For description of the root, etc., see *P. J.*, xix. p. 258.

whole mass. The roots, freed from dirt by shaking, are then dried. The amount gathered daily varies from 8 to 30 pounds, according to skill and locality. Extirpation does not take place, because, as shown by the Edinburgh gardeners McNab and Lindsay, a very small fragment of the root, or even a petiole of a leaf, will rapidly produce a new plant. Weddell, indeed, many years since, stated that the remains of the root, often purposely left in the ground, serve the purpose of propagation, each fragment giving rise to a new plant. Ipecac of commerce comes chiefly from the interior province of Matto-Grosso, upon the upper waters of the Paraguay (from which in some years as much as 450,000 kilos are shipped), although some is said to be gathered near Philadelphia north of Rio Janeiro. The chief places of export are Rio Janeiro, Bahia, and Pernambuco. It is brought to the United States in large bags or bales.¹

¹ UNOFFICIAL VARIETIES OF IPECAC.—From time to time there have been imported into Europe various drugs stated to be ipecac, but differing from the official drug. Of these the most important are White Ipecac; the Larger Striated Ipecac of Planchon (*J. P. C. Déc.* 1872); and the Lesser Striated Ipecac of Planchon.

White Ipecac. Amylaceous Ipecac. *Undulated Ipecac.* *Larger Undulated Ipecac.* *Ipecac of Carthagena.*—The origin of this variety of ipecac was attributed by Martius to species of *Richardsonia* (*Richardia* of Linnaeus), especially *R. scabra*, *R. brazilensis* of Gomez, and *R. emetica*, but an authentic specimen of the plant, received from Colombia, was found by Hanbury to resemble very closely the official ipecac plant, and H. Baillon has described the source of white ipecac as a new species of *Psychotria* or *Uragoga*, under the specific name of *granatensis*, syn. *Psychotria emetica*, Mutis (not Vell.); the plant is probably merely a variety of the official species. White ipecac occurs in fragments from 5 to 8 millimeters in diameter, cylindrical, marked with rings which are but little pronounced and often wanting. Its color is whitish gray, sometimes verging towards reddish or yellowish. When broken it shows a very thick, hard, horny bark, with a dry, whitish or grayish-brown or black, farinaceous surface, displaying in the full sunlight little shining points. It is chiefly distinguished from the official drug by its greater size, its gray external color, the feebleness of its undulation, and the comparative smallness of its woody centre. It is inodorous and insipid, and contains, according to Pelletier, a very large proportion of starch, with only 6 per cent. of impure emetine and 2 per cent. of fatty matter. Richard found three and one-half parts of emetine in the hundred; Palangé found 3 per cent., but in 1860 Lefort obtained from a specimen nearly as much emetine as occurs in the official roots. White ipecac evidently varies in its strength, and, as it sometimes is mixed with genuine roots, it would seem probable that it is the root of the official plant modified by climatic influence, or is composed of inferior roots obtained from very old specimens of the official plants. This probability is confirmed by the microscopic characters, the structure of the root being very closely similar to that of the official drug.

Larger Striated Ipecac (Planchon). *Violet Striated Ipecac.* *Ipecac of St. Martha.* *Ipecac of Carthagena.* *Striated Elastic Ipecac* (Attfeld).—This variety of ipecac is generally acknowledged to be the product of *Psychotria emetica*, Mutis, not Vell., growing in the deep forests of Colombia. It is a small shrub, with a stem twelve or eighteen inches high, simple, erect, round, slightly pubescent, and furnished with opposite, oblong-lanceolate, pointed leaves, narrowed at their base into a short petiole, and accompanied with pointed stipules. The flowers are small, white, and supported in small clusters towards the end of an axillary peduncle. The drug occurs in rather long fragments, sometimes 9 or 10 centimeters (3 or 4 inches), with a thickness of from 5 to 9 millimeters ($\frac{3}{8}$ to $\frac{1}{2}$ of an inch). The pieces are for the most part almost straight, sometimes sinuous, more rarely tortuous. At distant intervals they are

In 1866 the cultivation of ipecac was introduced into India by King, but it was not until twenty years later (1886), when it was found

marked by contractions, or circular furrows. Their whole surface is largely striated longitudinally. To their upper part are often attached one or more remaining portions of the stem, distinguished from the root by their much smoother surface. Their color is a grayish brown, tending sometimes to reddish brown. Like other ipecacs, they have an outer cortical and a central ligneous portion. The former is soft, so that it may even be penetrated by the nail. It has a horny aspect, and a variable color, passing from whitish, by shades of rose, violaceous, and blackish violet. The central part is yellowish of the root, and becomes still greater when this is immersed in water. The central part is yellowish white. The root has little odor, and a taste scarcely nauseous, sometimes flat, and often sweetish. As to the microscopic characters, the most striking are probably the total absence of the starch granules, and the relatively very small diameter of the vessels in the central part. Chemically this variety is characterized by the presence of a principle capable of reducing the cupro-potassic reagent. It is so abundant in the cortical part that a simple digestion in water gives a liquid with strong reducing powers, but without deviating action on polarized light. The larger striated ipecac comes from Colombia.

Lesser Striated Ipecac (Planchon). *Ipecac des Côtes d'Or* (Pelletier). *Black Ipecac.* *Black Striated Ipecac.* *Striated Brittle Ipecac* (Attfeld). *False Ipecac* (Holmes).—It is not known from what plant this is obtained. It occurs in very short fragments, 2 or 3 centimeters at most long, and 2 or 3 millimeters in thickness; some nearly cylindrical, others narrowly fusiform; others again formed of roundish or pyriform segments, somewhat thicker than the preceding, placed end to end. The color is generally of a gray brown, darker than that of the other kind. The longitudinal striae are fine, and regular on the transverse section. The cortical portion is as it were horny, and its consistence firmer than in the larger kind; the central part is yellowish, and under the microscope exhibits numerous pores. The ligneous centre is at once distinguished by the size of its vessels, which give it a porous appearance. The presence of the starch granules is another of the distinguishing characters of this variety. It contains a larger proportion of emetine than the preceding, yielding, according to the analysis of Pelletier, 9 per cent.

According to Martius, different species of *Ionidium* (*Viola*, Linn.) also produce what is called *white ipecac*. The roots of all the species of *Ionidium* possess emetic or purgative properties. The root of *I. Ipecacuanha* is described by Guibourt as being six or seven inches long, as thick as a quill, somewhat tortuous, and exhibiting at the point of flexion semicircular fissures, which give it some resemblance to the root of the Cephaëlis. It is often bifurcated at both extremities, and terminates at the top in a great number of small ligneous stalks. It is wrinkled longitudinally, and of a light yellowish-gray color. The bark is thin, and the interior ligneous portion very thick. The root has little taste or odor. According to Pelletier, 100 parts contain 5 of an emetic substance, 35 of gum, 1 of nitrogenous matter, and 37 of lignin. (*Histoire abrégée des Drogues simples*, 1. 514.)

The root of a species of *Ionidium* growing in Quito has attracted some attention as a remedy in elephantiasis, under the South American name of *cutchunchilli*. The plant received from Bancroft the name of *I. Morucueti*; but Hooker found the specimen received from Bancroft to be the *I. parviflorum* of Ventenat. Lindley thinks a specimen he received under the same name from Quito to be the *I. microphyllum* of Humboldt. If useful in elephantiasis, it is so probably by its emeto-purgative action. (See *A. J. P.* vii. 186.)

Under the name of *East Indian Ipecac* there has appeared in the London markets a root of a pale pinkish-brown color, tapering rapidly from the base to the apex, and having annulations much closer than in the true ipecac. It is especially distinguished from the latter root by being evidently monocotyledonous—that is, without the central woody column—the vascular bundles appearing under a pocket lens as a more or less irregular ring of brownish dots. R. A. Cripp obtained from it a minute quantity of an alkaloidal substance, certainly distinct from the alkaloids of ipecac (*P. J.*, lv.). Ranwez and Campon have also described a false ipecac derived from a monocotyledonous plant, *Cryptocoryne spiralis*. (*Ann. Pharm.*, l.)

that ipecac flourished in the Straits Settlements equally as well as in Brazil, that its cultivation became successful.

Properties.—Genuine ipecac is in pieces two or three lines thick, variously bent and contorted, simple or branched, consisting of an interior slender, light straw-colored, ligneous cord, with a thick, brittle, brownish, finely wrinkled, cortical covering, which presents on its surface a succession of circular, unequal, prominent rings or rugæ, separated by very narrow fissures, frequently extending nearly down to the central fibre. This appearance of the surface has given rise to the term *annelé*, or *annulated*, by which the true ipecac is designated by French pharmacists. The cortex is hard, horny, and semi-transparent, breaks with a resinous fracture, and easily separates from the tougher ligneous fibre, which possesses the medicinal virtues of the root in a much inferior degree. On microscopic examination the very thick bark is seen to be formed of uniform parenchymatous cells, without traces of the medullary rays, which are very distinct in the woody central cylinder. Attached to the root is frequently a smoother and more slender portion, which is the base of the stem, and should be separated before pulverization. Pereira has met, in the English market, with distinct bales composed of these fragments of stems, with occasionally portions of the root attached. Much stress has been laid upon the color of the external surface of the ipecac root, and diversity in this respect has even led to the formation of distinct varieties. Thus, the epidermis is sometimes deep brown or even blackish, sometimes reddish brown or reddish gray, and sometimes light gray or ash-colored; hence the varieties of ipecac root which were formerly recognized, the *brown*, *red* and *gray*. It is now known that the color of the root varies according to the circumstances of growth and soil, so that coloration as the basis of classification has been abandoned, and the ipecacs of commerce are divided according to their geographical sources, into the *Brazilian* or *Rio Ipecac*, the *Carthagen* or *Colombia Ipecac*, and the *Johore* or *Indian Ipecac*; of these, the two varieties which are recognized by the U. S. Pharmacopœia are described as follows: "*Rio Ipecac*.—In pieces of irregular length, rarely exceeding 25 Cm.; stem-portion 2 to 3 Mm. thick, light gray-brown, cylindrical and smoothish; root-portion usually red-brown, occasionally blackish-brown, rarely gray-brown, 3 to 6 Mm. thick, curved and sharply flexuous, nearly free from rootlets, occasionally branched, closely annulated with thickened, incomplete rings, and usually exhibiting transverse fissures, with vertical sides, through the bark; fracture short, the very thick, easily separable bark whitish, usually resinous, the thin, tough wood yellowish-white, without vessels; odor very slight, peculiar, the dust sternutatory; taste bitter and nauseous, somewhat acid. *Carthagen Ipecac*.—Similar to

Rio Ipecac, but about one-half thicker, dull gray externally, with thinner, merging annulæ, and the fractured surface of the bark gray." U. S.

Carthagen ipecac is usually to be distinguished from the Brazilian by its lighter color and the fact that many of its roots are scarcely at all annulated, and some are even smooth. On the other hand, in most specimens of Carthagen ipecac which we have examined, some of the roots could not be distinguished from those of the Brazilian variety. The cultivation of ipecac, which was introduced into India by the British Government, has especially succeeded in the neighborhood of Johore (Straits Settlement). On account of the great local demands in India, only a small amount of this ipecac comes into general commerce, and very little of it reaches the United States. *Johore* or *Indian ipecac* is especially characterized by the excellent appearance, regularity and large size of the roots, which are deeply annulated, somewhat light in color, and having to a marked degree the general physical and microscopical characteristics of the Brazilian root. According to Ransom, Paul and Cownley, and to Umney and Swinton, it is very rich in alkaloids, and, like the Brazilian root, has for its dominant alkaloid, emetine. (See *P. J.*, vol. 63, 69, 70.) Many years ago there was imported from Carácas into the United States a large gray ipecac with badly marked rings. This variety disappeared for a time, but is probably the *Colombian* or *Carthagen Ipecac* of modern commerce.

According to the researches of A. R. L. Dohme (*A. J. P.*, 1895), the stems adhering to the ipecac roots contain from fifteen to twenty per cent. less of the alkaloids than do the roots themselves. Moreover, it appears to be established that the portions of the stem distinct from the root contain much less of the alkaloids than does the base of the stem, so that the Pharmacopœia very properly directs that not more than 7 Cm. of the stems shall be allowed. The bark of ipecac root should make eighty per cent. of the whole. When the bark in either variety of ipecac is opaque, with a dull amylaceous aspect, the root is less active. As the woody part is nearly inert, and much more difficult of pulverization than the cortical, it often happens that, when the root is powdered, the portion last remaining in the mortar possesses scarcely any emetic power, and care should be taken to provide against any defect from this cause.¹ The German Pharmacopœia

¹For elaborately illustrated articles upon the microscopy of ipecac and its adulterations, see Henry G. Greenish, *P. J.*, 1895, 685, and Albert Schneider, *Am. Drug.*, 1897. According to Greenish, the distinctive characteristics of the powder of either Brazilian or Carthagen ipecac are: (a) the form and size of the starch grains; (b) the absence of vessels, presence of perforated tracheoides; (c) the acicular rapheids; to these may be added (d) the emetine reaction with chlorine. The stem may in either case be distinguished from the root (in powder) by the presence (a) of sclerenchymatous cells; (b) of lignified cells of the pith; (c) of spiral vessels.

provides for the rejection of the last fourth of the powder. The color of the powder is a light grayish fawn.¹ Microscopically, ipecac root is composed of a suberous layer of thick-walled cells on the outside, next, of parenchymatous tissue, five or six strata of irregular four-sided cells, which from without inward at first increase and then diminish in size. Raphides are in small numbers, but all the cells are gorged with starch granules, which are mostly compound, being composed of from two to eight or even more grains, which are muller-shaped, with one or two flat surfaces. The hilum is usually distinct, with two or three radiating crevices, sometimes scarcely apparent. The individual starch granules are 1.5 micromillimeters or less in diameter, the compound granules range from 7 to 19 micromillimeters in their longest diameter. The existence of swollen granules indicates the use of artificial heat in drying the roots. The liber is composed of

remedies has become one of importance. Paul and Cownley (*A. J. P.*, 1901), as the result of an exhaustive study, found that the two ipecacs do not differ materially in the total amount of alkaloid contained, but that whereas in the Brazilian root emetine is the dominant alkaloid, in the Colombian root cephaeline predominates, and that therefore the two roots cannot be considered as therapeutically identical. This work of Paul and Cownley has been confirmed by Carl Lowin (*A. J. P.*, 11), so that it would appear to be settled that in general terms Rio ipecac contains 1.5 per cent. of emetine and 0.5 of cephaeline; Carthagena contains 0.9 of emetine and 1.2 of cephaeline. The practical accuracy of these researches, however, has been challenged by the large dealers in the products of ipecac. In 1903, as the result of twenty assays of different lots of each drug, Caesar and Loretz of Halle report the results given in the following table.

	Total Alkaloids.	Emetine.	Cephaeline.	Ash.
Rio (Mato Grosso Root)	2.73	1.98	0.50	8.34
Rio (Bahia Root)	2.19	1.36	0.63	3.21
Indian from Johore	2.45	1.46	0.62	2.93
Carthagena	2.75	1.47	1.39	6.02

much smaller cells, is irregular in thickness, and is rather full of starch. The cambium layer is formed of three or four series of colorless cells. The wood has its medullary rays very slightly marked, and contains only a few vessels, which are situated near the centre of the root.

According to A. G. C. Patterson, neither by studying the yield of ash nor the microscopical characters of a powder, is it possible to determine whether it is derived from Brazilian or Colombian roots. Ipecac has little odor in the aggregate state, but when powdered has a peculiar nauseous odor, which in some persons excites violent sneezing, in others dyspnoea resembling an attack of asthma. The taste is bitter, acrid, and very nauseous. Water and alcohol extract its virtues, which are injured by decoction.

Ipecac depends for its medicinal properties upon the presence of the alkaloids *emetine* and *cephaeline*; there is also in it *ipecacuanhic acid*, discovered by Erwin Willigk, and shown by Reich (*A. Pharm.*, [2], 113, 208), to be a glucoside, having the formula $C_{14}H_{15}O_7$. (See *A. J. P.*, xxiii. 352.) Ipecac roots differ not only in the total percentage of alkaloidal contents but also in the proportion of the alkaloids, and the question whether Rio and Carthagena ipecac ought to be considered as interchangeable

A. R. L. Dohme, of the firm of Sharp and Dohme of Baltimore, states that these analyses are in accord with their laboratory records, and the probabilities seem to be that neither of the varieties of ipecac root are consistent in the proportionate percentages of alkaloids, this proportion varying with the accidents of growth and surroundings of the individual plant.

Formerly Brazilian ipecac commanded in the American market a higher price than did the Carthagena variety. At this time, 1905, the Carthagena ipecac is from ten to fifteen cents a pound higher than the Brazilian, indicating that in some way it especially recommends itself to the manufacturing pharmacists. Paul and Cownley (*A. J. P.*, 1895, 256) give to the amorphous alkaloid the name *emetine*, and find it to have the formula $C_{15}H_{22}NO_2$ and the melting point $60^\circ C$. The crystalline alkaloid accompanying it in the Brazilian ipecac they call *cephaeline*, and give it the formula $C_{14}H_{20}NO_2$ and the melting point $102^\circ C$. According to this, emetine is *methyl-cephaeline*. The third alkaloid found by them, which in a later article (*A. J. P.*, 1901, pp. 87, 107) they name *psychotrine*, melts at $138^\circ C$, and apparently has a much higher molecular weight than emetine or cephaeline. This alkaloid and its salts are rapidly decomposed on exposure to light; in this respect differing from emetine and cephaeline, both of which are unaffected by light. It is a crystalline alkaloid which separates from ether in prisms of a lemon-yellow color.

Various processes have been published for the isolation of emetine, and these will be found in previous editions of this work (see *U. S. D.*, 17th ed., 752), but according to the researches

¹The Carthagena ipecac can usually be distinguished by the great size of its starch grains, although there are some Carthagena roots that contain small granules of starch.

²Attempts have been made to adulterate powdered ipecac with the powder of almonds, but the fraud is readily detected by forming a paste with a little water and putting it into a hot place for half an hour, when, if the ipecac is pure, only its own odor will be perceived, but, if adulterated, a decided odor of almonds will be noticed. (*J. P. C.*, Juin, 1874, 479.)

above quoted, none yield pure emetine. The results of Paul and Cownley's researches (1899) are summarized below. W. G. Whiffen patented in Germany in 1898 a process for making emetine, basing it on the separation of emetine hydrobromide from extract of ipecac; cephaeline hydrobromide crystallizes with great difficulty, while emetine hydrobromide is easily crystallized and separated. (*C. D.*, 1898, 694.)

Emetine ($C_{15}H_{22}NO_2$), discovered by Pelletier in 1867, is an amorphous white powder; melting point 60°C . It forms crystalline salts with the halogens and nitric acid; dissolves readily in chloroform, ether, benzene, or alcohol, its alcoholic solution giving no coloration with ferric chloride. It is insoluble in solutions of caustic or carbonated alkalis, but easily dissolved in diluted acetic acid. Glacial acetic acid dissolves emetine without effecting substitution. From the acetic acid solution, potassium hydroxide precipitates a white, flocculent precipitate, insoluble in excess, but readily soluble in ether.

Emetine hydrobromide ($C_{15}H_{22}NO_2 \cdot \text{HBr} \cdot 2\text{H}_2\text{O}$), which is suggested as the most convenient salt of emetine for medicinal use, is permanent, occurring in white, silky needles, readily soluble in water, difficultly soluble in absolute alcohol or chloroform.

Cephaeline ($C_{14}H_{20}NO_2$) is crystalline, occurring in white, silky needles, becoming yellow on exposure to light; melting point, 96.9°C ., when crystallized from ether, or 102°C ., when the crystallization is effected by adding ammonia to a salt in the presence of ether. It dissolves easily in ether, benzene, chloroform, or alcohol. Ferric chloride added in small quantity to an alcoholic solution produces a dark reddish-brown coloration; this is believed to be due to the presence of phenol-hydroxyl. Cephaeline dissolves easily in solution of potassium hydroxide, and is not extracted by ether; it is easily soluble in acetic acid, and is reprecipitated by the cautious addition of potassium hydroxide as a white precipitate which is soluble in excess of the alkali. It is upon the peculiar behavior of cephaeline with caustic alkali and ether that the separation of cephaeline and emetine depends. Hesse assigns to emetine the formula $\text{C}_{30}\text{H}_{42}\text{N}_2\text{O}_4$, and to cephaeline $\text{C}_{28}\text{H}_{38}\text{N}_2\text{O}_4$.

Ipecacuanhic Acid.—According to the researches of Tokuye Kimura, ipecacuanhic acid occurs as a brown, hygroscopic, amorphous mass, freely soluble in warm water and alcohol but very slightly soluble in cold water or ether, insoluble in chloroform, having the formula $\text{C}_{17}\text{H}_{26}\text{O}_{10}$ or a multiple of the same. As a glucoside it is allied to the saponin acids but has no hæmolytic action and does not form soapy solutions. Its most characteristic reaction is that its solution strikes with ferric chloride a green alizarin tint, which, by the addition of ammonia or saturated baryta water, changes to violet or blackish, with the final separation of a blackish-brown precipitate. On the addition to the

discolored solution of diluted hydrochloric acid the green color returns. According to the experiments of Kimura, ipecacuanhic acid is readily absorbed but is possessed of feeble physiological activity and is not germicidal, so that the value of ipecac in dysentery can scarcely depend upon its presence. (*A. I. P.*, 1903, 1.)

The U. S. Pharmacopœia (8th Rev.) introduced an assay process for determining the value of ipecac, this became necessary because of the variations in the quality of ipecac found in commerce and the difficulty of accurately judging of its quality by either macroscopical or microscopical characteristics.

Assay. U. S. (8th Rev.).—"Ipecac, in No. 80 powder, fifteen grammes, Ether, Chloroform, Ammonia Water, Distilled Water, Normal Sulphuric Acid V.S., Tenth-normal Sulphuric Acid V.S., Fiftieth-normal Potassium Hydroxide V.S., Hematoxylin T.S., a sufficient quantity. Introduce the Ipecac into an Erlenmeyer flask of 250 Cc. capacity, add 115 Cc. of ether and 35 Cc. of chloroform, shake the flask during five minutes, and then add 3 Cc. of ammonia water and again shake the flask at intervals during half an hour. Now add 10 Cc. of distilled water, shake the liquid until the powder collects in masses, and pour off 100 Cc. of the clear ethereal solution into a measuring cylinder. Transfer the latter to a separator, add 10 Cc. of normal sulphuric acid V.S. and 10 Cc. of distilled water. Shake the separator moderately during two minutes, and when the liquids have separated, draw off the lower acid solution into a second separator. Repeat the shaking out of the ether-solution with 3 Cc. of normal sulphuric acid V.S. and 5 Cc. of distilled water, drawing the acid solution into the second separator. Repeat the shaking out again, using 10 Cc. of distilled water, and add the aqueous solution to the second separator. Reject the ether in the first separator, introduce a small piece of red litmus paper into the second separator, add enough ammonia water to render the liquid alkaline, and 25 Cc. of ether, and then shake the separator vigorously during one minute; draw off the alkaline aqueous liquid into another separator, and transfer the ether-solution to a flask. Add 20 Cc. of ether to the alkaline liquid in the separator, shake it for one minute, and, having allowed the liquids to separate, draw off the alkaline liquid into the other separator, and transfer the ether-solution to the flask. Again shake out the alkaline liquid with 10 Cc. of ether, and, when the fluids have separated, reject the alkaline liquid and add the ether-solution to the liquid in the flask. Distil the ether from the flask with the aid of a water-bath, and dissolve the alkaloidal residue in 12 Cc. of tenth-normal sulphuric acid V.S., warming it gently on a water-bath if necessary. Then add five drops of hematoxylin T.S. and titrate with fiftieth-normal potassium hydroxide V.S. Divide the number of cubic centimeters of fiftieth-nor-

mal potassium hydroxide V.S. used, by 5, subtract the quotient from 12 (the 12 Cc. of tenth-normal sulphuric acid V.S. taken), and multiply the remainder by 0.0238, and this product by 10, which will give the percentage of alkaloids in the Ipecac." *U. S.*

Flückiger (*Ph. Ztg.*, 1886, p. 30) gives a process for assaying ipecac, which consists in exhausting 10 to 15 grammes of the drug in very fine powder with boiling chloroform to which a drop of solution of ammonia has been added; the extraction is continued until the chloroform passing through shows no sign of alkaloid when treated with acidulated water. Upon distilling off the chloroform, the emetine is left in a very pure condition, and may be dried at 100° C. and weighed, or perhaps more conveniently titrated with Mayer's reagent. He found the average quantity of emetine in ipecac root not to exceed 1 per cent. (*P. J.*, 1886, 643.) H. W. Jones approves of this method, and modifies it by treating the residue from the chloroformic solution with water and diluted sulphuric acid, filtering, and recovering the alkaloid by means of chloroform and ammonia. (*P. J.*, 1886, p. 277.) For other methods see a paper by A. B. Lyons, *A. J. P.*, 1885, pp. 531, 542; also *Lyon's Assay of Drugs*, 1899, 181, 187.

Uses.—Ipecac is in large doses emetic, in smaller doses, diaphoretic and expectorant, and in still smaller, stimulant to the stomach, exciting appetite and facilitating digestion. In quantities not quite sufficient to cause vomiting, it produces nausea, and frequently acts on the bowels. As an emetic it is mild, but tolerably certain, and free from corrosive or narcotic properties, and especially fitted for use when no other effect than emptying the stomach is desired. It was employed as an emetic by the natives of Brazil when that country was first settled by the Portuguese, but, though described in the work of Pison, it was not known in Europe until 1672, and did not come into use until some years afterwards. John Helvetius, grandfather of the famous author of that name, having been associated with a merchant who had imported a large quantity of ipecac into Paris, employed it as a secret remedy, and with so much success in dysentery and other bowel affections that general attention was drawn to it, and the fortunate physician received from Louis XIV. a large sum of money and public honors on the condition that he should make it public. Ipecac appears to have a stimulant effect upon the general glandular structures in the digestive tract, which renders it of great value in *tropical dysenteries*. As a nauseating remedy it is used in *croup*, and as a diaphoretic combined with opium, in numerous diseases. (See *Pulvis Ipecacuanhæ et Opii*.) Its expectorant properties render it useful in the early stages of *acute bronchitis*. It has been given, also, with supposed advantage, in very minute doses, in *dyspepsia*, and in chronic disease of the gastro-intestinal mucous membrane, and as an anti-emetic. Ipecac is most

conveniently administered, as an emetic, in the form of powder suspended in water, and if it fails to act in 15 to 20 minutes the dose should be repeated; this may be done several times with entire safety. Both cephaeline and emetine are powerful emetics, and in overdoses violent poisons. They have been found in the lower animals to be powerful depressants of the motor side of the spinal cord and to kill by a centric paralytic asphyxia. They are also depressant to the heart itself. On account of the violence of their action they are very rarely used in practical medicine. According to several writers the dose of impure emetine is about a grain (0.065 Gm.), of the pure not more than an eighth of a grain (0.008 Gm.), repeated at proper intervals until it causes vomiting. An ointment made with one part of powdered ipecac, one of olive oil, and two of lard, rubbed once or twice a day for a few minutes upon the skin, produces a copious and very permanent eruption, but is at present only very rarely employed as a counter-irritant.

Dose, emetic, twenty to thirty grains (1.3 to 2 Gm.); nauseating, two grains (0.13 Gm.); diaphoretic, one grain (0.065 Gm.); stomachic, one-fourth to one-half grain (0.016 to 0.032 Gm.).

JALAPA. U. S., Br.

JALAP

(jā-lā'pā)

"The dried tuberous root of *Exogonium Purga* (Wenderoth) Benth (Fam. *Convolvulaceæ*), yielding, when assayed by the process given below, not less than 8 percent. of total resin, but not more than 1.5 percent. of resin soluble in ether." *U. S.* "The dried tubercles of *Ipomœa Purga, Hayne.*" *Br.*

Radix Jalapæ, Radix Ipomœarum; Jalap Tubéreux ou *officinal, Fr. Cod.*; *Tubera Jalapæ, P. G.*; *Jalape, Jalapenknoien, Jalapenwurz, G.*; *Gialappa, Schiappa, It.*; *Jalapa (Kaiz de), Sp.*

The precise botanical origin of jalap remained long unknown. It was at first ascribed by Linnæus to a *Mirabilis*, and afterwards to a new species of *Convolvulus*, to which he gave the name of *C. Jalapa*. The correctness of the latter reference was generally admitted, and, as the *Ipomœa macrorrhiza* of Michaux, growing in Florida and Georgia, was believed to be identical with the *C. Jalapa* of Linnæus, it was

thought that this valuable drug, which had been obtained exclusively from Mexico, might be collected within the limits of the United States; but the error of this opinion was soon demonstrated. John R. Coxe of Philadelphia, received living roots of jalap from Mexico in 1827, and succeeded in producing a perfect flowering plant, of which a description, by Nuttall, was published in the *Am. J. M. S.* for January, 1830. The same plant has since been cultivated in various parts of Europe,¹ and has been introduced into the Neilgherry Hills of India, where it grows vigorously. J. H. Balfour (*Curtis's Bot. Mag.*, Feb. 1847) maintains that the plant belongs to the genus *Exogonium* of Choisy, as defined in De Candolle's *Prodromus*, being distinguished from *Ipomœa* by its exerted stamens. Benthams and Hooker, however, do not acknowledge the validity of the various genera into which *Ipomœa* has been broken up by Choisy (*Genera Plantarum*, ii.). Engler and Prantl have restored the genus *Exogonium* [*E. Purga* (Wender.), Benth.] for the plant yielding the root called jalap.

Exogonium Purga, Balfour, *Curtis's Bot. Mag.*, 3d ser., vol. iii. tab. 4280; B. & T. 186. *Ipomœa Jalapa*, Nuttall; Carson, *Illustr. of Med. Bot.*, ii. 13, pl. 61. *Ipomœa Purga*, Hayne, *Darstell. und Beschreib.*, etc., xii. 33 and 34; Lindley, *Flor. Med.*, 396.—The root of this plant is a roundish somewhat pear-shaped tuber, externally blackish, internally white, with long fibres proceeding from its lower part, as well as from the upper rootstalks. A tuber produced by Coxe was, in its third year, between two and three inches in diameter. The stem is round, smooth, much disposed to twist, and rises to a considerable height upon neighboring objects, about which it twines. The leaves are heart-shaped, entire, smooth, pointed, deeply sinuated at the base, prominently veined on their under surface, and supported upon long footstalks. The lower leaves are nearly hastate, or with diverging angular points. The flowers, which are large and of a lilac-purple color, stand upon peduncles about as long as the petioles. Each peduncle supports two or, more rarely, three flowers. The calyx is without bracts, five-leaved, obtuse, with two of the divisions external. The corolla is funnel-form. The stamens are five in number, with oblong, white, somewhat exerted anthers. The stigma is simple and capitate.

The jalap plant is a native of Mexico, where it is dug during the whole year, and usually dried over the hearths of the Indian huts. It derives its name from the city of Jalapa, in the state of Vera Cruz, in the neighborhood of which it grows, at the height of about 6000 feet above the ocean. The drug is brought from the port of Vera Cruz in bags containing

usually between 100 and 200 pounds.¹ The jalap plant is now successfully cultivated in the government cinchona plantations in India. Analyses of the Indian tubers show that when grown on fresh soil they contain from 16 to 17 per cent. of resin, and that by manuring the percentage is notably increased, even to 22 per cent. For an account of the cultivation of jalap in Madras, see *Am. Drug.*, 1896, 127.

Properties.—The tuber comes either whole, or divided longitudinally into two parts, or in transverse circular slices. The entire tubers are irregularly roundish, or ovate and pointed, or pear-shaped, usually much smaller than the fist, and the larger ones marked with circular or vertical incisions, made to facilitate their drying. The root is preferred in this state, as it is less apt to be defective and is more easily distinguished from the adulterations than when sliced. A much larger proportion comes entire than formerly, indicating a greater scarcity of the older roots, which it is necessary to slice in order to dry them properly. The tuber is heavy, compact, hard, brittle, with a shining undulated fracture, not fibrous, but exhibiting irregular dark concentric lines, and, when examined under the microscope, numerous compound starch grains, clustered crystals of calcium oxalate, and cells containing resin (resinous points when viewed under a low magnifying power). Externally the tuber is brown and wrinkled, internally of a grayish color, diversified by concentric darker circles, in which the matter is denser and harder than in the intervening spaces. Jalap is always kept by pharmacists in the state of powder, which is of a yellowish-gray color, and when inhaled irritates the nostrils and throat, and provokes sneezing and coughing. The odor of the root, when cut or broken, is heavy, sweetish, and rather nauseous; the taste is sweetish, somewhat acrid, and disagreeable. Jalap is officially described as follows: "Napiform, pyriform or oblong, 3 to 8 Cm. long and 1 to 5 Cm. in diameter, the large roots often incised, more or less wrinkled, dark brown, with lighter colored spots, and short transverse ridges; hard, compact, internally dark brown, with numerous concentric circles composed of small resin cells; fracture resinous, lustrous, not fibrous; odor slight, but peculiar, smoky and sweetish; taste sweetish and acrid." *U. S.* It yields its active properties partly to water, partly to alcohol, and completely to diluted alcohol.

Buchner and Herberger supposed that they had discovered a basic substance, which they called *jalapin*. G. A. Kayser found that the resin of jalap previously discovered by Cadet de Gassicourt consists of two portions, one of which, amounting to seven parts out of ten, is hard and insoluble in ether, the other is soft and soluble in that menstruum. The hard resin

¹ The jalap grows freely in the south of England, but the season is too short for the production of seed by it, although the root has yielded 11.97 per cent. of resin. (*P. J.*, Feb. 1869.)

¹ The root of *I. pandurata* (L.), Meyer, *Man Root, Man of the Earth*, of this country, is sometimes met with in American commerce. C. Manz found a resin in it. (*A. J. P.*, 1881, 384.)

he named *rhodeoretin*, and found to be identical with the jalapin of Buchner and Herberger. By reaction with the alkalis it is converted into an acid, called *rhodeoretinic acid*. Rhodeoretin is slightly soluble in water, freely so in alcohol, and insoluble in ether, chloroform, or benzene, and the alcoholic solution is precipitated both by ether and water. It is dissolved by solutions of the alkalis, more quickly if heated, and is not precipitated by acids, having become soluble by conversion into the acid above referred to. It purges violently in the dose of three or four grains, and is supposed to be the active principle of jalap. Mayer confirmed and extended the observations of Kayser. He gave the name of *convolvulin* to Kayser's rhodeoretin, and stated its formula as $C_{31}H_{50}O_{16}$. This substance is colorless when pure, dissolving easily in ammonia water, and is not reprecipitated by acids, because of its conversion into *convolvulinic acid*, which is a

of volatile *methylethyl-acetic acid*, $C_5H_{10}O_2$, one molecule of *purginic acid*, $C_{25}H_{48}O_{12}$, and one molecule of *convolvulinic acid*, $C_{45}H_{80}O_{28}$. (See also *A. Pharm.* 1901, 373.) This latter is amorphous, yielding a white hygroscopic powder soluble in water and alcohol, insoluble in ether; strong sulphuric acid colors it red or brown-red; by the action of acids one molecule of convolvulinic acid yields five molecules of a glucose and one molecule of *convolvulinolic acid*, $C_{15}H_{30}O_6$, which is insoluble in water, melts at $51.5^\circ C.$, is not colored by sulphuric acid, and is isomeric with jalapinolic acid and scammonolic acid, both of which melt at from 63° to $64^\circ C.$ A. F. Stevenson (*N. R.*, 1879, 359) has studied the two resins found in jalap, and furnishes a tabular statement of the differences between the soft resin jalapin and the hard resin convolvulin, which is given in the following table. For the method of obtaining the resin of jalap pure, see *Resina Jalapæ*.

1. Action of solvents.			2. Reactions with Oxidizing Agents on convolvulin and jalapin dissolved in concentrated sulphuric acid.		
Solvent.	Jalapin.	Convolvulin.	Agent.	Jalapin.	Convolvulin.
Chloroform.	Readily soluble.	Slightly soluble.	Potassium dichromate.	Produces odor of rancid butter and reddish brown color.	Produces odor of rancid butter and olive-green color.
Ether.	Very soluble.	Insoluble.	Potassium permanganate.	Same reactions.	Same reactions.
Petrol. naphtha.	Slightly soluble.	Insoluble.	Potassium nitrate.	Same reactions, but not so strong.	Same reactions.
Oil of turpentine.	Slightly soluble.	Insoluble.	Potassium chlorate.	Same reactions, but not so strong.	Same reactions.
Benzene.	Slightly soluble.	Insoluble.	Manganese dioxide.	Same odor, and color dark green.	Same odor, and color rose-pink.
Carbon disulph.	Easily soluble.	Insoluble.			
Water.	Slightly soluble.	Slightly soluble.			
Hydrochloric acid.	Slightly soluble.	Readily soluble.			
Sulphuric acid.	Very soluble, with production of maroon color changing to black.	Readily soluble, with production of bright red coloration.			
Potassium hydroxide.	Easily soluble.	Easily soluble, with production of odor of whisky when heated.			
Ammonia water.	Readily soluble, more so than convolvulin.	Slightly soluble.			

hydroxide of the glucoside convolvulin. This, on being treated with nitric acid, yields *sebacic acid*. Convolvulin possesses in a high degree the purgative properties of jalap. Mayer obtained from *Ipomœa orizabensis* a resin which he called *jalapin*, which was afterwards shown by Keller to be identical with the resin of scammony. Mayer's jalapin differs from convolvulin in being soluble in ether. The formula of jalapin, according to Samuelson, is $C_{34}H_{56}O_{18}$. Poleek (*A. J. P.*, 1892, p. 465) continued the investigation of the jalapin from *I. orizabensis*, and confirmed the identity of it with scammonin, giving it the formula $C_{34}H_{56}O_{18}$. He suggested that the name of jalapin, which is misleading, should be replaced by *orizabin*. A. Kromer (*Ph. Z. R.*, 1894, Nos. 1-7) also made a study of convolvulin. He finds it to be lævogyrate, and gives it the formula $C_{31}H_{50}O_{17}$, which was later changed (*Die Glykoside*, Van Rijn, 1900, p. 391), and is now given by Hoehnel as $C_{54}H_{96}O_{27}$, which is deduced from its analysis and decomposition products; alkalis decompose it into one molecule

Jalap is apt to be attacked by worms, which, however, are said to devour the amylaceous or softer parts, and to leave the resin, so that the worm eaten drug is more powerfully purgative than that which is sound. Thus, out of 397 parts of the former, Henry obtained 72 parts of resin, while from an equal quantity of the latter he procured only 48 parts. Hence, worm eaten jalap should be employed for obtaining the resin, but should not be pulverized, as it would afford a powder of more than the proper strength. The drug is also liable to various adulterations, or fraudulent substitutions, which, however, can usually be detected without difficulty. Those which have attracted particular attention are mentioned in the note below.¹

¹ *Tampico Jalap* (*Purga de Sierra Gorda, Mexican*.)—This drug closely resembles in appearance, odor, and taste the true jalap, but the tubers are somewhat smaller, more elongated and shrivelled. According to Ambrose Andouard, it is the *jalap digité majeur* of Gubourt. Through the efforts of Daniel Hanbury of London, aided by two Prussian officials in Mexico, Hugo Finck, vice-consul at Cordova, and

The percentage of resin is determined by the following assay process:

Assay. U. S. (8th Rev.).—"Jalap, in No. 60 powder, ten grammes; Ether, Alcohol, Chloro-

E. Bonecke, consul-general at Mexico, the origin of the drug was traced to the state of Guanajuato, where it grows along the Sierra Gorda, near San Luis de la Paz. In this place it is purchased from the Indians, and conveyed by mules to Tampico, where it enters into commerce. Through the agency of the same gentlemen, Hanbury, after some failures, succeeded in obtaining a living tuber, from which he raised a flourishing plant that proved to be an undescribed species of the genus *Ipomoea*, differing from *I. Purga* by its bell-shaped corolla and pendulous flower-buds. To it Hanbury gave the name *I. simulans* (A. J. P., July, 1870). H. Spigartius of Königsberg, obtained a resin by preparing a tincture of the Tampico jalap, evaporating, washing, boiling the residue in water, redissolving in alcohol, and decolorizing by charcoal. He gave it the name of *tampicin*. Its physical properties are similar to those of the jalap resin. It is brittle, tasteless, inodorous, insoluble in water, soluble in ether and alcohol, and in solution has a feeble acid reaction. By strong alkalies it is changed into a soluble acid which Spigartius calls *tampicoic acid*. By the action of diluted sulphuric, nitric, or hydrochloric acid, it is converted, slowly if cold, but rapidly with heat, into a peculiar acid called *tampicoic*, with sugar. For the mode of preparing these acids, and their properties, the reader is referred to an article in *N. R.*, July, 1871, p. 50. The melting point of *tampicin* is 130°C .; its formula is $\text{C}_{20}\text{H}_{34}\text{O}_{14}$. The percentage of it yielded by the drug varies from a minimum of 10 per cent. (Hanbury) to a maximum of 15 per cent. (Unney). Andouard states that it is purgative.

According to Herlant, even in powder it is easy to detect the presence of the root of *Mirabilis Jalapa*, which is sometimes used as an adulterant to jalap, by the presence of acicular raphides (calcium oxalate). Tampico jalap can also be distinguished from the Vera Cruz variety by the microscope. In Tampico jalap the starch is arranged in little compact masses in the cell, while in Vera Cruz jalap the starch occurs in grains irregularly united, or isolated and much larger than those of the Tampico variety. The agglomerated masses of resin in the Tampico jalap are smaller than those in the Vera Cruz jalap.

Mexicoan.—Jalap is said to be sometimes adulterated with *Bryonia* root, but no instance of the kind has come under our notice, and the two drugs are so widely different that the fraud should be instantly detected. (See *Bryonia*, PART II.) It is probable, however, that the adulteration which has been considered as *bryonia* root is the *mechoacan*, which in Europe is sometimes called American bryonia and was formerly erroneously supposed to be derived from a species of *Bryonia*. Mechacan is a product of Mexico, which was taken to Europe even before the introduction of jalap. The plant producing it has been conjectured to be *I. pandurata* (L.), Meyer, of Michaux, which is believed to grow in Mexico near Vera Cruz, as well as in our Southern States, and the root of which is said to weigh, when of full size, from fifty to sixty pounds, and, according to Baldwin, has little or no purgative power. But this origin is quite uncertain; Guibourt states that the mechacan of Europe is the product of *Asclepias contrajerva*. (J. P. C., iv., 1866.) Mechacan is in circular slices, or fragments of various shapes, white and farinaceous within, and, as found in the European markets, generally destitute of bark, of which, however, portions of a yellowish color sometimes continue to adhere. The larger slices are sometimes marked with faint concentric striae, and upon the exterior surface are brown spots and ligneous points, left by the radicles after removal. (Guibourt.) Though tasteless when first taken into the mouth, it becomes after a time slightly acid. It is very feebly purgative. We have seen flat circular pieces of root, mixed with jalap, altogether answering this description, except that the cortical portion still remained, between which and the starchy parenchyma there was an evident line of division.

Orizaba Root. Male Jalap. Light, Woody, or Fusiform Jalap. Jalap Stalks. *Purgo Macho* (Mexican).—This is the product of a plant named by M. Ledanols *Convolvulus orizabensis*, now known as *I. orizabensis* (Pell.). Ledan., from the city of Orizaba, in the neighborhood of which it grows abundantly. A description of it was first published in this country by D. B. Smith, in a paper in A. J. P. (II. 22). For an account of the plant the

form, Distilled Water, each, a sufficient quantity. Insert a pledget of purified cotton in the neck of a funnel or small glass percolator, introduce the powdered Jalap and pour ether upon it,

reader is referred to the same journal (x. 224). The recent root is large, spindle-shaped, sometimes twenty inches in length, branched at its lower extremity, yellow on its outer surface, and white and milky within. The drug, as described by Guibourt, is in circular pieces, two or three inches in diameter, or in longer and more slender sections. As we have seen it, the shape of the pieces is often such as to indicate that the root has been sliced transversely and each circular slice divided vertically into quarters. The horizontal cut surface is dark from exposure, unequal from the greater shrinking in desiccation of some parts than others, and presents the extremities of numerous fibres, which are often concentrically arranged, and run in the longitudinal direction of the root. Internally the color is grayish, and the texture, though much less compact than that of jalap, is sometimes almost ligneous. The taste is at first slight, but after a time becomes somewhat acid and nauseous. It has cathartic properties similar to those of the true jalap, but feebler, requiring to be given in a dose of from thirty to sixty grains in order to operate effectively. (J. P. C., xlv. 166.) The resin of *C. orizabensis*, which has been unfortunately named *jalapin* by Mayer, is according to that chemist, changed by boiling with baryta water into an acid called *jalapic acid*, and both jalapin and jalapic acid are glucosides, being resolved by boiling with dilute acid into glucose, and a peculiar substance which he designates as *jalapinol*. (See J. P. C., 3e sér., xxix. 123.) It differs from jalap resin in consisting of only one principle, which is entirely soluble in ether. But both resins are distinguished from all others by being gradually dissolved in concentrated sulphuric acid, and deposited again after some hours in a soft state. (*Chem. Gaz.*, No. 53; from *Ann. Ch. Ph.*) Its formula is $\text{C}_{20}\text{H}_{34}\text{O}_{16}$. Samuelson (*In. Dis.*, Breslau, 1883), who has made a study of it, considers it to be the anhydride of the dibasic jalapic acid, $\text{C}_{20}\text{H}_{38}\text{O}_{18} - 2\text{H}_2\text{O} = \text{C}_{20}\text{H}_{34}\text{O}_{16}$. Potassium permanganate oxidizes jalapinol to jalapinic acid, $\text{C}_{20}\text{H}_{36}\text{O}_{18}$. Hanbury and Flückiger obtained 11.8 per cent. of it from the root, and state that it is probably the jalapin of English pharmacy. It is considered by chemists identical with the resin of scammony, and is affirmed to have similar drastic properties. These results were confirmed by Poleck (*loc. cit.*) except that jalapinol could not be obtained.

Rose-scented Jalap. *Overgrown Jalap*.—A false jalap was some years since brought into market, imported from Mexico into New York in considerable quantities, and was offered for sale under the name of *overgrown jalap*. A specimen brought to Philadelphia and examined by a committee of the College of Pharmacy presented the following characters. It was in light, entire or vertically sliced tubers, of different forms and magnitudes, spindle-shaped, ovate and kidney-form, some as much as six inches long and three thick, others much smaller, externally somewhat wrinkled, with broad, flattish, light-brown ridges, and shallow darker furrows, internally grayish white, with distant darker concentric circles, sometimes uniformly amylaceous, of a dull rough fracture, a loose texture, a slight, peculiar, and sweetish odor, and a feeble jalap-like taste. The powder was of a light-gray color, and did not irritate the nostrils or throat during pulverization. The root differed from mechacan by the absence of the marks of rootlets, and from male jalap by the want of a fibrous structure. It yielded by analysis, in 100 parts, 3 of a soft and 4 of a hard and brittle resin, 17 of gummy extract, 28 of starch, and inulin, 10 of gum and albumen, 23.2 of lignin, and 14.8 of saccharine matter and salts of lime, including loss. In doses of from fifteen to twenty grains it produced no effect on the system. A similar root was described by Guibourt by the name of *rose-scented jalap*. It was taken to France from Mexico, mixed with genuine jalap. It proved as inefficacious as overgrown jalap as a purgative, and probably had the same origin. This spurious drug is probably the product of a *Convolvulus* or *Ipomoea*. (See A. J. P., xiv. 289.)

Two varieties of false jalap, imported into New York, are described by John H. Currie in the *N. Y. J. Pharm.* for Jan. 1852. The first corresponds with the root above described as that of *Convolvulus orizabensis*, or *male jalap*, both in appearance and in the character of its resinous ingredient. The second is a tuberous root, resembling, in shape, color, and size, the butternut, or fruit of *Juglans cinerea*, being

keeping the funnel or percolator well covered, until 50 Cc. of percolate have been obtained. Transfer the percolate to a tared beaker, evaporate the ether by means of a water-bath, and weigh the residue. The weight multiplied by ten will give the percentage of ether-soluble resin in the Jalap. Continue the percolation of the powder (which has been exhausted by the ether) with alcohol, until 100 Cc. of percolate have been obtained. Measure 20 Cc. of this percolate into a separator, add 20 Cc. of chloroform, mix the liquids and then add 20 Cc. of distilled water, and shake the separator thoroughly for one minute. When the liquids have completely separated, draw off the chloroform into a tared beaker, wash the separator with 5 Cc. of chloroform, and add the washings to the tared beaker. Evaporate the chloroform with the aid of a water-bath, and then dry the residue to a constant weight. This weight multiplied by fifty will give the percentage of resin insoluble in ether in the Jalap. Add to this the percentage of ether-soluble resin already determined, and the result will be the percentage of total resin contained in the Jalap." *U. S.*

The average percentage of resin in Jalap has of late years distinctly lessened; indeed this fact has received official recognition. The *U. S. P.* 1890 required 12 per cent., and the French Codex 1884, 16 to 18 per cent. Much of the commercial jalap is far below the lowered official standard, and this appears to be due, not, as believed by Flückiger, to the extraction of the resin from the roots in Mexico, but to the fact that the wild tubers are collected indiscriminately from November to March; the cultivators of India are very careless in their methods. The lowness of the *U. S. P.* standard (8 per cent.) is to be regretted, especially as the *Br. Ph.* requires 11 per cent., but it is probably necessary, practically, to meet the commercial conditions. The German Pharmacopœia of 1900, however, requires 9 per cent. (For various analyses of commercial Jalap see *U. S. D.*, 18th ed., also *J. P.*, lxxii. p. 152.)

black or nearly so externally, dull over most of the surface but glossy in spots, with deep longitudinal incisions, internally yellow or yellowish white, with a horny fracture, and upon the transversely cut surface marked with sparse dots, as if from delicate fibres. It contains no resin, and appears to be inert.

In the *J. P. O.* (Dec. 1863, p. 477, and March, 1864, p. 212) three other tubers are described by Guibourt which have been offered in the market for jalap,—one named *false jalap of New Orleans*, because imported into France from that city, the second *digitate jalap* (*jalap digité*), from the arrangement of its component tubers, and the third *radiated false jalap* (*faua-jalap rayonné*), from the stellate appearance of the cut surface. These jalaps do not closely resemble in physical properties the true root.

Another false jalap, some tubers of which were exhibited to Procter by Mexicans, who stated that they were produced on grounds in Mexico belonging to them, is described by him in *A. J. P.* (Sept. 1868, p. 389), to which the reader is referred for a particular account of it. Though differing in shape and interior structure from genuine jalap, they had precisely the odor of that product, and a similar wrinkled appearance and mottled brown color externally, and were probably derived from a plant either of the same genus as jalap or of one closely related to it.

"Jalap, when assayed by the process described under '*Jalapæ Resinæ*,' should yield not less than 9 nor more than 11 per cent. of resin having the properties of the official resin." *Br.* For Alcock's method of assay see *A. J. P.*, 1892, 533.¹

Jalap should be rejected when it is light, of a whitish color internally, of a dull fracture, spongy, or friable. Powders of calomel and jalap, taken on long voyages to southern climates, are said, when brought back, to have become consolidated, and so far chemically altered as plainly to exhibit globules of mercury. This change is ascribed by Schacht and Wackenroder to a fungous growth. (*A. Pharm.*, xxxix. 239.) The best criterion of good quality in jalap is the proportion of its resinous constituent, and all specimens intended for use in the powdered form, or in any liquid preparation, should be rejected if they contain less than 8 per cent. of resin.

Uses.—Jalap is an active cathartic, operating briskly and sometimes painfully upon the bowels, and producing copious watery stools. The aqueous extract purges moderately, without much griping, and is said to increase the flow of urine. The portion not taken up by water gripes severely. The aqueous extract obtained from jalap, previously exhausted by rectified spirit, is said to have no cathartic effect, but to operate upon the kidneys. (Duncan.) The alcoholic extract, usually called resin of jalap, purges actively, and often produces severe griping. From these facts it would appear that the virtues of this cathartic do not depend exclusively upon any one principle. Experiments, however, by John C. Long of Philadelphia, seem to show that the gummy extract, which he took in the quantity of a drachm without any effect, is inert, while the soft resin, or that soluble in ether, which was thought to have but feeble power, if any, acted powerfully as a hydragogue cathartic in a dose of three grains. (*A. J. P.*, 1861, p. 489.) Jalap was introduced into Europe in the latter part of the sixteenth or the beginning of the seventeenth century, and at one time ranked among the purgative medicines most extensively employed. It is applicable to most cases in which an active cathartic is required, and from its hydragogue powers is especially adapted to the treatment of dropsy. It is generally given in connection with other medicines, which assist or qualify its operation. In dropsical complaints it is usually combined with potassium bitartrate. With calomel it forms a cathartic com-

¹ The question as to possible substitutes for the official species is also growing in importance. Flückiger pointed out that the seeds of the *Ipomœa hederacea* (*Kaladana seeds*) yield 8 per cent. of resin identical with that obtained from *Ipomœa Purga*, and the additions to the British Pharmacopœia now recognize *Kaladana* and its resin. Shimoyama of Tokio, has shown that jalap resin can be obtained from the *Ipomœa triloba* (*Pharbitis triloba*) of Japan. M. K. Hyrano confirms this, and states that the seeds of the plant have long been used in Japan, under the name of "*kengashi*." (For details, and method of extracting the resin, see *P. J.*, Oct. 1888.)

pound which has long been highly popular, in the United States, in *bilious fever* and other complaints attended with *congestion of the liver* or portal circle. In overdoses it may produce dangerous hypercatharsis. It is said to purge when applied to a wound. Jalapin when taken internally is probably absorbed, but as yet its presence has never been detected in the urine, and it remains uncertain whether it is eliminated or destroyed. Müller (*In. Dis.*, Dorpat, 1885) found traces of it in the blood, and even in the heart, lungs, and spleen, of cats poisoned with it.

The dose of jalap, in powder, is from ten to twenty grains (0.65 to 1.3 Gm.); of the extract, from four to eight grains (0.26 to 0.5 Gm.); of the resin, from two to four grains (0.13 to 0.26 Gm.). The dose of calomel and jalap is five grains (0.32 Gm.) of each; of potassium bitartrate and jalap, two drachms (7.7 Gm.) of the former and from ten to fifteen grains (0.65 to 1.0 Gm.) of the latter.¹

KAOLINUM. U. S., Br.

KAOLIN

(kā-ō-lī'nūm)

"A native aluminum silicate, consisting chiefly of the pure silicate [$\text{H}_2\text{Al}_2\text{Si}_2\text{O}_5 + \text{H}_2\text{O} = 257.12$], powdered and freed from gritty particles by elutriation." U. S. "A native aluminum silicate, powdered, and freed from gritty particles by elutriation." Br.

Terra porcellanea; Porcelain Clay, Fuller's Earth, Bolus Alba; Terre à porcelaine, Fr.; Porcellanerde, Porcellanthon, G.

This substance was introduced into the U. S. P. (8th Rev.) for the purpose of forming the basis of the new official preparation *Cataplasma Kaolini* (see page 306).

Kaolin, $\text{Al}_2(\text{SiO}_3)_2 + \text{Al}_2\text{O}(\text{OH})_2$, occurs in abundant deposits as a decomposition product of felspar; the latter is a double silicate of aluminum and alkali, and in its weathering, the alkali is gradually eliminated. A pure kaolin contains approximately 47 per cent. of silica, 40 per cent. of alumina, and 13 per cent. of water.

Pure kaolin is almost infusible, but the presence of impurities, notably undecomposed

felspar, increases its fusibility greatly. On the other hand, fire clays which are infusible are kaolins containing a considerable amount of free silica.

Large deposits of kaolin have been recently opened in Florida. It is now used extensively for clarifying oils, such as lard and cotton seed oils and mineral lubricating oils. It is officially described as "a soft, white, or yellowish-white powder, or in lumps, having an earthy or clay-like taste, insoluble in water, and in cold dilute solutions of the acids and alkali hydroxides. When moistened with water, Kaolin assumes a darker color and develops a marked clay-like odor. If 1 Gm. of Kaolin be mixed with 10 Cc. of water and 5 Cc. of sulphuric acid in a porcelain dish, no effervescence should occur, and if the mixture be evaporated until the excess of water has been removed, and further heated until dense white fumes of sulphuric acid appear, then after cooling and adding 20 Cc. of water, boiling for a few minutes and filtering, there should remain on the filter a gray insoluble residue of *impure silica*. If to one-half of the filtrate ammonia water be added, a gelatinous precipitate of *aluminum hydroxide*, insoluble in excess, should be obtained. If to the remaining half of the filtrate, sodium hydroxide T.S. be added, it should yield a gelatinous precipitate which is almost or completely soluble in an excess of the reagent. If 2 Gm. of Kaolin be rubbed in a mortar with 10 Cc. of water, the mixture should not acquire more than a slight reddish tint on the addition of 0.5 Gm. of sodium salicylate (absence of more than traces of iron). If Kaolin be ignited at a red heat, it should leave not less than 85 per cent. of non-volatile residue." U. S. The British Pharmacopœia describes it as "a soft whitish powder insoluble in water or in diluted acids. The product of its fusion with alkalis, digested in water, and neutralized with *hydrochloric acid*, affords the reactions characteristic of aluminium, a gelatinous precipitate of silica being formed." Br.

Uses.—Kaolin is used as an absorbent powder when dusted upon the surface of the body in irritated conditions of the skin. *Cimolite* is a perfumed powder having similar physical properties to kaolin. Kaolin is not easily affected by most chemical reagents, and it forms a good diluent or excipient for silver nitrate, potassium permanganate, or other salts which are decomposed by organic substances.

KINO. U. S., Br.

KINO

(kī'nō)

"The inspissated juice of *Pterocarpus Roxburghii* (Fam. Leguminosæ)." U. S.

¹ The British Addendum recognizes the following preparation:—"Tinctura Jalapæ Composita. Compound Tincture of Jalap. Jalap, in No. 40 powder, 1 oz., 262 grains [Imperial] or 80 grammes; Scammony, in No. 40 powder, 175 grains [Imperial] or 20 grammes; Turpeth, in No. 40 powder, 88 grains [Imperial] or 10 grammes; Alcohol (60 per cent.) a sufficient quantity. Moisten the mixed powders with two fluid ounces [Imp. meas.] or one hundred cubic centimetres of the Alcohol, and complete the percolation process. The resulting Tincture should measure one pint [Imp. meas.] or one thousand cubic centimetres.

Dose, $\frac{1}{2}$ to 1 fluidrachm." Br.

"The juice obtained from incisions made in the trunk of *Pterocarpus Marsupium*, Roxb., evaporated to dryness." Br.

Gummi (s. Resina) Kino; Indian Kino, Malabar Kino; Kino de l'Inde, Fr. Cod.; Kino, G.; Goma quino, Sp.

The term kino was originally applied to a vegetable extract or inspissated juice taken to London from the western coast of Africa, and introduced to the notice of the profession by Fothergill. Vegetable products obtained from various other parts of the world, resembling kino in appearance and properties, afterwards received the same name, and much confusion and uncertainty existed, and in some degree still exist, in relation to the botanical and commercial history of the drug. We shall first consider the general properties of medicines denominated kino, then the several varieties.

Properties.—Kino, as found in commerce, is usually in small, irregular, angular, shining fragments, seldom as large as a pea, of a dark reddish-brown or blackish color, very brittle, easily pulverizable, and affording a reddish powder, much lighter colored than the drug in its aggregate state. It is officially described as in "small, angular, dark red, shining pieces, brittle, in thin layers ruby-red and transparent; inodorous, very astringent, and sweetish, tingeing the saliva deep-red. Soluble in alcohol, nearly insoluble in ether, and slowly soluble in cold water." U. S. If in large masses, it may be reduced without difficulty into these minute fragments. It is without odor, and has a bitter, highly astringent taste, with a somewhat sweetish after-taste. It burns with little flame, and does not soften with heat. It imparts its virtues and a deep red color to water and alcohol, but is nearly insoluble in ether. Cold water forms with it a clear infusion. Boiling water dissolves it more largely, and the saturated decoction becomes turbid on cooling, and deposits a reddish sediment. The tincture is not disturbed by water. When long kept, it often gelatinizes, and loses its astringency. (See *Tinctura Kino*.) Kino undoubtedly consists chiefly of a modification of tannic acid or tannin, which has received the name of *kino-tannic acid*, with extractive, gum, and sometimes probably a little resin, but we need a careful analysis of the different well-ascertained varieties. The aqueous solution is precipitated by gelatin, the soluble salts of iron, silver, lead, and antimony, mercuric chloride, and sulphuric, nitric, and hydrochloric acids. The precipitate with iron is of an olive or greenish-black color. The alkalies favor the solubility of kino in water, but essentially change its nature and destroy its astringency. Both Pharmacopœias require that kino should be almost entirely soluble in alcohol (90 per cent.), but should yield little or nothing to ether; the Br. Ph. also demands that not less than 80 per cent. should be soluble in boiling water.

1. EAST INDIA KINO. *Malabar Kino*.—This is the variety at present probably most used

and most highly esteemed, and the only one recognized by the British and United States Pharmacopœias. Its origin was long unknown. It is now ascertained, through the researches of Pereira, Royle, Wight, and others, to be the product of *Pterocarpus Marsupium*, a lofty tree growing upon the mountains of the Malabar coast of Hindostan. Kino is the juice of the tree extracted through longitudinal incisions in the bark and afterwards dried in the sun. Upon drying it breaks into small fragments, and is put into wooden boxes for exportation. It is collected near Tellicherry, and exported from Bombay. It is sometimes imported into this country directly from the East Indies, but more commonly from London. From a communication in the *Journal of the Asiatic Society of Bengal*, by F. Mason, it appears that kino is also collected in the Tenasserim provinces, in Farther India, and has been exported from Maulmain to Europe. It is produced by a tree called *Pa-douck*, which was supposed to be a species of *Pterocarpus*, although its precise characters were not certainly known. (*A. J. P.*, xxi. 134.) Christison subsequently recognized, in a description of this tree furnished to him by Begbie of Maulmain, the precise characters of *Pterocarpus Marsupium*, so that this kino has the same origin as that from Malabar. *Pterocarpus indicus*, of the Mauritius Islands, where it is known as *sang dragon*, also yields a red kino to commerce.

Macaranga Kino is obtained from *Macaranga Roxburghii*, Wright, of the Deccan peninsula. It occurs in the form of odorless, tasteless tears or irregular masses. The tears have fibrous fractures and when immersed in water yield unravelling fibres giving the appearance of a sea anemone. According to Hooper this kino yields from 6 to 15 per cent. of a peculiar tannin and is closely allied to *Butea kino*, from which it is distinguished by fibrous tears and the fact that it contains so much gum which swells without dissolving in water. (*P. J.*, 66, 616.)

East India kino is in small, angular, glistening fragments, of a uniform consistence, appearing as if formed by the breaking down of larger masses. The larger fragments are opaque and nearly black, but minute splinters are sometimes translucent, and of a deep garnet redness when viewed by transmitted light. This variety of kino is very brittle, readily breaking between the fingers, and easily pulverized, affording a dark reddish powder, a portion of which, resulting from the mutual attrition of the fragments, is often found interspersed among them. When chewed, it softens in the mouth, adheres somewhat to the teeth, and tinges the saliva a blood-red color. In odor, taste, and chemical relations it corresponds with the account already given of kino in general. When kino is boiled in water, the decoction deposits, on cooling, a bright red substance, and a similar deposition takes place when a cold filtered aqueous solution is long exposed with a broad surface to the air. Ac-

cording to Hennig, kino consists of tannic acid with a trace of gallic acid, kinoic acid, pectin, ulmic acid, and inorganic salts, with excess of earthy bases. (See *A. J. P.*, xv. 544.) C. Etti obtained a new constituent, *kinoin*, by extracting kino with ether. He finally adopted the following method as more practicable. One part of gum kino is added to 2 parts of boiling diluted (1 to 5) hydrochloric acid. Kino-red immediately separates as a soft mass, becoming gradually solid on cooling, while the *kinoin*, mixed with a small quantity of kino-red, remains in solution. The solid residue is once more boiled with water, the liquids are united and shaken with ether. The ethereal solution, on evaporation, leaves a crystalline reddish residue, which is dissolved in hot water, on the cooling of which tolerably pure crystals of *kinoin* are obtained. By continued recrystallization they are obtained colorless. Their formula is $C_{14}H_{12}O_6$, and *kino-red* is the anhydride of this:

This kino-red, heated to 160° to 170° C., parts with a molecule of water and yields a lower anhydride, $C_{28}H_{20}O_{10}$. Both anhydrides are precipitated by gelatin, but kinoin itself is not. When heated with hydrochloric acid to 120° to 130° C., kinoin yields methyl chloride, gallic acid, and catechol, and hence probably has the constitution of a *guaiacol* or *methyl-catechol gallate*. Kino contains about 1.5 per cent. of kinoin. (*Ber. d. Chem. Ges.*, N. R., Feb. 1879.) Kremel found Malabar kino, Butea gum, eucalyptus kino, and the kino from *Coccoloba uvifera* to be free from Etti's kinoin, but to contain a body acquiring, like kinoin, a red color with ferric chloride, which proved to be *pyrocatechuic acid*; this was present either alone or mixed with gallic acid. (*A. J. P.*, 1883, 267.) In an examination made by David Hooper of ten varieties of East Indian kino, the proportion of tannic acid was found, after thoroughly drying the kino, to vary from 80 to 97 per cent. of the whole mass. (*Agricultural Ledger of India*, No. 11, 1901.)

2. WEST INDIA OR JAMAICA KINO.—This is believed to be the product of the *Coccoloba uvifera*, L., or *sea-side grape*, a tree twenty feet or more in height, bearing beautiful broad shining leaves, and large bunches of purple berries, to which it owes its vernacular name. It grows in the West Indies and neighboring parts of the continent. The kino is said to be obtained by evaporating a decoction of the wood and bark, which are very astringent. Many years since, a thick reddish-brown liquid was imported into Philadelphia from the West Indies, which, when dried by exposure to the air in shallow vessels or by heat, afforded an extract having all the properties of kino, for which it was sold by the druggists. This has long been exhausted, but some years since, a considerable quantity of West India kino was brought into this market, which may still be found in small quantities in commerce. It was

contained in large gourds, into which it was evidently poured while in a liquid or semi-liquid state, and then allowed to harden. When taken from the gourd it breaks into fragments of various sizes, upon an average about as large as a hazelnut, and having some tendency to the rectangular form. The consistence of these fragments is uniform, their surface smooth and shining, and their color a dark reddish brown approaching to black. They are, however, neither so glistening nor so black as the East India kino. In mass they are quite opaque, but in thin splinters are translucent and of a ruby redness. They are readily broken by the fingers into smaller fragments, are easily pulverized, and yield a dull-reddish powder, considerably lighter colored than that of the former variety. The West India kino is without odor, and has a very astringent, bitterish taste, with a scarcely observable sweetish after-taste. It adheres to the teeth when chewed, though rather less than the East India variety, and colors the saliva red. The solubility of Jamaica kino was very carefully examined by Robert Bridges, who found that cold water dissolved 89 per cent., and ordinary official alcohol 94 per cent. The portion dissolved by alcohol and not by water was probably of a resinous nature, as it appeared to be viscid, and very much impeded the filtration of the aqueous solution. Considering the nature of this substance, the form of kino in which it was found is probably, like that from the East Indies, an inspissated juice. Guibourt, who states that Jamaica kino is but slightly dissolved by cold water, must have operated on a different product.

3. SOUTH AMERICAN KINO. *Caraccas Kino*. In 1839, an astringent extract was described which had recently been introduced into our market, derived from Caraccas, and known by that name to the druggists. Since that period it has come much more extensively into use. It is probably the same as that described by Guibourt, in the last edition of his *History of Drugs*, as the kino of *Colombia*. As imported, this variety of kino is in large masses, some weighing several pounds, covered with thin leaves, or exhibiting marks of leaves upon their unbroken surface, externally very dark, and internally of a deep reddish-brown or dark portwine color. It is opaque in the mass, but translucent in thin splinters, very brittle, and of a fracture always shining, but in some masses wholly rough and irregular, in others rough only in the interior, while the outer portion, for an inch or two in depth, breaks with a rather smooth and uniform surface, like that of the West India kino. This outer portion is easily broken into fine angular fragments, while the interior crumbles quite irregularly. Some of the masses are very impure, containing pieces of bark, wood, leaves, etc.; others are more homogeneous, and almost free from impurities. The masses are broken up by means of a mill so as to resemble East India kino, from which, however, this variety differs in

being more irregular, less sharply angular, more powdery, and less black. On comparing the finer and more angular portions of the masses of this kino with the West India variety, Geo. B. Wood could discover no difference between the two kinds either in color, lustre, taste, or other sensible property. The colors of the powder were also identical. South American kino was found by Bridges to yield 93.5 per cent. to cold water, and 93 per cent. to alcohol; so that, while it has almost the same solubility as Jamaica kino in alcohol, it is somewhat more soluble in cold water. The aqueous solution in this case was not embarrassed by the adhesive matter which impeded the filtration in the former variety, and the want of a minute proportion of resinous matter in the South American kino is the only apparent difference between the two drugs. It is not improbable that they are derived from the same plant, and there is no difficulty in supposing that this may be the *Coccoloba uvifera*, as that tree grows as well upon the continent as in the islands.

4. AFRICAN KINO.—The original kino employed by Fothergill was known to be the product of a tree growing in Senegal, and upon the banks of the Gambia, on the western coast of Africa, but the precise character of the tree was not ascertained until a specimen, sent home by Mungo Park during his last journey, enabled the English botanists to decide that it was the *Pterocarpus erinaceus* of Lamarck and Poiret.¹ The Edinburgh and Dublin Colleges accordingly referred kino in chief to this plant, but, in so doing, overlooked the fact that not one of the varieties now used is brought from Africa. The importation of African kino has long ceased.² In 1896, however, a consignment of African kino reached London. It was exam-

¹ A particular account of *Pterocarpus erinaceus* and its concrete juice, with a figure, by W. F. Daniell, is contained in the *P. J.* for August, 1854 (vol. xiv. p. 55).

² *Butea gum*, which has sometimes been mistaken for African kino, is the concrete juice of the *Butea frondosa*, Roxb., or *Dhak-tree* of Hindostan, and also to some extent of *B. superba*. The juice flows from natural fissures, and from wounds made in the bark of the tree, and quickly hardens. It is in small elongated tears, or irregular angular masses, less in size than a grain of barley, apparently black and opaque, but translucent and of a ruby-red color when examined in small fragments by transmitted light; in some specimens the tears are much paler than described, and of a very beautiful ruby tint. Many of the tears have small portions of bark adhering to them. They are very brittle, and readily pulverizable, yielding a reddish powder. They are very astringent to the taste, do not adhere to the teeth when chewed, and tinge the saliva red. The relations of this product to water, alcohol, and other chemical reagents are nearly the same as those of ordinary kino. When freed from impurities, consisting of from 15 to 25 per cent. of wood, bark, sand, etc., it contains, according to E. Solly, 73.26 per cent. of tannin, 5.05 of soluble extractive, and 21.67 of gum and other soluble substances. It is used in the arts in India, and might undoubtedly be employed as kino in medicine. It is, however, very seldom imported into England, and never, at present, into this country. Pereira found a quantity in an old drug store in London, and sent a portion to Guibourt, from which that writer drew up his description of African kino. It is possible that the kino which formerly reached us, full of small pieces of wood, bark, etc., may have been the *Butea gum*. For a description of the seeds of *B. frondosa* from which *Bengal Kino* is derived, see *Ph. Rev.*, 1896, 232.

ined by E. M. Holmes, who stated that it was evidently yielded by *P. erinaceus*. (*C. D.*, 1896, 226.) It is said to be still used by the Portuguese of Angola, under the name of *Sangue de Drago*. As described by Fothergill, the African kino, for which he proposed the name of *gummi rubrum astringens Gambiense*, was in lumps of about the size of those of gum Senegal or dragon's blood, and so similar in appearance to the latter that a good judge might easily be deceived. These lumps were hard, brittle, opaque, and almost black, but minute fragments were reddish and transparent like garnet. The drug was inodorous, of a strongly astringent and sweetish taste, and soluble in water to the extent of about five or six parts out of seven, forming a deep red astringent infusion. There can be little doubt that this variety of kino is a concrete juice, which exudes either spontaneously or from wounds in the bark, and hardens in the air. (*Med. Obs. and Inq.*, i. 358.)

East African Kino.—This drug in external characteristics resembles Malabar kino, but its pieces are very sharply angular. It is the product of the *Pterocarpus Bussei*, Harms, and has been chemically examined by E. Schaer, who states that it contains neither *pyrocatechin* nor *kinoic*, but otherwise affords reactions similar to those of Malabar kino.

5. AUSTRALIAN KINO. *Botany Bay Kino*. *Red Gum*.—This kino was formerly supposed to be yielded by *Eucalyptus resinifera*, but is now known to be produced by a very large number of species. It is occasionally obtained in dry masses in the crevices in trees, sometimes by incisions into the bark, but more usually is simply scraped off the outside of the tree. It has been stated that five hundred pounds of the kino are sometimes yielded in a single year by one tree, but this seems to be a great exaggeration. Occasionally the juice reaches England unevaporated.¹ Australian kino usually occurs in dark, reddish-brown masses or grains, which when sufficiently thin may be translucent and garnet-like. It is very likely to contain much foreign matter, especially the scrapings from the bark. Coming from so many sources, it varies considerably in its physical characteristics and its relations to solvents. Although the Australian kino is produced by so many trees and is much used in Australia, it does not seem to be an important article of commerce. For further information concerning it the reader is referred to an elaborate paper on it by J. H. Maiden,

¹ *Kino juice* has a fine deep red color, a slightly aromatic odor, and a decidedly astringent taste, and on evaporation yields a genuine kino in varying amount. It must not be confounded with the so-called *Liquid Kino*, or *apple tree juice*, which is obtained from incisions in the *Angophora intermedia* or *narrow-leaved apple tree* of Australia. This varies from the consistency and colorlessness of water to an orange brown or reddish-brown liquid as thick as molasses. It contains catechin and tannic acid, and is said to be especially employed for the purposes of tanning nets.

in *P. J.*, Oct. 1889;¹ also *A. J. P.*, 1897, 1. *Eucalyptus kino* contains catechin, pyrocatechin, and kinoin, and in some specimens a volatile oil, giving a slightly aromatic odor to the drug, which is especially developed by hydrochloric acid. (See also *Eucalypti Gummi*.) J. H. Maiden (*A. J. P.*, 1895, 575) states that Australian kino contains *eudesmin* and *aromadendrin*. The former of these when purified exists as a pure white mass with a lustre resembling spermaceti. It is soluble in hot water, but crystallizes out again on cooling. It is soluble in alcohol, ether, acetic ether, and chloroform, but not in benzene, petroleum spirit, or carbon disulphide. It is dissolved by sulphuric acid with a dark color changing to purple, by nitric acid with a beautiful yellow color. Its formula is given as $C_{26}H_{30}O_8$, and its melting point as 99° C. The second substance was also obtained crystallized from boiling water, and melted at 162° C. No analysis has been made of it.

6. MYRISTICA KINO.—There has been produced in Southern India a kino consisting of smaller or larger angular pieces, of deep garnet color, in thin fragments, and having the general characteristics of Malabar kino; according to E. Schaer, it is a product of *Myristica malabarica*, of *M. fragrans*, and probably of other species of the genus. In all important respects these kinos are said to correspond with Malabar kino, but to be distinguishable by containing crystals of calcium tartrate. *Myristica Kino* is probably a distinctive product from the so-called *Syndai varnish*, a rich red fluid obtained from the *Myristica gibbosa*, Hook f., and employed in Assam as a varnish. It is highly astringent and after exposure becomes perfectly impervious, the changes being due to the presence of a ferment or enzyme. As has been shown by D. Hooper (*P. J.*, June 20, 1903), *Syndai varnish*, if kept in corked bottles, gelatinizes in a few weeks. Edmund White made an investigation into the cause of the gelatinization of tincture of kino (*P. J.*, May, 1903), from which it appeared that this phenomenon was due to the presence in the kino of an enzyme belonging to the oxydases, and this enzyme was subsequently isolated by David Hooper from the fresh juice of *Myristica gibbosa* (*Proc. A. Ph. A.*, 1903, 733) yielding an unofficial variety of kino. It is believed by White that this enzyme may be eliminated from the official as well as other kinos by a judicious method of collection, and considers it probable that the following one, adopted by J. G. F. Marshall and described in the "*Agricultural Ledger*" (1900, No. 11, 381), will accomplish this: "A longitudinal cut is made with an axe or knife, called *macha katti*, through the bark of the trees, down to the cambium, about 1½ ft. long, and side cuts are made to lead into

this. A bamboo tube is then fixed at the bottom of the main incision in order to catch the juice. In the course of about twenty-four hours the flow of gum ceases and the bamboo is taken down. When several of these bamboo cups are nearly full they are taken to headquarters and emptied into a large cauldron and the juice boiled. During the boiling, the impurities, consisting of pieces of bark, wood and leaves, rise to the surface and are skimmed off. When sufficiently concentrated to the consistency of a thick extract it is exposed to the sun, in thin layers, in shallow vessels until it is dry enough to crumble to pieces. The kino is then weighed and packed away in wooden cases." (*P. J.*, 1903, 702.)

It is said that catechu, broken into small fragments, has sometimes been sold as kino. Fortunately, little injury can result from the substitution, as the medicinal virtues of the two substances are very nearly the same.

Uses.—Kino is powerfully astringent, and in this country is much used for the suppression of morbid discharges. In *diarrhœa*, not attended with febrile excitement or inflammation, it is often an excellent adjunct to opium and the absorbent medicines, and is a favorite addition to chalk mixture. It is also used in *chronic dysentery* when astringents are admissible; in *leucorrhœa* and *diabetes*; and in *passive hemorrhages*, particularly those from the uterus and the intestines. The infusion may be made by pouring eight fluidounces of boiling water on two drachms of the extract, and straining when cool. Aromatics may be added, if deemed advisable. The dose is a fluidounce (30 Cc.). The proportion of alcohol in the tincture renders it frequently an unsuitable preparation.

Dose, ten to thirty grains (0.65 to 2.0 Gm.).

KRAMERIA. U. S. (Br.)

KRAMERIA [Rhatany]

(kră-mě'ri-ă)

"The dried root of *Krameria triandra* Ruiz and Pavon (Peruvian *Krameria*), *Krameria Ixina* Linné (Savanilla *Krameria*) or of *Krameria argentea* Martius (Para or Brazilian *Krameria*) (Fam. *Krameriaceæ*)." U. S. "The dried root of (1) Para Rhatany, a species of *Krameria*, attributed to *Krameria argentea*, Mart.; or of (2) Peruvian Rhatany, *Krameria triandra*, Ruiz and Pavon." Br.

Krameria Radix, Br., Rhatany Root; Radix Ratanha; Ratanhia, Fr. Cod.; Radix Ratanhia, P. G.; Ratanhiawurzel, G.; Ratania, It.; Ratania (Raiz de), Sp.

There is a difference of opinion among botanists concerning the family to which *Krameria* belongs. Chodat (*Arch. d. Sc. Phys. et Nat.*, t. xxiv., Nov. 1890) placed the genus in a dis-

¹ The descriptions given by authors of this kino vary, because the Australian kinos themselves vary so much. Gathered with different degrees of care, and from probably fifty species of trees, they, of course, must be of varying character.

tinet order by itself,—viz., the Krameriaceæ. Engler and Prantl consider its proper place to be among the Cæsalpinoideæ-Kramerieæ in the fam. Leguminosæ.

Krameria triandra, Ruiz and Pavon, *Flor. Peruv.* i. 61.—The rhatany plant is a shrub, having a long, much-branched, spreading root, of a blackish-red color; with a round, procumbent, very dark colored stem, divided into numerous branches, of which the younger are leafy and thickly covered with soft hairs, giving them a white, silky appearance. The leaves are few, sessile, oblong-ovate, pointed, entire, presenting on both surfaces the same silky whiteness with the young branches. The flowers are lake-colored, and stand singly on short peduncles at the axils of the upper leaves. The stamens are three. The nectary is of four leaflets, the two upper spatulate, the lower roundish and shorter. The fruit is globular, of the size of a pea, surrounded by stiff reddish-brown prickles, and having one or two seeds. It is a native of the Peruvian Andes, growing in dry argillaceous and sandy places. It flowers at all seasons, but is at the height of its bloom in October and November. The root is dug up after the rains, and, according to Tschudi, it is especially obtained in the southern provinces of Peru. Closely allied to it is *K. Ixina*, L., which is, however, distinguished by having four stamens, and occurs in Guiana and Northern Brazil. The name *rhatany* is said to express in the tongue of the Peruvian Indians the creeping character of the plant yielding the root.

Rhatany is received in pieces of various shapes and dimensions, some being simple, some more or less branched, the largest as much as an inch in thickness, derived from the main body of the root, the smallest not thicker than a small quill, consisting of the minute ramifications. The pieces are often nearly cylindrical, and as much as two or three feet in length. Sometimes many of the radicles are united in a common head, which is short, and from half an inch to two inches or more in diameter. The roots are composed of a dark, reddish-brown, slightly fibrous, easily separable bark, and a central woody portion, less colored, but still reddish or reddish yellow.

“Peruvian Krameria.—Root-branches several or many, usually attached to a short, hard, and woody tap-root, which is 1.5 to 4 Cm. thick, roughly fissured, and supporting a knotty, several- to many-headed crown; roots of variable length, rarely exceeding 50 Cm. and usually less than 1 Cm. thick, cylindrical, flexuous or wavy, very flexible; externally light red-brown, more or less marked with dark, scaly patches, especially upward, otherwise smoothish, devoid of transverse fissures; fracture tough and splintery, the pinkish-brown bark occupying less than one-third of the radius, the wood yellowish or pinkish-white, finely radiate; inodorous and of a very astringent taste.

Savanilla and Brazilian Kramerias.—Branches usually occurring detached from the tap-root

and crown, less flexuous than those last described, externally of a purple-brown or chocolate brown, and with numerous transverse cracks or fissures; fracture less tough than that of Peruvian Krameria, the bark and wood both darker, the bark occupying two-fifths or more of the radius, the taste more astringent than that of Peruvian Krameria.” *U. S.*¹

The British Pharmacopœia now recognizes two varieties of rhatany, which it describes as follows. “1. Para Rhatany occurs in cylindrical pieces, and is characterized by its purplish-brown color and smooth thick bark, marked at intervals by deep transverse cracks, and adhering firmly to the wood, which is of a pale reddish-brown color. Fracture short. 2. Peruvian

¹ There are various rhatanies in European commerce, *Savanilla*, or *New Granada Rhatany*, is yielded by the *K. tomentosa*, St. Hil. (*K. Ixina*, var. β), growing in Colombia, British Guiana, and Northern Brazil. According to Flückiger and Hanbury, it is never so knotty and irregular as the true rhatany, and is well distinguished by its dull purplish-brown color, its thick, smooth bark ($\frac{1}{2}$ to $\frac{3}{4}$ the diameter of the wood), marked with longitudinal furrows and here and there deep transverse cracks, and by the bark not easily splitting off. Its tannic acid is different from that of the Peruvian drug. If the powdered root be shaken with water and reduced iron, filtered, and the liquid diluted with distilled water, an intense violaceous color will be produced. *Peruvian Rhatany*, similarly treated, gives a dingy brown. Thin sections of true rhatany, moistened with a ferrous salt, become grayish; *Savanilla rhatany*, violet. *Para Rhatany* was described by Berg in 1865, and is believed to be the root of *K. argentea*. It is in long pieces (some 16 to 20 inches), from an eighth to three-quarters of an inch in thickness, of a dark-gray or brownish color, and, like the *Savanilla*, becoming bluish black when immersed in a solution of ferrous sulphate, owing to the presence of tannic acid in the bark. In this variety the root has a peculiar elasticity distinguishing it from the Peruvian and *Savanilla* varieties. Some of the pieces exhibit numerous corky warts. There are also microscopical characters which distinguish it. Two forms of rhatany which Cotton has described as *Black and Brown Antilles Rhatany*, because produced in these islands, though admitted also to be derived from different places on the neighboring continent, have been pronounced by Flückiger, after a careful examination, to be identical with the *Para rhatany*. (*P. J.*, July, 1870, p. 84.) According to the studies of R. G. Dunwoody, this rhatany contains the same active principles as the root of *K. triandra*, but in slightly less quantity. (*A. J. P.*, 1890.)

A rhatany appeared not long since in the London market from Guayaquil. It is described as a large woody root from one-half inch to two inches in diameter. The bark is of a reddish-brown color with blackish streaks, is thin in comparison to the medullum, is of a fibrous texture, and is somewhat striated on the surface and dotted over with small warts. It has a very astringent taste, but no marked odor. E. M. Holmes thinks that it is not the product of the genus *Krameria*. According to the analysis of Passmore, *Guayaquil rhatany* contains a larger quantity of tannin than the Peruvian drug, but less than the *Para* or the *Savanilla rhatany*. (*P. J.*, xvi, 878.) A spurious rhatany of unknown botanical origin, has appeared in the English market coming from Peru. The root is tapering and varies from two to three and a half inches in length, and a quarter to five-eighths of an inch in diameter. The bark is reddish brown, rough, scaly, and longitudinally grooved. The root has a short fracture and a medullum of about 24 wedge shaped bundles, is odorless and of an astringent taste. For detailed macro- and microscopical descriptions, see P. H. Marsden, *P. J.*, 1901, 618.

According to an analysis made in the University of Wisconsin, the *Krameria lanceolata*, Torrey, of North America, yields 34.5 per cent. of extract and 17 per cent. of tannin, and is therefore richer than the official drug. When treated with iron it strikes a deep-purple color, and is thus easily distinguished from *Para rhatany*, which gives a dirty brown, and from *Savanilla rhatany*, which gives a violet color.

Rhatany is characterized by its dark reddish-brown color and its yellowish woody axis, from which the bark readily separates. The bark is thinner than that of *Para Rhatany*, bright reddish brown internally, and rough and scaly except in the smaller pieces. Fracture splintery." Rhatany is without odor, but has a bitter, very astringent, slightly sweetish taste, which is connected with its medicinal virtues, and is much stronger in the cortical than in the ligneous part. The smallest pieces are therefore preferable, as they contain the largest proportion of the bark. The powder is of a reddish color. The virtues of the root are extracted by water and alcohol, to which it imparts a deep reddish-brown color. From the researches of Vogel, Gmelin, Peschier, and Trommsdorff, it appears to contain tannic acid, lignin, and minute quantities of gum, starch, saccharine matter, and an acid which Peschier considered as peculiar and named *krameric acid*. The tannic acid is in three states: 1st, that of purity, in which it is without color; 2d, that of phlobaphene or anhydride, in which it has lost its astringency and been rendered insoluble by the action of the air; and, 3d, that of extractive, which is a soluble combination of tannin and its anhydride, and is the substance which imparts to the infusion and tincture their characteristic reddish-brown color. (Soubeiran, *J. P. C.*, xix. 596.) The tannic acid of rhatany (*krameric-tannic* or *ratanhia-tannic acid*) is separated by treating the ethereal extract of the bark with alcohol, and evaporating the alcoholic solution. It gives a dark-green precipitate with ferric chloride, a flesh-colored one with gelatin, and none with tartar emetic. (Gmelin.) The tannin of rhatany, in the presence of melted potassium hydroxide, is transformed into *protocatechuic acid* and *phloroglucin*, and with diluted acids gives glucose and a peculiar red coloring principle called *ratanhia red*, $C_{26}H_{32}O_{11}$. (*J. P. C.*, Janv. 1868, p. 73.) The proportion of red astringent matter obtained by Vogel was 40 per cent. The mineral acids and most of the metallic salts throw down precipitates with the infusion, decoction, and tincture of rhatany, and are incompatible in prescription.

In examining a specimen of extract of rhatany from America, Wittstein discovered an alkaloid, which he thought to be identical with tyrosine. A somewhat different result was obtained by Ruge, who, after an examination, showed that the new alkaloid is not identical with tyrosine, for it has the formula $C_{10}H_{13}NO_5$, while that of tyrosine is $C_9H_{11}NO_3$, but is rather homologous with it. Like tyrosine, it is an amido-acid, and forms salts equally with mineral acids and with strong bases. It was called *ratanhine* by Ruge. Gintl (*A. J. P.*, 1869, p. 300) obtained *ratanhine* from *resina d'angelim pedra*, a resin from Brazil. Kriemair has also obtained this principle from a sample of extract of rhatany. (See *A. J. P.*, 1875, p. 266.)

Cold water, by means of displacement or percolation, extracts all the astringency of rhatany,

forming a clear deep-red infusion, which upon careful evaporation yields an almost perfectly soluble extract. The root yields its virtues also to boiling water by maceration, but the resulting infusion becomes turbid upon cooling, in consequence of the deposition of apotheme taken up by the water when heated. By boiling with water a still larger proportion of the apotheme is dissolved, and a considerable quantity of the pure tannin becomes insoluble in cold water, and medicinally inert, either by combining with the starch which is also dissolved, or by conversion into apotheme through the agency of the atmosphere. The decoction is, therefore, an ineligible preparation, and the extract resulting from its evaporation, though greater in weight than that from the cold infusion, contains much less soluble and active matter. Alcohol dissolves a larger proportion of the root than water, but this is owing to the solution of apotheme, and the alcoholic extract contains little if any more of the astringent principle than that prepared by cold water, while it is encumbered with much inert matter. (See *Extractum Krameria*.)

Uses.—Rhatany is generally tonic and powerfully astringent, and may be advantageously given in *chronic diarrhæa*, *passive hemorrhages*, especially *menorrhagia*, some forms of *leucorrhæa*, and in all those cases in which kino and catechu are beneficial. It has long been used in Peru as a remedy in bowel complaints, as a corroborant in cases of enfeebled stomach, and as a local application to spongy gums. Ruiz, one of the authors of the Peruvian Flora, first made it known in Europe. It was not until after the year 1816 that it began to come into general use. It has the advantage over the astringent extracts imported, that, being brought in the state of the root, it is free from adulteration, and may be prescribed with confidence. In the form of infusion, tincture, and extract, rhatany has been used locally in *fissure of the anus*, *prolapsus ani*, and *leucorrhæa*.

Dose, of the powder, twenty to thirty grains (1.3 to 2.0 Gm.); but the decoction (an ounce to the pint) is preferable, the dose being from one to two fluidounces (30 to 60 Cc.).

LACTUCARIUM. U. S.

LACTUCARIUM

(lăc-tù-că'ri-ŭm)

"The concrete milk-juice of *Lactuca virosa* Linné (*Fam. Compositæ*)." *U. S.*

Lactucarium Anglicum, *Lactucarium Germanicum*; Strong-scented Lettuce, Green Endive; *Lactucarium*, *Fr. Ood.*; *Giftlattichsaft*, *G.*; *Lactucario*, *Sp.*

The plants of this genus yield when wounded a milky juice, to which, indeed, they owe their generic name. In some of them this juice possesses valuable narcotic properties. This is the case, among others, with *L. sativa*, *L. virosa*, and *L. altissima*. It was supposed that our native *L. canadensis*, L., or *wild lettuce*, might have similar virtues, and Bigelow was informed by physicians who had employed it that it acts as an anodyne, and promotes the secretion from the skin and kidneys. But, according to Auberger, the milky juice of this plant is of a flat and sweetish taste without bitterness, contains much mannite, but no bitter principle, and is destitute of narcotic properties. (*Ann. Thér.*, 1843, p. 18.) The probability is that it is nearly or quite inert.¹ Therefore, though formerly holding a place in the U. S. Pharmacopœia, it has been discarded. In Europe *Lactuca Scariola*, L., is said to be substituted for the official plant.

Lactuca sativa, Willd., *Sp. Plant.* ii. 1523, B. & T. 161.—The garden lettuce is an annual plant. The stem, which rises above two feet, is erect, round, simple below, and branching in its upper part. The lower leaves are obovate, rounded at the end, and undulating; the upper are smaller, sessile, cordate, and toothed; both are shining, and of a yellowish-green color. The flowers are pale yellow, small, and disposed in an irregular terminal corymb. Before the flower-stem begins to shoot, the plant contains a bland pellucid juice, has little taste or odor, and is much used as a salad for the table, but during the period of inflorescence it abounds in a milky juice, which readily escapes from incisions in the stem, and has been found to possess decided medicinal as well as sensible properties. The juice is more abundant in the wild than in the cultivated plants. The original native country of the garden lettuce is unknown. The plant has been cultivated from time immemorial, and flourishes equally in hot and temperate latitudes. Some botanists suppose that *L. virosa* of the old continent is the parent of all the varieties of the cultivated plant.

Lactuca virosa, Willd., *Sp. Plant.* iii. 1526; Woodv., *Med. Bot.*, p. 75, t. 31; B. & T. 160. The *acrid* or *strong-scented lettuce* is biennial, with a stem from two to four feet high, erect, prickly near the base, above smooth and divided into branches. The lower leaves are large, oblong-ovate, undivided, toothed, commonly prickly on the under side of the midrib, sessile, and horizontal; the upper are smaller, clasping, and often lobed; the bracts are cordate and

pointed. The flowers are numerous, of a sulphur-yellow color, and disposed in a panicle. The plant is a native of Europe.

L. virosa is lactescent, and has a strong disagreeable odor like that of opium, and a bitterish, acrid taste. It was admitted by the late Edinburgh and Dublin Pharmacopœias as one of the sources of lactucarium, which it is said to yield in greater quantity and of better quality than the garden lettuce. Schutz of Germany, obtained only 17 grains, on the average, from a single plant of the garden lettuce, while a plant of *L. virosa* yielded 56 grains.

Lactucarium is chiefly produced in Scotland, in Rhenish Prussia, and in France. According to Fairgrieve, in Scotland¹ the plant cultivated is *L. virosa*, var. *montana*. Late in July or early in August the collectors proceed over the field, cutting the head of each stalk and scraping the flow into their vessels. This is repeated several times daily until the plants are exhausted. (*P. J.*, iii. 972.) Auberger is said to have been the only French producer. He cultivated the *L. altissima*, a gigantic Caucasian plant, which reaches the height of 9 feet. In collecting, transverse incisions were made daily, beginning at the top. In Germany the plan is the same as that practised in Scotland.²

Lactucarium,³ as brought from England, is in small, irregular lumps, about the size of a pea or larger, of a reddish-brown color externally, and of a narcotic odor and bitter taste. As prepared near Edinburgh, it is commonly in roundish, compact, and rather hard masses, weighing several ounces. (Christison.) A variety known in our market as *German lactucarium* is in pieces about an inch and a half long by an inch in thickness, four-sided, with one side convex and the three others flat, or slightly concave from shrinking, as if quarter sections of a saucer-shaped cake which had been divided before it was quite dry. The color on the outer or convex surface is darkish brown, that of the cut surfaces light yellowish brown. From experiments by Parrish and Bakes, the German appears to be inferior to the English, as 44 per cent. of spirituous extract was obtained from the latter, and only 36 per cent. from the former, while the two extracts were about equal in their sensible properties. (*A. J. P.*, 1860, p. 226.) French lactucarium resembles the German, except in being in circular cakes about an inch and a half in diameter. The official description is as follows: "Usually in quarter sections of hemispherical masses, or in irregular, angular pieces;

¹ An investigation of our native *Lactuca canadensis* by Malsch has led to conclusions differing essentially from those of Auberger. The milky juice collected by Malsch himself from plants in his neighborhood was converted quickly into a gelatinous mass, that shrunk much in drying, and, so far from a flat taste, had a persistent bitterness, and a heavy, nauseous, narcotic odor. Having prepared a syrup from this concrete juice, he gave it for trial to Da Costa and August Müller, who found it decidedly useful, and by the latter physician it was pronounced quite equal to the imported German lactucarium. (*A. J. P.*, 1869, p. 145.)

² For the mode of cultivating and preparing lactucarium in England, see a communication by Thos. Fairgrieve to *P. J.*, June, 1873, p. 972.

³ For various plans which have been suggested for collecting the drug, see 14th ed. U. S. D.

⁴ The *thridace* of François, at one time supposed to be identical with lactucarium, is in all probability nothing more than the inspissated expressed juice of lettuce, and, indeed, was directed as such in the French Codex of 1837, the leaves being rejected, and the stalks alone, near the flowering period, being subjected to pressure.

externally dull reddish-brown or grayish-brown; internally light brown or yellowish, the cut surface having a waxy lustre and somewhat porous; odor distinct, opium-like; taste strongly bitter. Lactucarium is partly soluble in alcohol and in ether. When triturated with water it yields a turbid mixture. When boiled with water it softens and yields a brownish-colored liquid which, after cooling, is not colored blue by iodine T.S." *U. S.* In color, taste, and odor, lactucarium bears considerable resemblance to opium, and has sometimes been called *lettuce opium*. It does not attract moisture from the air. It yields nearly half its weight to water, with which it forms a deep-brown infusion. It is partly soluble in ether and alcohol. From its resemblance in sensible properties and therapeutic effects to opium, it was conjectured to contain morphine, or some analogous principle, but this conjecture has not yet been verified. Buchner, Aubergier, and Walz claim severally to have discovered the active principle, which has been named *lactucin*, but the substances obtained by these different chemists are not exactly identical in properties, and the lactucin of Walz and Aubergier is considered by Lenoir as owing its bitterness to impurities, separated from which it is without taste and inert. For a full account of the earlier analyses of lactucarium, see 16th edition *U. S. D.* Ludwig found, in 100 parts, 48.63 of substances insoluble in water, and 51.37 of substances soluble in water. Of the insoluble matter 42.64 parts were of *lactucerin* or *lactucone*, in snow-white aggregated granules, dissolving in strong hot alcohol which deposits it on cooling, readily soluble in ether but insoluble in water, incapable of saponification by potassium hydroxide, and therefore not properly a fat, and in alcoholic solution faintly reddening litmus paper. On the other hand, Hesse states that lactucone is a mixture of esters, of which one, $C_{36}H_{58}O_2(C_2H_5O)_2$, is a diacetyl ester yielding, when saponified, α -lactuceryl, $C_{36}H_{56}O_2$, and acetic acid, while the other is a mono-acetyl ester, $C_{36}H_{56}O_2(C_2H_5O)$.¹ Of the 51.37 parts soluble in water, 6.98 were albumen, 1.75 lactucerin; held in solution by other substances, 27.68 bitter extract soluble in water and in alcohol, and 14.96 aqueous extract insoluble in alcohol of 0.830. The former of these extracts was found to contain a peculiar acid substance called *lactucic acid*, and the lactucin of Aubergier. *Lactucic acid* is of difficult crystallization, light yellow, strongly bitter, without sour taste, of an acid reaction, and readily soluble in alcohol and water. It has as much claim as any other discovered substance to be considered the active principle of lactucarium.

The assertion sometimes made that *Lactuca virosa* contains a mydriatic alkaloid has been disproved by J. C. Braithwaite and H. E. Stevenson, *P. J.*, 1903, 148. Farr and Wright (*P. J.*, 1904, p. 16) claim, however, to have definitely established the presence of a mydria-

tic alkaloid, giving alkaloidal reactions with Mayer's and Thresh's reagents, and producing a powerful mydriatic effect upon the eye. Besides the above ingredients, Ludwig found in lactucarium a substance resembling mannite, oxalic acid, another organic acid not well determined, a soft resin, potassium, magnesium, and ferric oxide. Distilled with diluted sulphuric acid, it gave an acid product smelling like lactucarium, which, saturated with calcium carbonate, and again distilled with potassium bisulphate, yielded an acid fluid having the odor of valerian. (*A. J. P.*, xx, 57.)

Kromayer (*Ann. Ch. Ph.*, 105, p. 3) found also *lactucopikrin*, $C_{44}H_{72}O_{31}$, a brown, amorphous, and very bitter substance of weak acid reaction. It is easily soluble in water and alcohol. Ludwig's lactucic acid Kromayer considers to be an oxidation product of lactucopikrin.

Hesse (*Handwörterbuch*, iv, p. 8) prepared *lactucerin*, and finds it to crystallize in white needles, fusing point $210^{\circ} C.$, soluble in hot ligroin, chloroform, and benzene. On fusion with potassium hydroxide it yields acetic acid and *lactuceryl alcohol*, $C_{18}H_{30}O$, which forms white needles, fusing at $162^{\circ} C.$, and is easily soluble in ether, chloroform, and hot alcohol. Hesse has since (*Ann. Ch. Ph.*, 234, p. 243) determined that lactucarium contains the acetates of α - and β -lactuceryl, $C_{18}H_{30}O$. These compound ethers are saponified with alcoholic potash and water added, which precipitates α - and β -lactuceryl. These are washed, dried in the air, and taken up with boiling alcohol. On cooling, α -lactuceryl separates out first and can be purified by recrystallization, while the β -lactuceryl is obtained from the mother liquor. The acetate of α -lactuceryl fuses at $210^{\circ} C.$, while that of β -lactuceryl fuses at $230^{\circ} C.$ For an examination of *Russian lactucarium*, by L. Schiperovitch, see *Ph. Z. R.* or *D. C.*, 1886.

Uses.—The ancients believed that lettuce had soporific properties, and many years ago J. R. Coxe of Philadelphia, first proposed the employment of the inspissated milky juice as a medicine. It was chiefly, however, through the recommendation by Duncan Sr., of Edinburgh, that the medicine came into use and was adopted as official in various pharmacopœias. It is claimed for it that it has, although in a very much inferior degree, the anodyne and calming properties of opium, without its disposition to derange the digestive organs. It has been employed in this country to some extent to allay cough and quiet nervous irritation, but we believe that the general experience is in accord with our own in finding it to be almost devoid of narcotic properties. We have never been able to obtain any good results from its use. Water distilled from lettuce (*eau de laitue*) is used in France as a mild sedative, in the quantity of from two to four ounces. The fresh leaves boiled in water are sometimes employed in the shape of cataplasm. It is said that in Egypt a mild oil is derived from the seeds, fit for culinary use.

Dose, ten to twenty grains (0.65 to 1.3 Gm.), but much larger quantities may be given without obvious effects.

Off. Prep.—Syrupus Lactucarii, *U. S.* (from tincture); Tinctura Lactucarii, *U. S.*

LAMELLÆ.

DISCS

(lā-mēl'læ)

Gelatina Medicata in Lamellis; Medicated Gelatin Disks; Disques de Gélatine, *Fr.*; Gelatinlamellen, *G.*

Under this head are included in the British Pharmacopœia minute *gelatin discs* which contain traces of alkaloids, and which are designed to be inserted by oculists under the eyelid, in order to produce, through solution in the tears, such effects as they desire. A hot solution of gelatin containing the alkaloid in proper proportion is poured on a slightly greased glass or porcelain plate, cooled and dried, and then cut into discs, which, by previous calculation, will be found to contain the requisite quantity of medicament. A little glycerin is added to keep them from getting too hard and dry.

LAMELLÆ ATROPINÆ. Br.

DISCS OF ATROPINE

(lā-mēl'læ āt-rō-pī'næ)

Disques d'Atropine, *Fr.*; Atropinplättchen, *G.*

"Dises of Gelatin, with some Glycerin, each weighing about 1.50 grain (1.3 milligrammes), and containing 1.5000 grain (0.013 milligramme) of Atropine Sulphate." *Br.*

LAMELLÆ COCAINÆ. Br.

DISCS OF COCAINE

(lā-mēl'læ cō-cā-pī'næ)

Disques de Cocaine, *Fr.*; Cocainplättchen, *G.*

"Dises of Gelatin, with some Glycerin, each weighing about 1.30 grain (2.17 milligrammes), and containing 1.50 grain (1.3 milligrammes) of Cocaine Hydrochloride.

Each Disc is four times the strength of a Disc of Cocaine of the British Pharmacopœia of 1885." *Br.*

LAMELLÆ HOMATROPINÆ. Br.

DISCS OF HOMATROPINE

(lā-mēl'læ hō-māt-rō-pī'næ)

Disques d'Homatropine, *Fr.*; Homatropinplättchen, *G.*

"Dises of Gelatin, with some Glycerin, each weighing about 1.50 grain (1.3 milligrammes), and containing 1.100 grain (0.65 milligramme) of Homatropine Hydrobromide." *Br.*

Lucas (*C. D.*, 1899, 959) furnishes an improved formula for these discs; it is as follows:

Gelatin, 30 gr.; Glycerin, 3 gr.; Distilled water, 150 gr.; Homatropine hydrobromide, 10 gr. Dissolve and pour on to a waxed plate, so as to produce a film exactly 4 inches square. When dry, but still supple, punch out discs 1-7 inch diameter.

The product is about 784 discs, the remainder of the film being wasted. Each disc will weigh rather less than 1-20 gr. No inconvenience has been found in using discs weighing 1-15 gr., as, owing to their extreme tenuity, they soften as soon as they are inserted beneath the eyelid.

LAMELLÆ PHYSOSTIGMINÆ. Br.

DISCS OF PHYSOSTIGMINE

(lā-mēl'læ phy-sō-stig-mī'næ)

Disques d'Esérine, *Fr.*; Physostigminplättchen, *G.*

"Dises of Gelatin, with some Glycerin, each weighing about 1.50 grain (1.3 milligrammes), and containing 1-1000 grain (0.065 milligramme) of Physostigmine Sulphate." *Br.*

LAPPA. U. S.

LAPPA [Burdock Root]

(lāp'pa)

"The dried root of *Arctium Lappa* Linné, or of other species of *Arctium* (Fam. *Compositæ*), collected from plants of the first year's growth." *U. S.*

Radix Bardanæ, Bazzles, Beggars' Buttons, Cuckoo Button, Harebur; Bardane, *Fr. Cod.*; Glouteron, *Fr.*; Klettenwurzel, *G.*; Bardana, *It.*

The stem of the burdock is succulent, pubescent, branching, and three or four feet in height, bearing very large, cordate, denticulate leaves, which are green on their upper surface, whitish and downy on the under, and stand on long footstalks. The flowers are purple, with heads globose, and in terminal panicles. The involucre consists of imbricated scales, with hooked extremities, by which they adhere to cloth and the coats of animals. The achenes are oblong, somewhat compressed and three-angled, ribbed, truncate. Although a native of Europe, burdock is abundant in the United States, where it grows on the roadsides, among rubbish, and in cultivated grounds. There are three recognized species of *Arctium* in North America,—viz., *A. tomentosum* (Lam.), Schk. (Woolly or Cottony Burdock); *A. Lappa*, L. (Burdock, Clotbur or Great Bur); and *A. minus*, Schk. (Common Burdock).

The burdock has a simple, spindle-shaped root a foot or more in length, brown externally and white and spongy within, furnished with thread-like fibres, and having withered scales near the top. It is officially described as "nearly simple, fusiform, of variable length, 5 to 20 Mm. in diameter near the crown; frequently split or in broken pieces, externally grayish-brown, longitudinally wrinkled, the

crown somewhat annulate, sometimes surmounted by a woolly tuft of leaf remains; fracture somewhat horny; a dark cambium separating the thick brownish bark from the yellowish porous and radiate wood, centrally hollow or containing a white pith-like tissue; odor slight; taste mucilaginous, sweetish, and slightly bitter." *U. S.* For medicinal purposes the root should be gathered when about a year old.

Inulin has been found in it by Guibourt, and sugar by Fée, while F. E. Hendershott believes that it contains a glucoside, besides arabin and pectin and extractives. (*Proceedings of Mich. Pharm. Assoc.*, 1887.) Trimble also obtained from the root a bitter, crystalline glucoside. (*Ph. Era*, 1888, p. 133.) Thos. Donaldson (*A. J. P.*, 1890, p. 123) found 8.6 per cent. of yellow fixed oil and about 1 per cent. of white waxy matter. A small quantity of volatile oil (0.065 per cent.) has been found in burdock root according to *Haensel's Report*, Oct. 1902. The inulin usually exists in parenchymatous cells in a different state, but if sections of the green root be dehydrated by soaking in 95 per cent. alcohol, the inulin will be found in spheroidal form.

An interesting account of burdock and its use as an edible vegetable in Japan, by Inazo Nitobe, may be found in *A. J. P.*, 1897, 416.

Uses.—Burdock root is considered to be a diuretic and diaphoretic alterative, especially useful in the *gouty*, *scorbutic*, and *syphilitic* and *scrofulous diatheses*; also in various chronic skin diseases, especially in *psoriasis*, *prurigo*, and *acne*. (*M. S. Rep.*, 1868.) To prove effectual, its administration must be long continued. A pint may be given daily of the decoction, made by boiling two ounces of the root in three pints of water to two pints. The fluidextract and syrup have also been prepared. The fresh leaves have been employed both externally and internally in cutaneous eruptions and ulcerations. The fruit has been largely substituted for the root, especially in the form of the tincture of burdock fruit.

Dose, thirty to ninety grains (2 to 5.8 Gm.).

Off. Prep.—Fluidextractum Lappæ, *U. S.*

LAUROCERASI FOLIA. Br.

CHERRY-LAUREL LEAVES

(lâp'rô-cēr'ā-sī fō'li-ā)

"The fresh leaves of *Prunus Laurocerasus*, *Linn.*" Br. (Fam. Rosaceæ.)

Cherry Bay; Laurier-cerise, *Fr. Cod.*; Kirschlorbeer, *G.*; Lauroceraso, *It.*; Laurel-cerezo (Hoja de), *Sp.*

Prunus Lauro-cerasus, Willd., *Sp. Plant.* ii. 898; B. & T. 98. *Cerasus Lauro-cerasus*, De Cand., *Prodrom.* ii. 540.—This is a small evergreen tree, rising 15 or 20 feet, with long spreading branches, which, as well as the trunk, are covered with a smooth, blackish bark. The

leaves, standing alternately on short strong footstalks, are oval-oblong, from five to seven inches in length, acute, finely toothed, firm, coriaceous, smooth, beautifully green and shining, with oblique nerves, and yellowish glands at the base. The flowers are small, white, strongly odorous, and disposed in simple axillary racemes. The fruit is an oval drupe, very similar in shape and structure to a small black cherry. The cherry-laurel is a native of Asia Minor, but is cultivated in Europe, both for medicinal use and for the beauty of its shining evergreen foliage. Almost all parts of it have more or less of the odor of hydrocyanic acid.

In their recent and entire state cherry-laurel leaves have scarcely any odor; but, when bruised, they emit the characteristic odor of the plant in a high degree. Their taste is somewhat astringent and strongly bitter, with the flavor of the peach kernel. They are officially described as "thick, coriaceous, on short strong petioles, oblong, or somewhat obovate, from five to seven inches (twelve and a half to seventeen centimetres) in length, tapering towards each end, recurved at the apex, distantly but sharply serrate and slightly revolute at the margins, dark green, smooth, and shining above, much paler beneath, and with a prominent midrib, on either side of which, near the base, are one or two glandular depressions." *Br.* They yield a peculiar oil and hydrocyanic acid by distillation with water, which they strongly impregnate with their flavor. One pound, avoirdupois, of the fresh leaves yields 40.5 grains of the oil. (*Ph. Cb.*, 1855, 205.) The oil resembles that of bitter almonds, for which it is said to be sometimes sold in Europe, where it is employed to flavor liquors and various culinary preparations, but, as the glucoside of cherry-laurel leaves is decomposed more slowly than ordinary crystallized amygdalin, it is liable to hold hydrocyanic acid, and hence to be poisonous. The glucoside referred to has been termed *laurocerasin*, or "amorphous amygdalin." It is decomposed by emulsin into hydrogen cyanide, benzaldehyde, and sugar, but more slowly than ordinary amygdalin. Its optical activity also differs from that of ordinary amygdalin. (Jacobsen, *Die Glykoside*, 25.) That the oil exists already formed, to a certain extent, in the fresh leaves, is rendered probable by the fact, stated by Winckler, that they yield it in considerable quantity when distilled without water. (*J. P. C.*, xxv. 195.) The fresh leaves are used to flavor milk, cream, etc., and more safely than the oil, though they also are poisonous, when too largely employed.

Uses.—The leaves of the cherry-laurel possess properties similar to those of hydrocyanic acid, and the water distilled from them is much employed in various parts of Europe for the same purposes as that active medicine. But it deteriorates by age, and therefore, as kept by pharmacists, must be of variable strength. J. Bröker, a Dutch pharmacologist, has satisfied

himself, by numerous experiments, that the proportion of hydrocyanic acid in the leaves varies with the season, the age of the plant, the character of the soil and of the weather, and thinks that, in consequence of this variability, they are inferior for medicinal use to bitter almonds, which in this respect have a more uniform composition. He found the proportion of the acid in the leaves greatest in July, and least in February. (*B. F. M. R.*, Oct. 1868, p. 517.) It is not, therefore, to be regretted that the want of the plant in this country has prevented the general introduction of so variable a remedy as the distilled water. (See *Aqua Laurocerasi*.)

Off. Prep.—*Aqua Laurocerasi*, Br.

LEPTANDRA. U. S.

LEPTANDRA [Culver's Root]

(lep-tăn-dră)

"The dried rhizome and roots of *Veronica virginica* Linné (Fam. *Scrophulariaceæ*)."
U. S.

Culver's Physic, Black Root; Racine de Leptandra, ou de Véronique de Virginie, Fr.; Leptandra-Wurzel, G.

Veronica virginica, Linn.; Gray, *Man. of Bot.*, etc. p. 290. *Leptandra virginica*, Nuttall, *Genera of N. Am. Plants*, i. 7; Rafinesque, *Med. Flora*, vol. ii.—This plant, commonly called *Culver's root*, or *Culver's physic*, is an herbaceous perennial, with a simple, erect stem, three or four feet high, smooth or downy, furnished with leaves in whorls, and terminating in a long spike of white flowers. The leaves, of which there are from four to seven in each whorl, are lanceolate, pointed, and minutely serrate, and stand on short footstalks. A variety was seen by Pursh with purple flowers, which was described and figured as a distinct species by Rafinesque, under the name of *L. purpurea*. The plant flowers in July and August. It grows throughout the United States east of the Mississippi, affecting mountain meadows in the South and rich woods in the North, and is not unfrequently cultivated.

Properties.—The root consists of a rhizome or root-stalk several inches in length, sometimes branched, with numerous long slender radicles. As found in commerce, the rhizome is usually broken into pieces an inch or more long, from two to four lines in thickness, either beset with the rootlets or very rough from their remains when broken, hard and firm, and of difficult fracture, dark brown externally, light-colored and ligneous within. The rootlets are round, smooth, slender, generally broken, but, when not so, six inches or more in length, and almost black, being much darker than the caudex. The official description is as follows: "Rhizome of horizontal or oblique growth, somewhat bent and branched, from 4 to 15 Cm. long and 3 to 8 Mm. in diameter; externally gray-brown to blackish-brown, with

cup-shaped scars on the upper side; annulate, the inferior and lateral surfaces with coarse roots and root-scars; fracture tough and woody, branches readily separable from the main rhizome; internally, bark dark brown, 0.3 to 1 Mm. thick, wood hard, yellowish, pith large, purplish-brown; roots slender, longitudinally wrinkled, fragile; odor slight; taste bitter, slightly acid." *U. S.* The odor is feeble and not disagreeable, the taste bitterish, somewhat nauseous, and feebly acid. Water and alcohol extract the virtues of the root. For a microscopical description of leptandra, by A. P. Breithaupt, see *A. J. P.*, 1897, 235. According to E. S. Wayne of Cincinnati, it contains volatile oil, extractive, tannin, gum, resin, and a peculiar crystalline principle, to which the virtues of the medicine may be ascribed. To this principle the name of *leptandrin* properly belongs. F. F. Mayer confirmed the presence of the crystalline principle, and proved it to be a glucoside. Wayne obtained it by treating an infusion of the root with lead subacetate, filtering, precipitating the excess of lead by sodium carbonate, filtering to separate the lead carbonate, passing the filtered liquid through animal charcoal which absorbed all the active matter, washing the charcoal with water until the washings began to be bitter, then treating it with boiling alcohol, and allowing the alcoholic solution to evaporate spontaneously. By dissolving the powder thus obtained in water, treating this with ether, and allowing the ether to evaporate, needle-shaped crystals were obtained, which had the bitter taste of the root. The resinous matter obtained by making a tincture of the root and precipitating this with water has been improperly called leptandrin, and considered the active principle. The pure resin is probably inert, and the preparation referred to owes what activity it may possess to some of the true leptandrin associated with it. Leptandrin is soluble in water, alcohol, and ether. It has not been isolated for use. (*Proc. A. Ph. A.*, 1856, p. 34.) Subsequently Wayne obtained from the root a saccharine principle having the properties of *mannite*. (*A. J. P.*, 1859, p. 557.) G. Steinmann (*A. J. P.*, 1887, p. 229) obtained pale lemon-yellow crystals of a peculiar agreeable odor and a very bitter taste. They were not precipitated from solution by Mayer's reagent or by tannin, and did not yield glucose on being boiled with diluted sulphuric acid.

Uses.—The recent root is said to act violently as a cathartic, and sometimes as an emetic. In the dried state it is much milder, but less certain. The practitioners calling themselves eclectics consider it an excellent cholagogue, and use both the impure resin, which they call leptandrin, and the root itself as a substitute for mercurials.¹ A. P. Dutcher of Cleveland,

¹ J. U. Lloyd communicated a process for resin of leptandra (or leptandrin) to the American Pharmaceutical Association in 1880. (See *A. J. P.*, 1880, 491.)

Ohio, has not found it to act decidedly on the liver, but believes that it has a special influence on the muciparous follicles of the intestines, and acts very advantageously in cases of *duodenal indigestion and chronic constipation*. (*M. S. Rep.*, March 28, 1868.) Rutherford, in his experiments upon dogs, found leptandrin to act rather feebly upon the liver.

Dose, fifteen to sixty grains (1 to 3.9 Gm.); of the impure resin, two to four grains (0.13 to 0.26 Gm.).

(lî-mō'nîs sūc'cus)

"The freshly expressed juice of the ripe fruit of *Citrus Limonum* Risso (Fam. *Rutaceæ*)." *U. S.* "The freshly expressed juice of the ripe fruit of *Citrus medica, Linn.*, var. β *Limonum, Hook. fil.*" *Br.*

Succus Limonis, Br., **Succus Citri; Lime Juice; Suc de Citron (de Limon), Fr. Cod.; Citronensaft, Limonensaft, G.; Succo di limone, It.; Zumo de limon, Sp.**

For some general remarks on the genus *CITRUS*, see *Aurantii Cortex*.

Citrus medica, Willd., Sp. Plant. iii. 1426; *Woodv., Med. Bot.*, p. 582, t. 189.—This tree closely resembles *Citrus Aurantium*, before described. The leaves, however, are larger, slightly indented at the edges, and stand upon footstalks which are destitute of the winged appendages that characterize the other species. The flowers, moreover, have a purplish tinge on their outer surface, and the fruit is entirely different in appearance from the orange. There are several varieties of *Citrus medica*, which some botanists consider as distinct species, but which scarcely differ except in the character of their fruit. Those particularly deserving of notice are the citron, lemon, and lime. 1. In the *citron, C. medica* of Risso (*Bentley & Trimen, p. 53*), the fruit is very large, sometimes six inches in length, ovoidal,

with a double rind, of which the outer layer is yellowish, thin, unequal, rugged, with innumerable vesicles filled with essential oil; the inner is white, very thick and spongy. It is divided in the interior into nine or ten cells, filled with oblong vesicles, which contain an acid juice precisely like that of the lemon, and used for the same purposes. The rind is applied to the preparation of conserves, to which it is adapted by its thickness. The fruit is called *cédrat* by the French. 2. The *lemon (C. medica, var. limon* of Linnæus, *Citrus Limonum* of Risso) (*Bentley & Trimen, p. 54*) is smaller than the preceding, with a smoother and thinner rind, a pointed nipple-shaped summit, and a very juicy, acid pulp. In other respects it closely resembles the citron, to which, however, it is usually preferred in consequence of the greater abundance of its juice. 3. The *lime* is still smaller than the lemon, with a smoother and thinner rind, oval, rounded at the extremities, of a pale-yellow or greenish-yellow color, and abounding in a very acid juice, which renders it highly useful for the purposes to which the lemon is applied. It is the product of the variety *C. acris* of Miller. According to E. M. Holmes the West India limes are much richer in acid than are those produced in the South of Europe; the juice of the spineless variety was found to contain 37.73 grains per ounce; the ordinary West India lime 36.15 grains per ounce; the Sicily lime 30.32 grains per ounce.¹

The *Citrus medica*, like the orange-tree, is a native of Asia. It is now known to grow wild in Northern India, and was introduced into Europe from Persia or Media. It was first cultivated in Greece, afterwards in Italy, as early as the second century, and has now spread over the whole civilized world, being raised by artificial heat where the climate is too cold to admit of its exposure during winter to the open air.

¹ *Lime juice as a beverage.*—We are indebted to Frank C. Simson of Halifax, for the following communication upon this subject. Lime juice is used very largely as an antiscorbutic. It is "the juice of *Citrus Limetta*, produced most largely in Jamaica and other West India Islands. It is obtained from both cultivated and wild trees, the former being superior in flavor while the latter contains a larger portion of citric acid. The tree resembles closely the *Citrus Limonum* and furnishes two crops annually which extend over a period of three months each.

"*Preparation.*—Properly picked limes are sliced and pressed between wooden rollers, care being taken that the pressure is not too great, in order to prevent the oil from being expressed with the juice; such portions of the oil as are expressed are collected in the pulp and set aside for future distillation. The juice at first is milky white, but after standing for some time separates from the pulp, part floating and the other part sinking; it then goes through the usual process of filtering through pulp or paper. The use of the juice as a beverage and febrifuge has increased many hundred fold in the last few years, and is now considered superior to any juice of the *Citrus* family. The juice should contain from 61 to 9 per cent. citric acid. This varies as to the quality of the fruit and the district from which it is produced, Jamaica producing the best. The article is much sophisticated as found ordinarily in commerce, being often largely adulterated with tartaric acid, and even mineral acids are sometimes used."

We are supplied with lemons and limes chiefly from the West Indies, the Mediterranean and California. Though the former of these fruits only is directed by the United States Pharmacopœia, both kinds are employed indiscriminately for most medicinal purposes, and the lime affords a juice at least equal, in proportional quantity and acidity, to that obtained from the lemon.¹

As lemons rapidly deteriorate on keeping, if exposed to the air, the suggestions of protecting them by dipping them in melted paraffin, or by using a varnish of shellac dissolved in alcohol, made by George Mee of London, are not without value. Mee found that lemons thus covered with varnish continued sound for a period of many months. (See *A. J. P.*, 1866, p. 474.)

Properties.—The exterior rind of the lemon has a fragrant odor, and a warm, aromatic bitter taste, somewhat similar to that of the orange, though less agreeable. It is usually found in narrow, thin bands, with very little of the spongy, white, inner layer adhering to it, and is officially described as follows: "Outer surface lemon-yellow, the tissue beneath containing numerous large oil reservoirs; odor highly fragrant; taste pungently aromatic." *U. S.* It contains a bitter principle, and yields, by expression or distillation, an essential oil, which is much used for its flavor. Both this and the rind itself are recognized in the Pharmacopœias. (See *Oleum Limonis.*) When the white, spongy portion of the rind is boiled in water, and the decoction evaporated, crystals are deposited of a substance called *hesperidin*. This is a glucoside, and has the formula $C_{22}H_{32}O_{12}$, and is decomposed by diluted acids into hesperetin, $C_{16}H_{14}O_6$, and glucose, $C_6H_{12}O_6$. It turns dingy black when gently warmed with alcoholic solution of ferric chloride. It is bitter, but as it is found most largely in the spongy and comparatively tasteless part of the rind, it may be doubted whether it is entitled to be considered as the active bitter principle. (See *A. J. P.*, xxvi. 553.) Lemon peel yields its virtues to water, wine, and alcohol. E. G. Clayton (*An.*, 19, 134) calls attention to the distinction between lemon peel and orange peel when moistened by strong hydrochloric acid. Orange peel under these circumstances changes in color from a yellow to a rich dark green color, while lemon peel retains its hue or assumes a dingy yellowish-brown tint. The juice is the part for which the fruit is most esteemed. It is sharply acid, with a peculiar grateful flavor, and consists chiefly of water, citric acid (about 10 per cent.), gum and sugar (from 3 to 4 per cent.), and inorganic salts (2.28 per cent.). It sometimes has in it a little volatile oil, derived by pressure from the rind. The *U. S. P.* gives the following standard tests: "A

slightly turbid, yellowish liquid, having the odor of lemon; taste acid and often slightly bitter. Specific gravity: 1.030 to 1.040 at 25° C. (77° F.). It reddens blue litmus paper and should contain from 7 to 9 percent. of citric acid. If a few drops of barium chloride T.S. be added to filtered Lemon Juice, no turbidity or white precipitate should be produced (absence of *sulphuric acid* or *sulphates*). If an equal volume of sulphuric acid containing a few drops of alcohol be added to Lemon Juice, and the liquid heated, no odor of acetic ether should be developed (absence of *acetic acid*). Upon the addition of solution of potassium acetate (1 in 3) and alcohol in excess, no white crystalline precipitate should form after allowing the liquid to stand fifteen minutes (absence of *tartaric acid*). At least 10 Cc. of normal potassium hydroxide V.S. should be required to neutralize 10 Cc. of Lemon Juice, phenolphthalein T.S. being used as indicator." *U. S.* "A slightly turbid yellowish liquid, with a sharply acid taste. Specific gravity 1.030 to 1.040. One fluid ounce contains 30 to 40 grains (or 100 cubic centimetres contain 7 to 9 grammes) of citric acid. When Lemon Juice is evaporated to dryness, and the residue is incinerated, it should yield not more than 3 per cent. of ash. 110 minims (or 100 cubic centimetres) of Lemon Juice are neutralized by about 11½ grains (or 11.4 grammes) of Potassium Bicarbonate, by about 9½ grains (or 9.5 grammes) of Sodium Bicarbonate, and by about 16½ grains (or 16.5 grammes) of Sodium Carbonate." *Br.*

As lemons cannot always be obtained, the juice is often kept in a separate state, but, from its liability to spontaneous decomposition, it speedily becomes unfit for medicinal use, and, though various means have been resorted to for its preservation, it can never be made to retain for any length of time its original flavor unaltered. The best substitute for lemon juice is a solution of crystallized citric acid in water, in the proportion of about an ounce to the pint, with the addition of a little oil of lemon, but even this solution is nearly useless as an antiscorbutic. One of the most effectual methods of preserving the juice is to allow it to stand for a short time after expression, until a coagulable matter separates, then to filter, and introduce it into glass bottles, with a stratum of almond oil or other sweet oil upon its surface. It will keep still better if the bottles containing the filtered juice be suffered, before being closed, to stand for fifteen minutes in a vessel of boiling water. Another mode is to add one-tenth of alcohol and to filter. The juice may also be preserved by concentrating it either by evaporation with a gentle heat, or by exposure to a freezing temperature, which coagulates the aqueous portion and leaves the juice much stronger than before. When used, it may be diluted to the former strength, but, though the acid properties are retained, the flavor of the juice is found to have been deteriorated. Lemon syrup is another form in which the juice is preserved.

¹ *Limeseed Oil.*—The seed of the lime contains 58 per cent. of fixed oil, which is said to equal in flavor the best olive oil. Its tendency to resist rancidity is reputed to be very great. (*B. C. D.*, 1894, 411.)

The British Pharm. (1885) gave the sp. gr. of lemon juice at from 1.035 to 1.045, and the quantity of citric acid in a fluidounce of it from 30 to 40 grains. W. W. Stoddart found, in lemons from six different sources, an average of 42.53 grains in an ounce of the juice, and a mean sp. gr. of 1.044. By other authorities the proportions are given very differently. Thus, Watts gives 20.5 grains to the ounce, or 4.7 per cent. of the juice. The fact is that the quantity of acid varies very greatly. Stoddart found it to diminish rapidly with the advance of summer, with little change in the sp. gr. (*P. J.*, Oct. 1863.) H. H. Robins, after examining large consignments of lemons, states that the average yield taken from a year's receipts was 35.23 grains in a fluidounce. (*C. D.*, 1896, 742.) A solution of tartaric acid in water, with the addition of a little sulphuric acid, and flavored with the oil of lemon, has been fraudulently substituted for lemon juice, particularly as an antiscorbutic on long voyages, for which purpose it is quite useless. An application of the test for tartaric and sulphuric acids will at once detect the fraud.

Uses.—The rind of the lemon is sometimes used to qualify the taste and increase the power of stomacheic infusions and tinctures. The juice is refrigerant, and, properly diluted, forms a refreshing and agreeable beverage in febrile and inflammatory affections. It may be given with sweetened water in the shape of lemonade, or may be added to the mildly nutritive drinks, such as gum water, barley water, etc., usually administered in fevers. It is also much employed in the formation of those diaphoretic preparations known by the names of *neutral mixture* and *effervescent draught*. (See *Mistura Potassii Citratis*, 1880.) One of the most beneficial applications of lemon juice is to the prevention and cure of *scurvy*, for which it may be considered almost a specific. For this purpose, ships destined for long voyages should always be provided with a supply of the concentrated juice. In England every foreign-going ship is required by law to take such a supply of lemon juice that every seaman shall have a daily allowance of an ounce after having been ten days at sea. It has been employed with advantage in *acute rheumatism* in doses of from one to four fluidounces (30 to 120 Ce.) from four to six times a day. It has been used with benefit as a local application in *pruritus of the scrotum*, in *uterine hemorrhage* after delivery, in *sunburn*,¹ and as a gargle in *diphtheritic sore throat*.

LINIMENTA.

LINIMENTS

(lin-i-mén'tà)

Embrocations; Liniments, Embrocations, *Fr.*; Linimenta, Linimente, Einreibungen, *G.*

¹ An excellent formula for this purpose is: glycerin and lemon juice, each, a fluidounce, bismuth subnitrate a drachm; apply freely to the affected parts.

These are preparations intended for external use, of such a consistence as to render them conveniently applicable to the skin by gentle friction with the hand. The preparations official in the U. S. P. 1880 belonging to this class which were omitted in the 1890 edition of the U. S. Pharmacopœia were the *Liniments of Cantharides* and *Subacetate of Lead*. The U. S. P. (8th Rev.) retained all of those official in the previous edition excepting the *Linimentum Sinapis Compositum*.

LINIMENTUM ACONITI. Br.

LINIMENT OF ACONITE

(lin-i-mén'tum äc-q-ní'ti)

Liniment d'Aconit, *Fr.*; Akontitliniment, *G.*

"Aconite Root, in No. 40 powder, 20 ounces (Imperial) or 500 grammes; Camphor, 1 ounce (Imp.) or 25 grammes; Alcohol (90 per cent.), a sufficient quantity. Mix the powdered Aconite Root with twenty fluid ounces (Imp. meas.) or five hundred cubic centimetres of the Alcohol; set aside in a closed vessel for three days, agitating occasionally; transfer to a percolator; when the liquid ceases to pass, continue the percolation with more of the Alcohol, allowing the liquid to drop into a receiver containing the Camphor, until thirty fluid ounces (Imp. meas.) or seven hundred and fifty cubic centimetres of the liniment are produced." *Br.*

The British preparation is simply a very strong tincture of aconite root and camphor; that of the U. S. P. 1870² was almost equivalent to a fluidextract of aconite. Either may be applied alone by means of a camel's-hair pencil, or in connection with two parts or more of soap liniment or chloroform liniment, by rubbing it on the part affected. Experiments made by W. Donovan with a tincture prepared by macerating the fresh root, sliced, in rectified spirit for only twenty-four hours, proved that the preparation thus made, though acting in the same way, was much more powerful than the official (*Br.*). (*P. J.*, 2d ser., vi. 57.) The inference is that the fresh root should be used in preparing this liniment, and that a simple maceration is all that is required. There is a great waste both of aconite and of spirit in the process, as no provision is made, either by displacement with water or by expression, to separate from the mass in the percolator the strongly impregnated spirit retained in it. According to J. T. Porter, it requires twenty-eight parts, by measure, for every sixteen parts, by weight, of the dry root. On expressing the

² *Linimentum Aconiti*, U. S. 1870.—"Take of Aconite Root, in fine powder, eight troyounces; Glycerin a fluidounce; Alcohol a sufficient quantity. Moisten the powder with four fluidounces of Alcohol, and let it macerate for twenty-four hours; then pack it in a conical percolator, and gradually pour Alcohol upon it until two pints of tincture have been obtained. Distill off a pint and a half of alcohol, and evaporate the remainder until it measures seven fluidounces; to this add the Glycerin, and mix them thoroughly." *U. S.* 1870.

mare the loss of spirit was reduced to from 6 to 12 per cent. (*Ibid.*, xi. 66.) It is to be regretted that percolation to exhaustion and partial evaporation were not directed, as in the U. S. process for fluidextracts.

LINIMENTUM AMMONIÆ. U. S., Br.

AMMONIA LINIMENT [Volatile Liniment]

(lîn-j-mên'tûm am-mô'nî-æ)

Liniment of Ammonia, Linimentum volatile, Linimentum ammoniacale; Liniment ammoniacal (volatil), *Fr. Cod.*; Savon ammoniacal, *Fr.*; Linimentum Ammoniatum, *P. G.*; Flüchtiges Liniment, Flüchtige Salbe, *G.*; Linimento ammoniacale, *It.*; Linimento ammoniacal, *Sp.*

* "Ammonia Water, three hundred and fifty cubic centimeters [or 11 fluidounces, 401 minims]; Alcohol, fifty cubic centimeters [or 1 fluidounce, 331 minims]; Cotton Seed Oil, five hundred and seventy cubic centimeters [or 19 fluidounces, 131 minims]; Oleic Acid, thirty cubic centimeters [or 1 fluidounce, 7 minims], to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix them by agitation in a bottle, which should be well stoppered. This Liniment should be freshly prepared, when wanted." *U. S.* "Solution of Ammonia, 1 fl. ounce (Imperial measure) or 25 cubic centimetres; Almond Oil, 1 fl. ounce (Imp. meas.) or 25 cubic centimetres; Olive Oil, 2 fl. ounces (Imp. meas.) or 50 cubic centimetres. Shake together." *Br.*

The process of the U. S. Pharmacopœia differs from that of the U. S. P. 1870 not only in the proportion of ammonia water, which has been slightly reduced, but in the substitution of cotton seed oil for olive oil. The addition of 5 per cent. of alcohol prevents immediate separation, renders the mixture more uniform, and aids materially in binding together the oily and aqueous constituents, while the oleic acid aids still more in this direction. A liniment is now furnished which is liquid at ordinary temperatures. The ammonia liniment of the U. S. P. 1870 was usually solid and unmanageable. While complete saponification is not a desideratum in this liniment, a better oil than cotton seed oil is pure lard oil, which will form a white, smooth mixture.

The U. S. and British Pharmacopœias agree at present very nearly in the strength of this liniment, the U. S. preparation being somewhat the stronger. In the process, the ammonia reacts with the oil to form a soap, which is partly dissolved, partly suspended in the water, producing a white, opaque emulsion. The liniment is an excellent rubefacient, frequently employed in inflammatory affections of the throat, in catarrhal and other pectoral complaints of children, and in rheumatic pains. It is applied by rubbing it, or placing a piece of flannel saturated with it, over the affected part. Should it occasion too much inflammation, it must be diluted with oil.

LINIMENTUM BELLADONNÆ.

U. S., Br.

BELLADONNA LINIMENT

(lîn-j-mên'tûm bël-lă-dôn'næ)

Liniment of Belladonna; Liniment de Belladone, *Fr.*; Belladonnaliniment, *G.*

* "Camphor, fifty grammes [or 1 ounce av., 334 grains]; Fluidextract of Belladonna Root, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Dissolve the Camphor in about eight hundred cubic centimeters [or 27 fluidounces, 24 minims] of the Fluidextract, and then add enough of the latter to make the product measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." *U. S.*

"Liquid Extract of Belladonna, 10 fl. ounces (Imperial measure) or 250 cubic centimetres; Camphor, 1 ounce (Imp.) or 25 grammes; Distilled Water, 2 fl. ounces (Imp. meas.) or 50 cubic centimetres; Alcohol (90 per cent.), a sufficient quantity. Dissolve the Camphor in six fluid ounces (Imp. meas.) or one hundred and fifty cubic centimetres of the Alcohol; add the Liquid Extract of Belladonna, the Distilled Water, and sufficient of the Alcohol to produce twenty fluid ounces (Imp. meas.) or five hundred cubic centimetres of the Liniment. Set aside for twenty-four hours; filter." *Br.* The process for this liniment in both Pharmacopœias has been improved by using an assayed fluidextract. It affords a valuable means of applying belladonna externally.

LINIMENTUM CALCIS. U. S., Br.

LIME LINIMENT [Carron Oil]

(lîn-j-mên'tûm cāl'cîs)

Liniment of Lime; Liniment calcaire, *Fr. Cod.*; Savon calcaire, *Fr.*; Kalkliniment, *G.*; Linimento de calce, *It.*; Linimento Oleo-calcareo, *Sp.*

* "Lime Water, five hundred cubic centimeters [or 16 fluidounces, 435 minims]; Linseed Oil, five hundred cubic centimeters [or 16 fluidounces, 435 minims], to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix them by agitation." *U. S.* "Solution of Lime, 2 fl. ounces (Imperial measure) or 50 cubic centimetres; Olive Oil, 2 fl. ounces (Imp. meas.) or 50 cubic centimetres. Shake together." *Br.*

The lime forms a soap with the oil, of which there is a great excess, that separates upon standing. Olive oil, as directed by the British Pharmacopœia, is often substituted for that of flaxseed, which was originally used, but it possesses no other advantage than that of having a less unpleasant odor. The use of cotton seed oil in the U. S. P. 1880 did not meet the expectations of those who proposed it, and the U. S. P. 1890 reinstated linseed oil. This is a very useful application in recent burns and scalds, when smeared thickly upon lint or cotton

batting. It is sometimes called *Carron oil*, from having been much employed at the Carron iron works in Scotland.

LINIMENTUM CAMPHORÆ. U. S., Br.

CAMPBOR LINIMENT

(lin-j-mén'tüm cãm'pho-ræ)

Liniment of Camphor, Linimentum Camphoratum; Huile camphrée, *Fr. Cod.*; Liniment camphré, *Fr.*; Kampherliniment, Kampheröl, *G.*

* "Camphor, in coarse powder, two hundred grammes [or 7 ounces av., 24 grains]; Cotton Seed Oil, eight hundred grammes [or 28 ounces av., 96 grains], to make one thousand grammes [or about two pints]. Introduce the Camphor and the Cotton Seed Oil into a suitable flask, and apply a gentle heat, by means of a water-bath, loosely stoppering the flask during the operation. Agitate the flask occasionally, until the Camphor is dissolved." *U. S.*

"Camphor, in flowers, 1 ounce (Imperial) or 20 grammes; Olive Oil, 4 fl. ounces (Imp. meas.) or 80 cubic centimetres. Dissolve the Camphor in the Olive Oil." *Br.*

S. D. Wetterstroem prefers cold solution to the official method, thus avoiding any loss of camphor. (*West. Drug.*, 1897, 68.) This liniment is employed as an anodyne embrocation in sprains, bruises, rheumatic or gouty affections of the joints, and other local pains. It is also supposed to have a disiclient effect when rubbed upon glandular swellings. J. Weichselbaum has found camphor liniment to be a specific for the itching produced by cowhage. (*A. J. P.*, xlii. 519.) Camphor liniment should not be confounded with camphorated oil of the German Pharmacopœia which is much weaker (1 in 10). (See *Camphora*, page 274.) For methods of assaying camphor liniment see *C. D.*, 1900, 338; *P. J.*, 1898, 545; *P. J.*, 1902, 106; *Am. Drug.* 1905, 345.

Off. Prep.—Ceratum Camphoræ, *U. S.*; Linimentum Chloroformi, *Br.*; Linimentum Hydrargyri, *Br.*; Linimentum Terebinthinæ Aceticum, *Br.*

LINIMENTUM CAMPHORÆ AMMONIATUM. Br.

AMMONIATED LINIMENT OF CAMPHOR

(lin-j-mén'tüm cãm'pho-ræ âm-mo-ni'ä-tüm)

Compound Liniment of Camphor, *Br.*; Liniment ammoniacal camphré, *Fr. Cod.*; Linimentum ammoniato-camphoratum, *P. G.*; Flüchtiges Kampherliniment, Ammoniak- und Kampher-Liniment, *G.*; Linimento ammoniacale canforato, *It.*; Linimento amoniacal alcanforado; *Sp.*

"Camphor, 2½ ounces (Imperial) or 50 grammes; Oil of Lavender, 1 fl. drachm (Imp. meas.) or 2.5 cubic centimetres; Strong Solution of Ammonia, 5 fl. ounces (Imp. meas.) or 100 cubic centimetres; Alcohol (90 per cent.), a sufficient quantity. Dissolve the Camphor

and Oil of Lavender in twelve fluid ounces (Imp. meas.) or two hundred and forty cubic centimetres of the Alcohol; add the Strong Solution of Ammonia gradually, shaking them together until, after adding sufficient of the Alcohol to produce twenty fluid ounces (Imp. meas.) or four hundred cubic centimetres of the Liniment, a clear solution is formed." *Br.*

This is used as a rubefacient and at the same time anodyne embrocation in local pains, particularly of a rheumatic character.

LINIMENTUM CHLOROFORMI. U. S., Br.

CHLOROFORM LINIMENT

(lin-j-mén'tüm chlō-rō-fōr'mi)

Liniment of Chloroform; Liniment au Chloroforme, *Fr. Cod.*; Chloroformliniment, *G.*

* "Chloroform, three hundred cubic centimeters [or 10 fluidounces, 69 minims]; Soap Liniment, seven hundred cubic centimeters [or 23 fluidounces, 321 minims], to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix them by agitation." *U. S.*

"Chloroform, 2 fl. ounces (Imperial measure) or 50 cubic centimetres; Liniment of Camphor, 2 fl. ounces (Imp. meas.) or 50 cubic centimetres. Mix." *Br.*

A very great improvement was made in this preparation by the Committee of Revision of 1880, in the substitution of soap liniment for the olive oil. This change had been proposed in a previous edition of the Dispensatory, and it was desirable on account of the greasy residue which was left on the skin by the old preparation. The British Pharmacopœia has retained the oily vehicle. This is an excellent local application in painful affections. As the chloroform rapidly evaporates, it is desirable, in order to obtain its full anodyne effect, to guard against this by using waxed paper, or some other impermeable covering.

LINIMENTUM CROTONIS. Br.

LINIMENT OF CROTON OIL

(lin-j-mén'tüm cro-tō'nis)

Liniment crotoné, *Fr.*; Krotonöliniment, *G.*

"Croton Oil, 1 fl. ounce (Imperial measure) or 20 cubic centimetres; Oil of Cajuput, 3½ fl. ounces (Imp. meas.) or 70 cubic centimetres; Alcohol (90 per cent.), 3½ fl. ounces (Imp. meas.) or 70 cubic centimetres. Mix." *Br.*

This is a pustulating preparation, the irritant influence of which has been increased by the substitution of the oil of cajuput and the alcohol for the olive oil of the original formula. From ten to thirty minims (0.6 to 1.9 Cc.) or more may be rubbed upon a limited surface, and repeated twice a day or oftener until an eruption is produced.

LINIMENTUM HYDRARGYRI. Br.

LINIMENT OF MERCURY

(lín-j-mén'tüm hy-drär'gy-rí)

Linimentum Mercuriale; Liniment mercuriel, *Fr.*; Quecksilberliniment, *G.*

"Ointment of Mercury, 1 ounce (Imperial) or 30 grammes; Strong Solution of Ammonia, 160 minims (Imp. meas.) or 10 cubic centimetres; Liniment of Camphor, a sufficient quantity. Add the Strong Solution of Ammonia to sufficient of the Liniment of Camphor to produce one fluid ounce and a half (Imp. meas.) or forty-five cubic centimetres; triturate the Ointment of Mercury with sufficient of the Liniment of Camphor to produce one fluid ounce and a half (Imp. meas.) or forty-five cubic centimetres; mix the two liquids." *Br.*

This is a stimulating liniment, employed for the discussion of chronic glandular enlargements, swellings of the joints, and venereal tumors, and to promote the absorption of fluid. It is said to be more likely to salivate than is mercurial ointment. One fluidrachm (3.7 Cc.) may be rubbed upon the affected part night and morning. It should be thoroughly agitated before being applied.

LINIMENTUM OPII. Br.

LINIMENT OF OPIUM

(lín-j-mén'tüm ô'pí-i)

Anodyne Liniment; Liniment opiacé, *Fr.*; Oplum-Liniment, *G.*

"Tincture of Opium, 2 fl. ounces (Imperial measure) or 50 cubic centimetres; Liniment of Soap, 2 fl. ounces (Imp. meas.) or 50 cubic centimetres. Mix; set aside for a few days; filter." *Br.*

This is commonly called *anodyne liniment*, and is employed as an anodyne and gently rubefacient embrocation in sprains, bruises, and rheumatic or gouty pains. We are informed that the preparation which has been commonly used under the name of *anodyne liniment* is that of the late London Pharmacopœia, as given in former editions of the U. S. Dispensatory, consisting of one part by measure of tincture of opium and three parts of soap liniment, and consequently having only half the opiate strength of the present British liniment.

LINIMENTUM POTASSII IODIDI CUM SAPONE. Br.

LINIMENT OF POTASSIUM IODIDE WITH SOAP

(lín-j-mén'tüm pò-tàs'sí-i í-ôd'í-dí cüm sà-pó'ně)

Liniment savonneux ioduré, *Fr.*; Jodkallium-Seifen-Liniment, *G.*

"Curd Soap, recently prepared and in shavings, 2 ounces (Imperial) or 40 grammes; Potassium Iodide, 1½ ounces (Imp.) or 30

grammes; Glycerin, 1 fl. ounce (Imp. meas.) or 20 cubic centimetres; Oil of Lemon, 1 fl. drachm (Imp. meas.) or 2.5 cubic centimetres; Distilled Water, 10 fl. ounces (Imp. meas.) or 200 cubic centimetres. Reduce the Curd Soap to fine shreds; mix it with the Distilled Water and Glycerin in a porcelain dish on a water-bath; when the Soap is dissolved, pour the liquid into a mortar in which the Potassium Iodide has previously been powdered; mix briskly by trituration; continue the trituration until the mixture is cold; set aside for an hour; then rub well the Oil of Lemon into the cream-like product." *Br.*

This preparation is apparently intended, by application to the surface, which may be attended with a gentle friction, to produce the absorption of the iodide, and thus to obtain its alterative and deobstruent effects through the circulation. The soap and glycerin act as demulcents, and thus obviate in some measure the local irritation of the salt.¹

LINIMENTUM SAPONIS. U. S., Br.

SOAP LINIMENT

(lín-j-mén'tüm sà-pó'nís)

Tinctura Saponis Camphorata, *U. S.* 1850; Spiritus Nervinus Camphoratus; Liquid Opodeldoc; Camphorated Tincture of Soap; Liniment savonneux camphré, *Fr.*; Linimentum saponato camphoratum, *P. G.*; Flüssiger Opodeldok, *G.*; Linimento di sapone con canfora, *It.*

* "Soap, dried and granulated, sixty grammes [or 2 ounces av., 51 grains]; Camphor, in small pieces, forty-five grammes [or 1 ounce av., 257 grains]; Oil of Rosemary, ten cubic centimeters [or 162 minims]; Alcohol, seven hundred and twenty-five cubic centimeters [or 24 fluidounces, 247 minims]; Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Add the Soap to two hundred cubic centimeters [or 6 fluidounces, 366 minims] of boiling Water, heat the mixture on a water-bath until a clear gelatinous mass results. Mix this, while

¹ It seems to have been clearly established by the discussion carried on in *P. J.*, 2d ser., xi., that Castile soap, and even individual brands of soap, vary so much that it is impossible to get uniform results from the former official process, the preparation sometimes being beautifully transparent and jelly-like, at other times opaque and ointment-like. Various remedies were proposed, but finally N. Smith called attention to the fact that the formula adopted by the reviewers of the Pharmacopœia differs from the original one of Rumsey. This Smith states to be as follows: "Take of White Curd Soap (made from Russian tallow) two ounces; Potassium Iodide one ounce and a half; Glycerin one ounce; Distilled Water ten ounces; Essential Oil of Lemon one drachm. Reduce the Soap into fine shreds, and melt in a water-bath, with the whole of the Water and the Glycerin; when the Soap is perfectly dissolved, pour it into a No. 9 Wedgwood mortar in which the potassium iodide has been previously reduced to fine powder; mix briskly, and continue the trituration until the mortar has become cool and the liniment assumes the character of ice-cream. Set aside for an hour, after which gently rub in the Oil of Lemon." It will be noticed that Rumsey's process has been practically adopted by the present British Pharmacopœia.

yet warm, with five hundred cubic centimeters [or 16 fluidounces, 435 minims] of Alcohol, and stir it until solution is effected. Dissolve the Camphor and Oil of Rosemary in two hundred and twenty-five cubic centimeters [or 7 fluidounces, 292 minims] of the Alcohol by agitation in a bottle; add this solution to the warm Soap mixture; mix thoroughly, and, if necessary, add enough Water to make the product measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Set it aside in a cool place for twenty-four hours, then filter." U. S.

"Soft Soap, 2 ounces (Imperial) or 40 grammes; Camphor, 1 ounce (Imp.) or 20 grammes; Oil of Rosemary, 3 fl. drachms (Imp. meas.) or 7.5 cubic centimetres; Alcohol (90 per cent.), 16 fl. ounces (Imp. meas.) or 320 cubic centimetres; Distilled Water, 4 fl. ounces (Imp. meas.) or 80 cubic centimetres. Dissolve the Soap in the Distilled Water; dissolve the Camphor and Oil of Rosemary in the Alcohol; mix the solutions; set aside for one week; filter." Br.

This process is intended to furnish a saturated solution of Castile soap. The recommendation in the 16th edition of this Dispensatory, that granulated soap be used in preference to soap in shavings in this liniment, was adopted by the U. S. Pharmacopœia Eighth Revision, for powdered soap does not vary greatly in the proportion of water left in it; the process is one recommended by Geo. W. Sloan of Indianapolis, and if all the details are carefully followed it is a great improvement over that of the U. S. Pharmacopœia 1880. The improvement was made in the last revision of the U. S. P. of making a gelatinous mass of the soap by adding it to sufficient boiling water and heating it until dissolved; the soft mass easily dissolves in the alcoholic solution of the oils. The British preparation is now made with soft (potash) soap; this method was recommended by J. T. Hornblower. ("C. D., 1894, 571.) The liniment is said to be made more quickly and precipitation is avoided. In 1859 Dean showed that sodium oleate is freely soluble in alcohol, while the palmitate is nearly insoluble, consequently the latter salt is left behind in the old British process. Although olive oil contains a large percentage of olein, yet it has been proposed to substitute almond oil,¹ for it is still richer. The economy of this is, however, very doubtful. Castor oil has also been suggested. (A. J. P., xlv. 529.) G. W. Berekhausen states that the potassa soaps are perfectly soluble in alcohol, and suggests rape seed oil as a good base. (A. J. P., 1873, p. 17.)

In former editions of the U. S. Pharmacopœia, this preparation, though commonly called *Soap Liniment*, received the name of *Tinctura Saponis Camphorata*, to distinguish it from a

similar preparation called *opodeldoc*, which, having a soft semi-solid consistence, held the title *Linimentum Saponis Camphoratum*.²

Soap liniment is much used, as an anodyne and gently rubefacient embrocation, in sprains, bruises, and rheumatic or gouty pains.

Off. Prep.—Linimentum Chloroformi, U. S.; Linimentum Opii, Br.

LINIMENTUM SAPONIS MOLLIS. U. S.

LINIMENT OF SOFT SOAP [Tincture of Green Soap]

(lîn-i-mên'tûm sâ-pô'nis mô'll'is)

Tincturâ Saponis Viridis, U. S. P. 1880; Spiritus Saponis Kalinal Hebra; Tainture de Savon vert, Fr.; Hebra's Seltenspiritus, G.

* "Soft Soap, six hundred and fifty grammes [or 22 ounces av., 406 grains]; Oil of Lavender Flowers, twenty cubic centimeters [or 325 minims]; Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix the Oil of Lavender Flowers with three hundred cubic centimeters [or 10 fluidounces, 69 minims] of Alcohol, dissolve in this the Soft Soap by stirring or agitation, and set the solution aside for twenty-four hours. Then filter it through paper, adding sufficient alcohol to make the product measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." U. S.

This is the *tincture of green soap* of Hebra under a new name; it should never have been called *Tinctura Saponis Viridis*, as it belongs clearly in the class of liniments and is always used externally. C. E. Smith suggested the preparation of this liniment from the fixed oil directly, which has the advantage of convenience as well as of greater uniformity of strength.³ If a green color is desirable in this

² *Opodeldoc*.—"Take of Common Soap, sliced, three ounces; Camphor an ounce; Oil of Rosemary, Oil of Origanum, each, a fluidrachm; Alcohol a pint. Digest the Soap with the Alcohol, by means of a sand-bath, till dissolved; then add the Camphor and Oils, and, when they are dissolved, pour the liquid into broad-mouthed bottles. This liniment has, when cold, the consistence of a soft ointment." U. S. P. 1850.

This preparation differs from the official *Linimentum Saponis* chiefly in being prepared with common white soap, made with animal fat, instead of Castile soap, which is made of olive oil. The former is peculiarly adapted to the purposes of this formula, in consequence of assuming, when its alcoholic solution cools, the consistence characteristic of the liniment. It is customary after the solution of the soap has been effected to pour the liquid into small wide-mouthed glass bottles, containing about four fluidounces, in which it concretes into a soft, translucent, uniform, yellowish-white mass. This liniment melts with the heat of the body.

³ *Liniment of Soft Soap*.—Dissolve 75 Gm. potassium hydroxide in 200 Cc. of water, put the solution in a bottle of about 1500 Cc. capacity, add 325 Gm. linseed oil and 300 Cc. alcohol, and shake the mixture briskly for some time, until there is no further separation of oil on standing. Let the solution stand in a moderately warm place for twenty-four (to forty-eight) hours, then dissolve in it 20 Cc. oil of lavender, add enough water to make the product measure 1000 Cc., mix and filter. The process is easily finished in ten days, the main precaution to be observed being that the potassium hydroxide be neither stronger nor weaker than 90 per cent., unless allowance be made for difference in strength. Refined cotton-seed oil or olive oil may be used instead

¹ A formula for making almond oil soap on the small scale may be found in P. J., 2d ser., xl. 417.

preparation, it may be obtained by using hemp seed oil or Malaga olive oil (see *Proc. A. Ph. A.*, 1903, 420).

LINIMENTUM SINAPIS. Br.

LINIMENT OF MUSTARD

(lîn-î-mên'tûm sî-nă'pîs)

Liniment Sinapsé composé, *Fr.*; Zusammengesetztes Senfliniment, *Senfliniment*, *G.*

"Volatile Oil of Mustard, 1½ fl. drachms (Imperial measure) or 2 cubic centimetres; Camphor, 120 grains (Imp.) or 3 grammes; Castor Oil, 5 fl. drachms (Imp. meas.) or 7 cubic centimetres; Alcohol (90 per cent.), 4 fl. ounces (Imp. meas.) or 43 cubic centimetres. Dissolve the Camphor in the Alcohol; add the Oil of Mustard and Castor Oil; mix." *Br.*

This preparation, which was dropped from the U. S. P. (8th Rev.), may be made by the U. S. P. 1890 process;¹ it affords a convenient method of applying the volatile oil of mustard, and may often be appropriately used as a substitute for sinapisms. The extract of mezereon is also a very energetic irritant. The castor oil seems to be added in order to increase somewhat the consistence of the liniment, and was probably chosen from among oleaginous substances in consequence of its solubility in alcohol. The effect is increased if the liniment be applied on flannel, and volatilization guarded against by covering it with oiled silk. For the circumstances calling for the use of this liniment, see *Sinapis*.

LINIMENTUM TEREBINTHINÆ.

U. S., Br.

TURPENTINE LINIMENT

(lîn-î-mên'tûm tēr-ē-bin'thî-næ)

Linimentum Terebinthinatum; Liniment of Turpentine; Liniment térébenthiné, *Fr.*; Terpentinliniment, *G.*

* "Rosin Cerate, six hundred and fifty grammes [or 22 ounces av., 406 grains]; Oil of Turpentine, three hundred and fifty grammes [or 12 ounces av., 151 grains], to make one thousand grammes [or 35 ounces av., 120

grains]. Dissolve the Rosin Cerate, previously melted in a dish on a water-bath, in the Oil of Turpentine, and mix them thoroughly." *U. S.*

"Soft Soap, 1½ ounces (Imperial) or 37.5 grammes; Distilled Water, 5 fl. ounces (Imp. meas.) or 125 cubic centimetres or a sufficient quantity; Camphor, 1 ounce (Imp.) or 25 grammes; Oil of Turpentine, 13 fl. ounces (Imp. meas.) or 325 cubic centimetres. Mix the Soft Soap with two fluid ounces (Imp. meas.) or fifty cubic centimetres of the Distilled Water; dissolve the Camphor in the Oil of Turpentine; gradually add the latter solution to the former, triturating until the mixture becomes a thick creamy emulsion; lastly mix with sufficient Distilled Water to produce one pint (Imp. meas.) or five hundred cubic centimetres." *Br.*

The U. S. preparation is the liniment originally proposed by Kentish, and subsequently so highly lauded as a remedy in burns and scalds. It should be applied as soon after the occurrence of the accident as possible, and should be discontinued when the peculiar inflammation excited by the fire is removed. The best mode of application is to cover the burnt or scalded surface with pledgets of patent lint saturated with the liniment. It should not be allowed to come in contact with the sound parts. This liniment may also be successfully applied in other cases of cutaneous inflammation requiring stimulation, as in certain conditions of *erysipelas*. The present British preparation, so far as regards its rubefacient operation, may be looked upon as almost undiluted oil of turpentine, the soft soap having little other effect than to give consistence to the liniment, and the camphor acting as an anodyne, and both being too small in bulk to dilute the oil materially. It is a very ineligible and variable preparation.

LINIMENTUM TEREBINTHINÆ ACETICUM. Br.

LINIMENT OF TURPENTINE AND ACETIC ACID

(lîn-î-mên'tûm tēr-ē-bin'thî-næ ā-cēt'î-cûm)

Linimentum Album; Acetic Turpentine Liniment, Stokes' Liniment; Liniment térébenthiné acétique, *Fr.*; Terpentin- und Essig-liniment, *G.*

"Oil of Turpentine, 4 fl. ounces (Imperial measure) or 100 cubic centimetres; Glacial Acetic Acid, 1 ounce (Imp.) or 25 grammes; Liniment of Camphor, 4 fl. ounces (Imp. meas.) or 100 cubic centimetres. Mix." *Br.*

This is a powerful rubefacient liniment, combining the irritant properties of the oil of turpentine and acetic acid, though somewhat diluted by the camphor liniment.¹ Glacial acetic acid was substituted for acetic acid in the 1885

of linseed oil without changing the proportion of potassium hydroxide, but these oils usually produce a liniment of lighter color than would be obtained from linseed oil. (*A. J. P.*, 1896, 187.)

¹ *Linimentum Sinapis Compositum*. Compound Liniment of Mustard.—"Volatile Oil of Mustard, thirty cubic centimetres [or 1 fluidounce, 7 minims]; Fluid Extract of Mezereum, two hundred cubic centimetres [or 6 fluidounces, 386 minims]; Camphor, sixty grammes [or 2 ounces av., 51 grains]; Castor Oil, one hundred and fifty cubic centimetres [or 5 fluidounces, 35 minims]; Alcohol, a sufficient quantity, to make one thousand cubic centimetres [or 33 fluidounces, 390 minims]. Dissolve the Camphor in five hundred cubic centimetres [or 16 fluidounces, 435 minims] of Alcohol, and add the Fluid Extract of Mezereum; then add the Oil of Mustard and the Castor Oil, and, finally, enough Alcohol to make the product measure one thousand cubic centimetres [or 33 fluidounces, 390 minims]. Mix thoroughly." *U. S.* 1890.

¹ *St. John Long's Liniment*.—Under this name a liniment is often used which is made as follows: "Take the yolk of one egg, 5 fluidrachms of Acetic Acid, 3 fluidounces of Oil of Turpentine, 2½ fluidounces of Rose Water, and ½ fluidrachm of Oil of Lemon. Make an emulsion."

revision in equivalent proportion; the change is an improvement pharmaceutically, as it now affords a clear solution.

LINUM CONTUSUM. Br.

CRUSHED FLAXSEED

(Lī'nūm cōn-tū'sūm)

"Linseed reduced to a coarse powder." Br.

Linum usitatissimum, Willd., *Sp. Plant.* i. 1533; B. & T. 39.—Common flax is an annual plant, with an erect, slender, round stem, about two feet in height, branching at top, and, like all other parts of the plant, entirely smooth. The leaves are small, lanceolate, acute, entire, of a pale-green color, sessile, and scattered alternately over the stem and branches. The flowers are terminal, and of a delicate-blue color. The calyx is persistent, and composed of five ovate, sharp-pointed, three-nerved leaflets, which are membranous on their border. The petals are five, obovate, striated, minutely scalloped at their extremities, and spread into funnel-shaped blossoms. The filaments are also five, united at the base, and the germ, which is ovate, supports five slender styles, terminating in obtuse stigmas. The fruit is a globular capsule, about the size of a small pea, having the persistent calyx at the base, crowned with a sharp spine, and containing ten seeds in distinct cells. This highly valuable plant, now almost everywhere cultivated, is said by some to have been originally derived from Egypt, by others from the great elevated plain of Central Asia. It flowers in June and July, and ripens its seed in August.¹

The seeds are oval, oblong, flattened on both sides, with acute edges, somewhat pointed at

one end, one to two lines in length, smooth, glossy, brown externally, and yellowish white within, "ovate or oblong-lanceolate, flattened, 4 or 5 Mm. long, obliquely pointed at one end; externally chestnut-brown, very smooth and glossy, covered with a transparent, mucilaginous outer wall which swells in water; embryo whitish or greenish, with two large, plano-convex and oily cotyledons, embedded in a thin perisperm; odor slight; taste mucilaginous, oily." U. S. They are inodorous, and have an oily mucilaginous taste. Meyer found in them fixed oil, wax, resin, extractive, tannin, gum, nitrogenous mucilage, starch, albumen, gluten, and various salts. Meurein could find no starch, but detected phosphates, which had escaped the notice of Meyer. (*J. P. C.*, 3e sér., xx. 97.) Their investing coat abounds in a peculiar gummy matter or mucilage, which is readily imparted to hot water, forming a thick viscid fluid, that lets fall white flakes upon the addition of alcohol, and affords a copious dense precipitate with lead subacetate. The viscid mucilage of linseed cannot be filtered until it has been boiled. It contains in the dry state more than 10 per cent. of mineral substances; when freed from these and dried at 110° C., it corresponds, like althæa mucilage, to the formula $C_{12}H_{20}O_{10}$. The seeds by exhaustion with cold or warm water afford of it about 15 per cent. By boiling with nitric acid, it yields crystals of mucic acid; by diluted mineral acids, it is broken up into dextrogyrate gum, sugar, and cellulose. (Kirchner and Tollens, *Ann. Ch. Ph.*, 175, 215.)

Jorissen and Hairs (*Drogues Simples*, t. ii. 685) obtained from the young plant a glucoside, to which they gave the name of *linamarin*, which crystallizes in colorless needles, melting at 134° C., without odor, but possesses a fresh and bitter taste. It differs from amygdalin in not being decomposed by emulsin, but diluted acids decompose it into sugar, hydrocyanic acid, and a third product which is volatile and possesses certain of the characters of the acetones. No benzaldehyde is formed. Linseed contains about 4 per cent. of nitrogen, corresponding to about 25 per cent. of proteid substances. After expression of the oil these substances remain in the cake, so that the latter contains 5 per cent. of nitrogen and constitutes a very important article for feeding cattle and is termed *cake meal*. In the ripe state linseed is altogether destitute of starch, though this substance is found in the immature seed in the very cells which subsequently yield the mucilage. The mucilage may be considered, as in analogous cases, to be a product of the transformation of starch. (Flückiger, *Pharmacographia*, 2d ed., p. 99.) The interior of the seed, or nucleus, is rich in a peculiar oil, which is separated by expression, and extensively employed in the arts on account of its drying properties. (See *Oleum Lini*.)

The ground seeds are found in commerce under the name of *flaxseed meal*. This is of a

¹ The linseeds in commerce have been divided by E. M. Holmes into two groups. The first group, characterized by the seeds being of sufficient size for six or seven to weigh a grain, contains Bombay, Bold Calcutta, Sicilian, and Ionian seed; in the group of small seeds (10 to 12 to the grain) are English, Dutch, Russian, and ordinary Calcutta varieties. An important practical point noticed by Holmes is that many of these seeds are apparently purposely adulterated with weed seeds, which are nearly always smaller than the linseeds, and can therefore be separated by the sieve. When linseed meal is to be made for medicinal use, this separation should always be insisted upon, as many of the weed seeds are from Cruciferae, and are irritating. For detailed information as to varieties of linseed, weed seeds, etc., the reader is referred to Holmes's paper. (*P. J.*, July, 1881; also *N. R.*, 1881.)

dark-gray color, highly oleaginous, and when mixed with hot water forms a soft adhesive mass, much employed for luting by practical chemists. "Ground Linseed (Linseed Meal or Flaxseed meal) should be recently prepared and free from unpleasant or rancid odor. It is a grayish-yellow powder containing brownish fragments, and when exhausted by carbon disulphide should yield not less than 30 per cent. of a fixed oil, all of which is saponifiable. If 0.1 Gm. of ground Linseed be mixed with 20 Cc. of water and the mixture heated to boiling, then cooled and diluted with cold water to 100 Cc., the addition of 0.5 Cc. of iodine T.S. should not produce more than a pale blue color (limit of starch)." U. S. The average composition of linseed oil cake is thus given by Schaedler (*Technologie der Fette und Oele*, 1883): moisture, 10.56 per cent.; oil, 9.83 per cent.; non-nitrogenous fibre, 44.61 per cent.; ash, 6.5 per cent.; proteid matter, 28.5 per cent. Much of the linseed meal of commerce is simply cake meal, which was, indeed, official in the former Br. Ph., but such meal is unfit for medicinal use, not only because it contains very little oil, but also because the oil which is in it has, through rupture of the cells and partial expression, been so exposed to the air as to become rancid. Linseed meal is sometimes adulterated with corn meal, or other meals containing starch, whose presence is at once revealed by the iodine test.¹ It is sometimes found in the market adulterated with petroleum or other mineral oil, doubtless made by powerfully pressing the pure linseed meal and substituting for the linseed oil the less expensive product, petroleum. (*A. J. P.*, 1902, 31.)

Uses.—Flaxseed is demulcent and emollient. The mucilage obtained by infusing the entire seeds in boiling water, in the proportion of half an ounce to the pint, is much and very advantageously employed in *catarrh, dysentery, nephritic and calculous complaints, strangury*, and other inflammatory affections of the mucous membrane of the lungs, intestines, and urinary passages. By decoction, water extracts a portion of the oleaginous matter, which renders the mucilage less fit for administration by the mouth, but superior as a laxative enema. The meal mixed with hot water forms an excellent emollient poultice.

¹ The value of a sample of crushed linseed can be absolutely determined only by analysis. It should contain from 25 to 35 per cent. of oil, not more than 8 or 8.5 per cent. of husk, and less than 8 per cent. of ash. The following test is said to be sufficient for practical purposes: "Put half an ounce of the meal into a glass vessel, pour six ounces of boiling water over it, stir well, and allow it to stand for twelve hours. If first-class, it should absorb all the water, and show a thin scum of white glutinous liquid on the top, which will adhere closely to a glass rod or a wooden pencil dipped into it. If the meal does not absorb nearly all the water, it is of inferior quality. The amount of inferiority must be judged by the amount of water not absorbed, and by the character of the fluid on the top of the solution. If it is thin and non-glutinous, the meal is of inferior quality."

LIQUOR ACIDI ARSENOSI. U. S. (Br.)

SOLUTION OF ARSENOUS ACID

(lī'quor āc'ī-di ār-se-nō'sī)

"An aqueous solution, which should contain Arsenous Acid corresponding in amount to 1 per cent. of arsenic trioxide [$\text{As}_2\text{O}_3 = 196.44$]." U. S.

Liquor Arsenici Hydrochloricus, Br.; **Liquor Arsenici Chloridi, U. S. P. 1870:** Hydrochloric Solution of Arsenic, *Soluté d'Acide Arsénieux, Fr. Cod.;* *Liquor de Boudin, Liqueur arsénicale hydrochlorique, Fr.;* *Chlorarsenik-Lösung, G.*

* "Arsenic Trioxide, *ten grammes* [or 154 grains]; Diluted Hydrochloric Acid, *fifty grammes* [or 1 ounce av., 334 grains]; Distilled Water, a sufficient quantity, to make *one thousand grammes* [or 35 ounces av., 120 grains]. Mix the Diluted Hydrochloric Acid with *two hundred and fifty grammes* [or 8 ounces av., 358 grains] of Distilled Water, in a tared porcelain dish, add the Arsenic Trioxide, and boil the mixture until the Arsenic Trioxide is dissolved. Then add enough Distilled Water to make the product weigh *one thousand grammes* [or 35 ounces., 120 grains]. Filter through paper." U. S.

"Arsenious Anhydride, in powder, $87\frac{1}{2}$ grains (Imperial) or 10 grammes; Hydrochloric acid, 2 fl. drachms (Imp. meas.) or 12.5 cubic centimetres; Distilled Water, a sufficient quantity. Heat the Arsenious Anhydride and the Hydrochloric Acid with *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of Distilled Water in a one-pint (or one-litre) flask until a clear solution is obtained; cool; add sufficient Distilled Water to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Solution." Br.

This solution is stronger than the *Liquor Arsenici Chloridi* of the U. S. P. 1870. It contains 4.5 grains of arsenous acid in a fluid-ounce; the U. S. P. 1870 preparation corresponded in strength with the old British solution (4 grains in a fluidounce). The increase in strength was made in order to make the relation one that would be easy to recollect, namely, 1 per cent. by weight, and the British Pharmacopœia has wisely followed the example, so that both preparations are practically identical. The name has also been changed, as the former title was a misnomer. The hydrochloric acid does not enter into combination with the arsenic trioxide; it merely aids in its solution. The British title is, in our opinion, to be preferred, because the U. S. name does not indicate the presence of the hydrochloric acid.

Properties.—The hydrochloric solution of arsenic trioxide was first recognized by the U. S. Pharmacopœia at the revision of 1870. According to the British Pharmacopœia, it is "a colorless liquid having an acid reaction. 25 cubic centimetres diluted with water should discharge the color of 50.8 to 50.9 cubic centimetres of the volumetric solution of iodine, the

presence of a slight excess of *sodium bicarbonate* being maintained throughout the operation." "110 minims contain 1 grain of Arsenious Anhydride; 100 cubic centimetres contain 1 gramme." *Br.* The following description and test is given in the U. S. P. (8th Rev.): "A clear, colorless liquid, odorless, having an acidulous taste and an acid reaction. If to 24.6 Gm. of Solution of Arsenous Acid about 2 Gm. of sodium bicarbonate and 100 Cc. of water be added, not less than 50 Cc. of tenth-normal iodine V.S. should be required to produce a permanent yellow tint (corresponding to 1 Gm. of arsenic trioxide in 100 Gm. of the Solution)." *U. S.*

Uses.—The medicinal properties of this solution are the same as those of Fowler's solution, with which it corresponds in strength, being nearly three times as strong as the former London solution of arsenic chloride.

Dose, from two to eight minims (0.12 to 0.5 Cc.).

LIQUOR ACIDI CHROMICI. Br.

SOLUTION OF CHROMIC ACID

(l'quor æç'i-dî çhrô'mî-ci)

Soluté d'Acide Chromique, *Fr. Cod.*; Chromsaurelösung, *G.*

"An aqueous solution containing the equivalent of 25 per cent. of Chromic Anhydride, CrO_3 ; or 29.5 per cent. of chromic acid regarded as H_2CrO_4 ." *Br.*

"Chromic Anhydride, 1 ounce (Imperial) or 25 grammes; Distilled Water, 3 fl. ounces (Imp. meas.) or 75 cubic centimetres. Dissolve." *Br.*

This is officially described as "an orange-red, inodorous, caustic, strongly acid liquid. Specific gravity 1.185. It should respond to the tests described under 'Acidum Chromicum.'" *Br.* It is simply a definite solution of chromic acid, and will probably be found convenient as a caustic application. (See *Chromii Trioxidum*, p. 334.) It is not used internally.

LIQUOR AMMONII ACETATIS.

U. S., Br.

SOLUTION OF AMMONIUM ACETATE

(Spirit of Mindererus)

(l'quor æm-mō-nî-i æç-ç-tā'tis)

"An aqueous solution which should contain not less than 7 percent. of Ammonium Acetate [$\text{CH}_3\text{COONH}_4 = 76.51$], with small amounts of acetic and carbonic acids." *U. S.*

Spiritus Mindereri; *Liquor Ammonia Acetatis*; *Acétate d'Ammoniaque liquide*, *Fr. Cod.*; *Esprit de Mindererus*, *Fr.*; *Liquor Ammonii Acetici*, *P. G.*; *Ammoniumacetatlösung*, *Essigsäure Ammoniumlösung*, *G.*

* "Ammonium Carbonate, five grammes [or 77 grains]; Diluted Acetic Acid, one hundred cubic centimeters [or 3 fluidounces, 183 min-

ims]. Add the Ammonium Carbonate (which should be in translucent pieces, free from white, pulverulent bicarbonate) gradually to the cold Diluted Acetic Acid, and stir until it is dissolved. This preparation should be freshly made when wanted." *U. S.*

"Ammonium Carbonate, 1 ounce (Imperial) or 50 grammes; Acetic Acid, Distilled Water, of each a sufficient quantity. Dissolve the Ammonium Carbonate in ten times its weight of Distilled Water; neutralize with Acetic Acid; add sufficient Distilled Water to produce one pint (Imp. meas.) or one thousand cubic centimetres of the Solution. A little of the Solution, heated in a test-tube to expel carbonic anhydride, should be neutral or only slightly acid to test-papers. Solution of Ammonium Acetate should be preserved in a green glass bottle." *Br.*

This preparation is an aqueous solution of ammonium acetate.¹ The U. S. process by which it is formed involves the decomposition of ammonium carbonate by diluted acetic acid. The formula of commercial ammonium carbonate is complex, but the reaction is expressed by the following equation:

Distilled vinegar was formerly used, but it has been abandoned for diluted acetic acid, which is much to be preferred, because, besides furnishing a solution of the acetate of uniform strength, a result which cannot be attained by the employment of distilled vinegar, it avoids the production of a brownish solution, which uniformly follows the use of the latter, especially when it has been condensed in a metallic worm. The quantity of ammonium carbonate necessary to saturate a given weight of the acid of average strength cannot be laid down with precision, on account of the variable quality of the salt. The preparation, when made with the diluted acetic acid of the U. S. Pharmacopoeia, contains about 7 per cent. of ammonium acetate. It is more convenient to add the salt to the acid than to add the acid to the salt, as the point of saturation is thus more easily attained. In ascertaining this point by test paper, the alkaline reaction will begin, though a portion of free acetic acid may still remain, a little of it being insufficient to overcome the natural alkaline reaction of the salt. A complication is caused by the presence of free carbon dioxide, which may be expelled from the liquid towards the end of the saturation by warming it. Supposing it to be free from carbon dioxide, the best rule is to cease adding the ammonium carbonate upon the occurrence of the least sign of alkalinity.

The formula of the U. S. P. 1890 differed from that formerly official in dropping what has been called the "mixed solution process,"

¹ For method of making dry ammonium acetate, see *A. J. P.*, 1875, 25. See also *A. J. P.*, 1902, 13.

and the U. S. P. (8th Rev.) has retained the 1890 process without change. It is to be regretted that the old process of saturating the diluted acetic acid with the ammonium carbonate was not entirely abandoned in the last revision and the process of mixing the solutions alone directed. The separate solutions keep well, and the rapidity and ease with which this preparation can be made by the pharmacist, by simply mixing equal measures of the solutions, are advantages which at once recommend its exclusive use, while the physician is more likely to secure a fresh preparation, and one which usually retains a quantity of carbon dioxide to render the preparation grateful to the patient.

As some pharmacists will prefer to make solution of ammonium acetate in this way, the following process, based on that of the U. S. P. 1880, is offered. Ammonium Carbonate, *one hundred grammes* [or 3 ounces av., 230 grains]; Acetic Acid, *two hundred and seventy cubic centimeters* [or 9 fluidounces, 62 minims]; Distilled Water, *one thousand seven hundred and thirty cubic centimeters* [or 58 fluidounces, 240 minims]. Dissolve the Ammonium Carbonate in *nine hundred and fifty cubic centimeters* [or 32 fluidounces, 60 minims] of Distilled Water, and filter the solution. To the Acetic Acid add *seven hundred and eighty cubic centimeters* [or 26 fluidounces, 180 minims] of Distilled Water. Keep the solutions in separate, well-stoppered bottles, and when solution of ammonium acetate is to be dispensed measure equal quantities of each solution and mix them.

The present British process does not differ essentially from ours; in the Br. Pharmacopœia of 1864 the strong solution of ammonia was used instead of the carbonate, and the ammonia combined directly with the acetic acid, without other reaction. There was an advantage in this process in the use of ammonia instead of its carbonate, as the difficulty of ascertaining the precise point of saturation arising from carbon dioxide was avoided, but in this solution, as in the neutral mixture, a great benefit remedially is gained by the presence of carbonic acid, which reconciles the stomach to the medicine, and sometimes even allays vomiting in febrile diseases. With this view of the subject it is better to use ammonium carbonate; the change has been made in the present Br. Pharmacopœia, but the advantages are practically lost because the solution is nearly always made in advance of actual use, and official solution of ammonium acetate is rarely sparkling, but as generally dispensed it has a flat, mawkish taste quite in contrast with that made by the "mixed solution process."

Properties.—Solution of ammonium acetate, when made of pure materials, is "a clear, colorless liquid, free from empyreuma, of a mildly saline, acidulous taste, and an acid reaction. It is wholly volatilized by heat. When Solution of Ammonium Acetate is heated with

potassium hydroxide T.S., ammonia is evolved. If to 5 Cc. of the Solution 1 Cc. each of sulphuric acid and alcohol be added, and the mixture boiled, the odor of acetic ether will be developed." *U. S.* When it contains an excess of alkali, its taste is bitterish. It should be freshly prepared at short intervals, as its acid becomes decomposed and a portion of ammonium carbonate is generated. When pure it is not precipitated by barium chloride. Silver nitrate precipitates crystals of silver acetate, soluble in water, and especially in nitric acid. An insoluble precipitate with this test is silver chloride, and shows the presence of hydrochloric acid. Potassium hydroxide disengages ammonia; sulphuric acid, acetous vapors.

When evaporated to dryness, the residue is wholly dissipated by heat, with the odor of ammonia. It is incompatible with acids, the fixed alkalies and their carbonates, lime water, magnesia, magnesium sulphate, corrosive sublimate, the iron, copper, and zinc sulphates, and silver nitrate. When it contains free carbon dioxide it produces with lead acetate or subacetate a precipitate of lead carbonate, which, being mistaken for the sulphate, has led to the erroneous conclusion that sulphuric acid was present in the distilled vinegar, when this has been employed. *Ammonium acetate* is a salt of difficult crystallization, and very deliquescent. When perfect it probably has an alkaline reaction, like potassium and sodium acetates. It may be obtained by sublimation from a mixture of equal parts of dry potassium or calcium acetate and ammonium chloride, or, according to Berthelot, by dissolving glacial acetic acid in ammonia, keeping the retort cool, and adding enough water to prevent the crystallization of the salt during the neutralization; the solution is then evaporated in a current of dry, gaseous ammonia until the liquid solidifies on cooling. It is then introduced into a large dish, and this placed upon caustic lime, under a large bell glass, into which a considerable quantity of ammonia gas is injected. After a few days the crystalline mass is broken, and the dish replaced as before upon lime in an ammoniacal atmosphere, under the bell glass. When this operation has been repeated several times, a perfectly pure ammonium acetate is obtained, which crystallizes in large needles, like potassium nitrate, and resembles ammonium formate; it is extremely soluble in water, and does not possess an acid reaction. (*A. J. P.*, 1875, p. 25.) It is formed by the union of one molecule of acetic acid, $\text{H.C}_2\text{H}_3\text{O}_2$, with one group, NH_4 , from NH_4OH , the hydroxide, or $(\text{NH}_4)_2\text{CO}_3$, the carbonate. When evaporated to dryness, however, it readily yields an acid salt, $\text{C}_2\text{H}_3\text{O}_2.\text{NH}_4 + \text{C}_2\text{H}_3\text{O}_2.\text{H}$. The molecular weight of the normal salt is about 76.5.

Uses.—Solution of ammonium acetate is a feeble diaphoretic which was formerly much employed in febrile diseases.

Dose, from half a fluidounce to a fluidounce and a half (15 to 45 Cc.) every three or four hours, mixed with water and sweetened with sugar.

Off. Prep.—Liquor Ferri et Ammonii Acetatis, U. S.

LIQUOR AMMONII CITRATIS. Br.

SOLUTION OF AMMONIUM CITRATE

(l'iquor am-mō'nī-i cī-trā'tis)

Citrate d'Ammoniaque liquide, *Fr.*; Ammonium-citratlösung, Citronensaure Ammoniak-Flüssigkeit, *G.*

"Ammonium Carbonate, $1\frac{1}{2}$ ounces (Imperial) or 87.5 grammes or a sufficient quantity; Citric Acid, $2\frac{1}{2}$ ounces (Imp.) or 125 grammes; Distilled Water, a sufficient quantity. Dissolve the Citric Acid in five times its weight of Distilled Water; neutralize with Ammonium Carbonate; add sufficient Distilled Water to produce one pint (Imp. meas.) or one thousand cubic centimetres of the Solution. A little of the Solution, heated in a test-tube to expel carbonic anhydride, should be neutral or only slightly acid to test-papers. Solution of Ammonium Citrate should be preserved in a green glass bottle." *Br.*

This solution may be used for the same purposes as Solution of Ammonium Acetate.

Dose, from two to six fluidrachms (7.5 to 22.5 Cc.).

LIQUOR ANTISEPTICUS. U. S.

ANTISEPTIC SOLUTION

(l'iquor ān-tī-sēp'tī-cūs)

Liquor Antiseptique, *Fr.*; Antiseptische Lösung, *G.*

* "Boric Acid, twenty grammes [or 309 grains]; Benzoic Acid, one gramme [or 15 grains]; Thymol, one gramme [or 15 grains]; Eucalyptol, one-fourth cubic centimeter [or 4 minims]; Oil of Peppermint, one-half cubic centimeter [or 8 minims]; Oil of Gaultheria, one-fourth cubic centimeter [or 4 minims]; Oil of Thyme, one-tenth cubic centimeter [or 1.5 minims]; Alcohol, two hundred and fifty cubic centimeters [or 8 fluidounces, 218 minims]; Purified Talc, twenty grammes [or 309 grains]; Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Dissolve the Boric Acid in seven hundred cubic centimeters [or 23 fluidounces, 321 minims] of Water, and the Benzoic Acid in one hundred and fifty cubic centimeters [or 5 fluidounces, 35 minims] of Alcohol, and pour the aqueous solution into the alcoholic solution. Then dissolve, in a mortar, the Thymol in the Eucalyptol and Oils of Peppermint, Gaultheria, and Thyme; thoroughly incorporate the Purified Talc, and add, with constant trituration, the solution first prepared. Allow the mixture to stand, with occasional agitation, during forty-eight hours,

filter, add one hundred cubic centimeters [or 3 fluidounces, 183 minims] of Alcohol to the clear filtrate, and a sufficient quantity of Water to make the finished product measure one thousand cubic centimeters [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]." *U. S.*

This solution was introduced for the first time in the U. S. P. (8th Rev.) and is largely employed.

Uses.—This liquid is a feeble antiseptic solution of pleasant taste, especially adapted for use as a mouth wash; it is also used as an application to cuts and wounds to prevent festering and aid in healing them quickly.

LIQUOR ARSENI ET HYDRARGYRI IODIDI. U. S. (Br.)

SOLUTION OF ARSENOUS AND MERCURIC IODIDES. [Donovan's Solution]

(l'iquor ār-se-nī ēt hy-drār-gy-rī i-ōd'i-di)

"An aqueous solution, which should contain not less than 1 percent. of Arsenous Iodide and 1 percent. of Mercuric Iodide." *U. S.*

Liquor Arseni et Hydrargyri Iodidi, Br., Solution of Arsenous and Mercuric Iodides; Liquor Arsenici et Hydrargyri Iodidi, *Br.* 1867, *U. S.* 1870: Solution of Hydriodate of Arsenic and Mercury; Solutio Donovanii; Soluté d'Iodo-arsénite de Mercure, *Liquor* de Donovan, *Fr.*; Jodquecksilber Arseniklösung, *Donovansche Tropfen*, *G.*

* "Arsenous Iodide, ten grammes [or 154 grains]; Red Mercuric Iodide, ten grammes [or 154 grains]; Distilled Water, a sufficient quantity, to make one thousand grammes [or 35 ounces av., 120 grains]. Rub the Arsenous Iodide and Red Mercuric Iodide together in a mortar, add one hundred and fifty cubic centimeters [or 5 fluidounces, 35 minims] of Distilled Water, and continue the trituration until solution is effected. Filter the solution, and pass sufficient Distilled Water through the filter to make the product weigh one thousand grammes [or 35 ounces av., 120 grains]. Mix thoroughly." *U. S.*¹

"Arsenous Iodide, $87\frac{1}{2}$ grains (Imperial) or 10 grammes; Mercuric Iodide, $87\frac{1}{2}$ grains (Imp.) or 10 grammes; Distilled Water, a sufficient quantity. Triturate the Arsenous Iodide and Mercuric Iodide with three to four fluid ounces (Imp. meas.) or one hundred and

¹ *Clemens's Solution.*—Arsenic bromide was introduced as a remedy in diabetes by Clemens. It is best administered in the form of a solution, which has been prepared by R. F. Fairthorne according to the following formula: "77 grains of metallic arsenic in powder are added in small portions to 240 grains of bromine, the latter being placed in a long test-tube immersed in ice-water to control the otherwise violent reaction. One hundred grains of the tribromide obtained are dissolved in sufficient distilled water to make ten fluidounces. One minim will then contain one-forty-eighth of a grain." According to Clemens, the commencing dose of such a solution is one minim three times a day, increased gradually until the equivalent of one-fifth of a grain of the salt is daily exhibited. The clinical reports in regard to this remedy in diabetes seem to indicate that along with a restricted diet it is occasionally of distinct service, but in the majority of instances fails to accomplish good.

fifty to two hundred cubic centimetres of the Distilled Water until nearly all is dissolved; pass through a filter; wash the latter with sufficient Distilled Water to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Solution. A clear pale yellow liquid with a metallic taste. It affords the reactions characteristic of mercuric salts, arsenium, and iodides. 110 minims correspond to 1 grain of Arsenious Iodide, AsI_3 , and to 1 grain of Mercuric Iodide, HgI_2 ; 100 cubic centimetres correspond to 1 gramme of each salt." *Br.*

This solution was introduced to the notice of the medical profession in 1839 by Donovan of Dublin, as a therapeutic agent combining the medicinal virtues of its three ingredients, and was adopted as an official preparation in the U. S. and Dublin Pharmacopœias of 1850. It was dropped from the British Pharmacopœia of 1867, but reintroduced in the 1885 revision, and fortunately made to correspond in strength with the U. S. preparation,—namely, 1 per cent. of each of the active ingredients. The formula of the U. S. Pharmacopœia is the simplified one of Procter, which consists essentially in dissolving equal weights of arsenic triiodide and mercuric iodide (red iodide) in a measured quantity of distilled water.

Properties.—"A clear, colorless or pale yellowish liquid, without odor, and having a disagreeable metallic taste." *U. S.* Sometimes, however, the color is orange-yellow, owing to the presence of free iodine. This may be recombined by rubbing the solution with a little metallic mercury, or arsenic in fine powder, and the proper hue be thus restored. The solution is incompatible with laudanum and the soluble salts of morphine. The British solution has the sp. gr. 1.016.

Uses.—This preparation has been found decidedly useful as an alterative in various diseases of the skin, such as the different forms of *psoriasis*, *impetigo*, *porrigo*, *lepra*, *pityriasis*, *lupus*, and *venereal eruptions*, both papular and scaly. In *chronic rheumatism* and in advanced specific diseases, especially "*night pains*," it is often useful.

Dose, from one to five minims (0.06 to 0.3 Cc.), three times a day, given preferably in distilled water.

LIQUOR ATROPINÆ SULPHATIS. *Br.*

SOLUTION OF ATROPINE SULPHATE

(*l'iquor āt-rō-pī'næ sŭl-phā'tis*)

Soluté de Sulfate d'Atropine, *Fr.*; Schwefelsaure Atropinlösung, *G.*

"Atropine Sulphate, $17\frac{1}{2}$ grains (Imperial) or 1 gramme; Salicylic Acid, 2 grains (Imp.) or 0.12 gramme; Distilled Water, 4 fl. ounces (Imp. meas.) or 100 cubic centimetres or a sufficient quantity. Dissolve the Atropine Sulphate and Salicylic Acid in sufficient recently boiled and cooled Distilled Water to produce *four fluid ounces* (Imp. meas.) or one hundred

cubic centimetres of the solution. 110 minims contain 1 grain of Atropine Sulphate; 100 cubic centimetres contain 1 gramme." *Br.*

This solution contains 1 per cent. of atropine sulphate. Camphor water was substituted for distilled water on account of its antiseptic properties at the 1885 revision. Salicylic acid and distilled water are now used (1898) with the same object in view.

Dose, one minim (0.06 Cc.).

LIQUOR BISMUTHI ET AMMONII CITRATIS. *Br.*

SOLUTION OF BISMUTH AND AMMONIUM CITRATE

(*l'iquor bis-mŭ'thī ēt ām-mō'nī-i ej-trā'tis*)

Liquor Bismuthi; Solution of Bismuth, Liquid Bismuth; Soluté de Citrate de Bismuth ammoniacal, *Fr.*; Citronensaure Wisnuth-Ammoniak-Lösung, Wisnuth-Ammoniakcitratlösung, *G.*

"Bismuth Oxynitrate, 613 grains (Imperial) or 70 grammes; Potassium Citrate, 613 grains (Imp.) or 70 grammes; Potassium Carbonate, 175 grains (Imp.) or 20 grammes; Nitric Acid, 1 fl. ounce (Imp. meas.) or 50 cubic centimetres; Solution of Ammonia, Distilled Water, of each a sufficient quantity. Dissolve the Bismuth Oxynitrate in the Nitric Acid diluted with an equal volume of Distilled Water; add Distilled Water with constant stirring, until the liquid is very faintly opalescent; add the Potassium Citrate and Carbonate dissolved in a little Distilled Water; heat the liquid to the boiling point; cool; separate the precipitate; wash it with Distilled Water until free from nitrates. Gradually add Solution of Ammonia to the moist precipitate until it is just dissolved; dilute with Distilled Water to *one pint* (Imp. meas.) or one thousand cubic centimetres; filter." *Br.*

The British Pharmacopœia (1898) adopted a new process for this preparation, which is a modification of Bartlett's process. (See below.) An acid solution of bismuth is treated with a solution of potassium citrate and potassium carbonate, the precipitate washed and dissolved in solution of ammonia, and then diluted with water in proper proportions. (See *Bismuthi et Ammonii Citras*, p. 238.) For suggested improvements in manipulating this process see a paper by Cowley and Catford in *P. J.*, 1899, 604; also *Y. B. P.*, 1899, 451.

Some years since, a secret preparation was made and sold by Schacht of Clifton, England, under the name of *Liquor Bismuthi*. Ch. R. C. Tichborne, having analyzed the liquid and found it to contain bismuth oxide, ammonia, and citric acid, announced the discovery at a meeting of the Pharmaceutical Society, when Schacht, being present, acknowledged the correctness of the analysis, stating, at the same time, that he had never made a secret of the composition of his solution to medical practitioners, and that a fluidrachm of his liquid contained one grain of the trioxide. (*P. J.*,

1864, p. 301.) A formula for the preparation was given by Tichborne, which, however, on repeated trial by N. Gray Bartlett of Chicago, proved to be impracticable. After numerous experiments, Bartlett succeeded in making a solution which had all the desired qualities. (See *A. J. P.*, Jan. 1865.) He first prepares a bismuth citrate by dissolving a troyounce of bismuth subcarbonate in 720 grains of nitric acid, diluting the solution after effervescence has ceased with a fluidounce and a half of distilled water gradually introduced, and then adding this solution, slowly and with constant stirring, to another solution made by dissolving 600 grains of potassium citrate in *two pints* of distilled water. By an interchange, potassium nitrate and bismuth citrate are formed, the latter of which, being insoluble, is precipitated, and is obtained by throwing the whole upon a filter, thoroughly washing the salt with distilled water, and then drying it on bibulous paper with a gentle heat. The next step is to prepare the bismuth and ammonium citrate. This is done by rubbing the bismuth citrate with sufficient distilled water to make a paste, and adding to this gradually, and with constant trituration, stronger ammonia water until the citrate is dissolved, care being taken to avoid an excess of ammonia. The solution is now filtered, and spread on glass to dry.

Various modifications of Bartlett's process have been suggested, though it may be doubted whether any one of them, on the whole, is preferable to the original. Besides the processes offered by T. P. Blunt and Tichborne, in England, A. E. Ebert and Markoe have each proposed a modification of Bartlett's process. (See *A. J. P.*, 1866, p. 1, and 1869, p. 151.) In Ebert's formula the solution of bismuth nitrate is decomposed by potassium hydroxide in the presence of citric acid, instead of the potassium citrate already formed; in Markoe's, crystallized sodium carbonate is substituted for the caustic alkali, to which various objections exist. After precipitating the solution of bismuth nitrate to which citric acid has been added, with sodium carbonate, washing the precipitate to get rid of the sodium nitrate, and dissolving the residue of the precipitate in ammonia water, Markoe completes the process by determining the proportion of bismuth trioxide contained in the solution, and then diluting the liquid so that each fluidrachm shall contain one grain of trioxide. For other methods of making this solution, see 17th ed. *U. S. D.*, 794.

The British Pharmacopœia describes this preparation as "a colorless solution, with a slightly metallic taste. Specific gravity 1.070. Slightly alkaline to *test-paper*; is freely miscible with *water*; heated with *alkalies* evolves ammonia, and yields a white precipitate. Evaporated to dryness and the product ignited, a residue with a yellow edge results, which when suitably treated should not yield any reaction characteristic of silver, lead, copper, arse-

nium, iron, selenium, or tellurium. A mixture of 10 cubic centimetres of the Solution with 40 cubic centimetres of *water*, treated with *hydrogen sulphide* in excess, yields a black precipitate, which, when washed and dried, should weigh at least 0.55 gramme. 1 fluid drachm contains an amount of bismuth equivalent to about 3 grains, or 1 cubic centimetre the equivalent of 0.5 gramme, of Bismuth Oxide." *Br.*

Bismuth and ammonium citrate, obtained by Bartlett's process, is in fine, glossy, translucent, colorless scales, of a slightly acidulous, somewhat metallic, not disagreeable taste, very soluble in water, but not deliquescent, and of an acid reaction. (See page 238.) From an analysis by Bartlett, it appears to possess the formula $\text{Bi}_2\text{C}_6\text{H}_5\text{O}_7\cdot\text{NH}_3 + 3\text{H}_2\text{O}$. Rother, however (1876), considers that the formula should be written $\text{C}_6\text{H}_5\text{O}_7(\text{NH}_4)_3\text{Bi}(\text{OH})_3$.

There is no occasion for a permanent solution of this salt, as it may at any time be dissolved when wanted for use. But, as it is in the liquid form that it has obtained its present reputation, we give a formula for a permanent solution prepared by Bartlett. Dissolve 260 grains of bismuth and ammonium citrate in fourteen fluidounces of distilled water, neutralize the solution with ammonia water, and add two fluidounces of alcohol. The solution of the salt without addition is liable to spontaneous decomposition, but, in the opinion of Bartlett, it is completely protected by the ammonia and alcohol, so that in this state it will keep indefinitely.

Uses.—This preparation is much more astringent than are the insoluble salts of bismuth, and is at the same time irritant, and not possessed of the peculiar medicinal properties which grow out of insolubility of the subnitrate or subcarbonate. It is, therefore, not a substitute for these, and is adapted to the treatment of *diarrhœas* of relaxation rather than of irritation.

Dose, from one-half to one fluidrachm (1.8 to 3.75 Cc.).

LIQUOR CALCIS. U. S., Br.

LIME WATER SOLUTION OF CALCIUM HYDROXIDE

(*Liquor cal'cis*)

"A saturated aqueous solution, which should contain not less than 0.14 percent. of pure Calcium Hydroxide [$\text{Ca}(\text{OH})_2 = 73.56$]. The percentage of Calcium Hydroxide varies with the temperature at which the saturated solution is prepared, being about 0.17 percent. at 15° C. (59° F.), the percentage diminishing as the temperature rises." *U. S.*

Aqua Calcarie Ustæ, Calcaria Soluta, Aqua Calcis; Solution of Calcium Hydrate, Solution of Lime; Eau (Soluté) de Chaux, *Fr. Cod.*; Aqua Calcarie, *P. G.*; Kalkwasser, *G.*; Acqua di calce, *It.*; Agua de cal, *Sp.*

* "Lime, *twelve grammes* [or 185 grains]; Distilled Water, a sufficient quantity. Slake

the Lime by the very gradual addition of *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Distilled Water, and agitate occasionally during half an hour. Allow the suspended particles to subside, decant the supernatant liquid and reject it. Then add to the residue *thirty-six hundred cubic centimeters* [or 121 fluidounces, 350 minims] of Distilled Water, agitate thoroughly, let the mixture stand for twenty-four hours, agitate again, then let the coarser particles of solid matter subside, and pour the liquid, holding the undissolved calcium hydroxide in suspension, into a glass-stoppered bottle. From time to time shake the bottle, so as to keep the solution saturated. Pour off the clear liquid when required for use." *U. S.*

"Calcium Hydroxide, 2 ounces (Imperial) or 50 grammes; Distilled Water, a sufficient quantity. Wash the Calcium Hydroxide with Distilled Water until free from chlorides; then shake it with *one gallon* (Imp. meas.) or four litres of Distilled Water in a stoppered green glass bottle for two or three minutes; set aside for twelve hours. The clear Solution may be drawn off with a siphon as it is required for use, and should then be transferred to a green glass bottle." *Br.*

A solution of calcium hydroxide, $\text{Ca}(\text{OH})_2$, in water is the result of these processes. By the slaking of the lime it is reduced to powder, and rendered more easily diffusible through the water. According to both Pharmacopœias, the solution is to be kept in bottles with a portion of undissolved hydroxide, which causes it always to be saturated whatever may be the temperature and to whatever extent it may be exposed to the air. If care be taken to have a considerable quantity of the solution in the bottle, and to avoid unnecessary agitation, the upper portion will always remain sufficiently clear for use. The employment of distilled water as the solvent may seem a useless refinement, but in many places the common water is very impure. Water dissolves but a minute proportion of lime, and, contrary to the general law, less when hot than when cold. Hence the propriety of employing cold water in the process. According to Phillips, a pint of water (the wine pint of the U. S. P. 1870) at 212°F . dissolves 5.6 grains of lime, at 60°F . 9.7 grains. For Green's automatic device for dispensing lime water in excellent condition, see *Proc. A. Ph. A.*, 1893, 474; see also 1904, 66.

The practice of using the undissolved lime indefinitely by refilling the bottle with water, is reprehensible, as notwithstanding the excess, its tendency to become carbonated and insoluble is great, and lime water is often dispensed deficient in strength; it is much safer to use the lime but once or twice than to run the risk of dispensing a liquid of insufficient strength.

Properties.—Lime water is "a clear, colorless liquid without odor, and having an alkaline taste. It absorbs carbon dioxide from the air,

a pellicle of calcium carbonate forming on the surface of the liquid. On being heated it becomes turbid, due to the separation of calcium hydroxide which redissolves when the liquid is cooled. It gives a strongly alkaline reaction with red litmus paper. The alkaline reaction of the Solution should entirely disappear, after it has been saturated with carbon dioxide, and subsequently boiled (absence of *alkalies* and their *carbonates*). In other respects it should conform to the reactions and tests for an aqueous solution of lime given under *Calx*. Fifty Cc. should require, for complete neutralization, not less than 19 Cc. of tenth-normal sulphuric acid V.S. (corresponding to about 0.14 percent. of calcium hydroxide), phenolphthalein T.S. being used as indicator." *U. S.* Exposed to the air it attracts carbon dioxide, and becomes covered with a pellicle of insoluble calcium carbonate, which, subsiding after a time, is replaced by another, and so on successively until the whole of the lime is exhausted. Hence the necessity of keeping lime water either in closely corked bottles which should be full, or, what is more convenient, in bottles with an excess of lime. "24 cubic centimetres should require for neutralization 10 cubic centimetres of the *decinormal volumetric solution of sulphuric acid*. It should yield no characteristic reaction with the tests for lead or for chlorides. 1 fluid ounce contains the equivalent of about $\frac{1}{2}$ grain, or 1000 cubic centimetres rather more than 1 gramme, of Lime, CaO ." *Br.*

Uses.—Lime water is antacid, tonic, and astringent, often very useful in *dyspepsia* with acidity of stomach, *diarrhœa* and *diabetes*. Mixed with from one to three measures of milk, which completely covers its offensive taste, it is one of the best remedies in our possession for *nausea* and *vomiting* dependent on irritability of stomach. In severe repeated vomiting with loss of digestive power a diet exclusively of lime water and milk (one to six) is often very effectual. Having been found to possess the property of dissolving false membrane, it has naturally been employed as a local remedy in *pseudo-membranous croup*. There are two methods of applying the remedy; one by directing lime water spray, produced by the atomizer, so that it shall be inhaled by the patient; the other by causing the patient to inhale freely the vapors arising from lime undergoing the process of slaking with water. When employed to allay *nausea*, it is usually given in the dose of a tablespoonful mixed with the same quantity of milk, and repeated at intervals of half an hour, an hour, or two hours. If too long continued it debilitates the stomach. The urine of persons who take large quantities of lime water is often alkaline, and sometimes distinctly ammoniacal. According to the researches of John J. Abel, this is due to the presence in the urine of calcium carbamate, which is prone to undergo ammoniacal disintegration.

Dose, one to four fluidounces (30 to 120 Cc.).

LIQUOR CALCIS CHLORINATÆ. Br.

SOLUTION OF CHLORINATED LIME

(lī'quor cāl'cīs chlō-rī-nā'tæ)

Soluté d'Hypochlorite de Chaux, *Fr. Cod.*; Chlorure de Chaux liquide, *Fr.*; Chlorkalklösung, Chlorkalk-Flüssigkeit, *G.*

"Chlorinated Lime, 1 pound (Imperial) or 500 grammes; Distilled Water, 1 gallon (Imp. meas.) or 5 litres. Mix; transfer the mixture to a stoppered bottle; set aside for three hours, shaking occasionally; filter through calico. Preserve the filtrate in a stoppered bottle in a cool, dark place." *Br.*

For the properties and uses of this preparation, see *Calc Chlorinata*. The British Pharmacopœia gives the following test of its strength: "Specific gravity about 1.055. Each gramme mixed with 0.5 gramme of potassium iodide dissolved in water, when acidulated with 1 cubic centimetre of hydrochloric acid, gives a brownish-red solution which requires for the discharge of its color not less than 5.6 cubic centimetres of the volumetric solution of sodium thiosulphate, corresponding to 2 per cent. of available chlorine. The Solution should yield, when fresh, about 3 per cent. of available chlorine." *Br.* This determines its strength in chlorine, by ascertaining the quantity of iodine which the chlorine contained in it is capable of separating from potassium iodide. Notwithstanding, however, that a test of its character is thus given by the Pharmacopœia, its strength must vary according to the quality of the chlorinated lime employed. It is one of the best antidotes for hydrogen sulphide, ammonium sulphhydrate, potassium sulphide, and hydrocyanic acid. For external application the solution may be diluted with twice its bulk of water, or may be used of the full strength in some cutaneous affections.

Dose, for internal use, from twenty minims to a fluidrachm (1.3 to 3.75 Cc.).

LIQUOR CALUMBÆ CONCENTRATUS.

Br.

CONCENTRATED SOLUTION OF CALUMBA

(lī'quor cā-lūm'bæ cōn-cēn-trā'tūs)

"Calumba Root, in No. 5 powder, 10 ounces (Imperial) or 500 grammes; Alcohol (90 per cent.), 4½ fl. ounces (Imp. meas.) or 225 cubic centimetres; Distilled Water, 20 fl. ounces (Imp. meas.) or 1000 cubic centimetres or a sufficient quantity. Macerate the Calumba for twenty-four hours with ten fluid ounces (Imp. meas.) or five hundred cubic centimetres of Distilled Water, press strongly; again macerate

the residue for twenty-four hours with ten fluid ounces (Imp. meas.) or five hundred cubic centimetres of Distilled Water; press strongly. Mix the expressed liquids, and heat for five minutes at 180° F. (82.2° C.). When cold add the Alcohol; set aside; decant or filter, adding sufficient Distilled Water to produce one pint (Imp. meas.) or one thousand cubic centimetres of the Concentrated Solution." *Br.*

This was a new preparation of the last British Pharmacopœia. It should, in our opinion, be named "*Infusum Calumbæ Concentratum*," as it is nothing more than a concentrated infusion preserved with alcohol, and intended to be used by the pharmacist for the quick preparation of the infusion of calumba by dilution with water. It is ten times as strong as the ordinary infusion.

Dose, from one-half to one fluidrachm (1.8 to 3.75 Cc.).

LIQUOR CAOUTCHOUC. Br.

SOLUTION OF INDIA-RUBBER

(lī'quor caōt'chōuc)

"India-rubber, 1 ounce (Imperial) or 50 grammes; Benzol, 10 fl. ounces (Imp. meas.) or 500 cubic centimetres; Carbon Bisulphide, 10 fl. ounces (Imp. meas.) or 500 cubic centimetres. Cut the India-rubber into fine shreds, and place it in a well-stoppered bottle containing the previously mixed Benzol and Carbon Bisulphide. Set aside in a cool place, and agitate occasionally until solution is effected." *Br.*

This solution is an improvement on the solution of gutta-percha formerly official; it was introduced into the *Br. Pharm.* (1898) mainly for use in the preparation of mustard paper. It may be used like collodion as an external protective application.

Off. Prep.—Charta Sinapis, *Br.*

LIQUOR CHIRATÆ CONCENTRATUS.

Br.

CONCENTRATED SOLUTION OF CHIRETTA

(lī'quor ghi-rā'tæ cōn-cēn-trā'tūs)

"Chiretta, in No. 40 powder, 10 ounces (Imperial) or 500 grammes; Alcohol (20 per cent.), 25 fl. ounces (Imp. meas.) or 1250 cubic centimetres or a sufficient quantity. Moisten the Chiretta with five fluid ounces (Imp. meas.) or two hundred and fifty cubic centimetres of the Alcohol; pack in a closed percolator; set aside for three days; percolate with the remaining Alcohol, added in ten equal portions at intervals of twelve hours; continue percolation with more Alcohol until the product measures one pint (Imp. meas.) or one thousand cubic centimetres." *Br.*

This is a "concentrated" infusion of the Br. Ph. 1898, intended to be used by the pharmacist for making the ordinary infusion of chiretta by dilution with water. It is twenty times as strong as the infusion of chiretta, Br. Ph. 1885.

Dose, from one-half to one fluidrachm (1.8 to 3.75 Cc.).

LIQUOR CHLORI COMPOSITUS. U. S.

COMPOUND SOLUTION OF CHLORINE, CHLORINE WATER [To replace Aqua Chlori, Pharm. 1890]

(لیقور څلورې ډېر ځم-پوښ-تېس)

"An aqueous solution, containing, when freshly prepared, about 0.4 percent. of Chlorine [$\text{Cl} = 35.18$], with some oxides of chlorine and potassium chloride." U. S. "Produced by saturating Distilled Water with chlorine. The chlorine may be obtained by the interaction of Hydrochloric Acid and Manganese Peroxide, and should be purified by passing through a small quantity of water contained in a wash-bottle." Br. Appendix.

Solution of Chlorine, Br.: Aqua Chlorini, U. S. P. 1870: Aqua Chlori, Chlorum Solutum, Aqua Oxymuriatica; Soluté de Chlore composé, Eau Chlorée, Chlore liquide, Fr.: Aqua Chlorata, P. G.; Zusammen-gesetzte Chlörösung, Chlorwasser, G.; Acqua di cloro, It.; Agua de cloro, Sp.

* "Potassium Chlorate, granulated, five grammes [or 77 grains]; Hydrochloric Acid, eighteen cubic centimeters [or 292 minims]; Distilled Water, a sufficient quantity, to make about one thousand cubic centimeters [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Add the Hydrochloric Acid, diluted with twenty cubic centimeters [or 325 minims] of Distilled Water, to the Potassium Chlorate contained in a flask of the capacity of about two thousand cubic centimeters [or 67 fluidounces, 301 minims]. Insert in the flask a stopper perforated to admit a funnel of the capacity of about one hundred cubic centimeters [or 3 fluidounces, 183 minims] containing about ten grammes [or 154 grains] of purified cotton well wetted with cold water; place the flask on a water-bath containing boiling water, for a period of from two to three minutes; when the flask is completely filled with a greenish-yellow gas, remove it from the bath and add cold Distilled Water through the cotton in the funnel, in two separate portions of five hundred cubic centimeters [or 16 fluidounces, 435 minims] each. After the addition of each separate portion of cold Distilled Water, stopper the flask securely, invert, and thoroughly agitate the contents. This solution should be freshly made when wanted." U. S.

In the U. S. P. (8th Rev.) the old process for making chlorine water was dismissed and the present process introduced under the name of *Liquor Chlori Compositus*. This contains besides chlorine some chlorine dioxide and a

little potassium chloride, and it has been classed with the "Liquors." The reaction is as follows:

The process of the U. S. P. 1890 is appended.¹ Compound solution of chlorine can be used when chlorine water is directed or prescribed in all cases, except in some delicate chemical tests; its advantages lie chiefly in the greater ease and simplicity of the process.

Properties.—Chlorine water of the U. S. P. 1890 was described as "a clear, greenish-yellow liquid, having the suffocating odor and disagreeable taste of Chlorine, and leaving no residue on evaporation. It instantly decolorizes dilute solution of litmus, indigo, and other vegetable coloring matters. When shaken with an excess of mercury until the odor of Chlorine has disappeared, the remaining liquid should be at most but faintly acid (limit of hydrochloric acid). On adding 17.7 Gm. of Chlorine Water

¹ *Aqua Chlori, Chlorine water, U. S. 1890.*—"Manganese Dioxide, ten grammes [or 154 grains]; Hydrochloric Acid, thirty-five cubic centimeters [or 1 fluidounce, 88 minims]; Water, seventy-five cubic centimeters [or 2½ fluidounces]; Distilled Water, four hundred cubic centimeters [or 13½ fluidounces]. Place the Dioxide in a flask connected by a suitable tube with a small wash-bottle containing fifty cubic centimeters [or 1½ fluidounces] of Water, and connect this with a bottle having a capacity of one thousand cubic centimeters [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms], and containing four hundred cubic centimeters [or 13½ fluidounces] of Distilled Water which has previously been boiled and allowed to cool. Add to the Dioxide in the generating flask the Hydrochloric Acid, previously diluted with twenty-five cubic centimeters [or 1 fluidounce] of Water, and, by means of a sand-bath, apply a gentle heat. Conduct the generated Chlorine through the Water contained in the wash-bottle into the bottle containing the Distilled Water, which should be loosely stoppered with cotton and kept, during the operation, at a temperature of about 10° C. (50° F.). When the air has been entirely displaced by the gas, disconnect the bottle from the apparatus, and, having inserted the stopper, shake the bottle, loosening the stopper from time to time, until the gas ceases to be absorbed. If necessary, reconnect the bottle with the apparatus, and continue passing the gas and agitating, until the Distilled Water is saturated. Finally, pour the Chlorine Water into small, dark amber-colored, glass-stoppered bottles, which should be completely filled therewith, and keep them in a dark and cool place. Chlorine Water, even when kept from light and air, is apt to deteriorate. When it is required of full strength, it should be freshly prepared." U. S. 1890.

The chlorine gas is extricated from the hydrochloric acid by the manganese dioxide, while the manganous chloride and water produced remain in the flask, and the chlorine is passed, through an intermediate vessel containing a little water for purifying it, into the bottle containing the distilled water, loosely stoppered, until the vacant part of the bottle is filled with it to the exclusion of the atmospheric air.

The bottle, being then corked, is shaken so as to cause the absorption of the gas by the water. Of course the stopper must be from time to time loosened, in order to allow the entrance of air to supply the partial vacuum created by the absorption of the chlorine. The chlorine water is directed to be kept secluded from the light, because otherwise it would be converted into hydrochloric acid, through the union of the chlorine with the hydrogen of the water.

Deacon's process.—Henry Deacon has discovered that chlorine may be made by passing hydrochloric acid vapor and oxygen over copper sulphate at a temperature of from 400° to 700° F., the copper salt coming out unchanged. For details of this process the reader is referred to *Roscoe and Schorlemmer's Chemistry*, vol. i. p. 114.

to a solution of 1 Gm. of potassium iodide in 10 Cc. of water, the resulting deep-red liquid should require for complete decoloration not less than 20 Cc. of sodium hyposulphite decinormal volumetric solution (corresponding to at least 0.4 per cent. of Chlorine)." *U. S.* 1890. Like gaseous chlorine, it destroys vegetable colors. When cooled to about the freezing point, it forms deep yellow crystalline plates, consisting of chlorine hydrate. It is intended to contain at least twice its volume of the gas. According to Riegel and Walz, chlorine water containing two and a half volumes of the gas at 12.2° C. (54° F.) keeps best. The official test indicates the quantity of chlorine in the solution, by the amount of the hyposulphite required to decolorize an equivalent quantity of iodine, liberated from the potassium iodide. Chlorine water decomposes on keeping, and both Pharmacopœias direct that "it should be recently prepared." In view of the unstable properties of chlorine water, liquid chlorine in sealed glass tubes (each containing five grammes) can be procured in commerce, the contents of one tube being sufficient to prepare a litre of the water.

Chlorine is an elementary gaseous fluid of a greenish-yellow color and characteristic odor and taste. It is a supporter of combustion. Its specific gravity is 2.47, and its atomic weight 35.18. When the attempt is made to breathe it, even much diluted, it excites cough and a sense of suffocation, and causes a discharge from the mucous membrane of the nostrils and bronchial tubes. Breathed in considerable quantities, it produces spitting of blood, violent pains, and sometimes death.

Uses.—Chlorine water has been employed internally in *typhus*, *scarlatina*, *malignant sore throat*, and *diphtheria*, but has fallen into complete desuetude. Externally it is employed, duly diluted, as a gargle in *small-pox*, *scarlatina*, and *putrid sore throat*, as a wash for ill-conditioned *ulcers* and *cancerous sores*, and as a local bath in *diseases of the liver*. It has been used with advantage as an application to *buboes* and large *abscesses*. As it depends upon chlorine for its activity, its medicinal properties coincide with those of chlorinated lime and chlorinated soda, under which heads they are more particularly given. It should not be prescribed in mixtures, almost all organic substances causing a rapid disappearance of the chlorine. Even sugar has this action, and glycerin still more markedly.

Gaseous chlorine has been employed in *chronic bronchitis* and *pulmonary consumption*, exhibited by inhalation, in minute quantities, four or six times a day. It has been asserted that its first effect is to produce some dryness of the fauces, with increased expectoration for a time, followed ultimately by diminution of the sputa and by amendment. The liquid in the inhaler may be formed either of water containing from ten to thirty minims (0.6 to 1.8 Cc.) of chlorine water, or of chlorinated

lime dissolved in forty parts of water, to which a drop or two of sulphuric acid must be added, each time the inhalation is practised. The inhaler should be placed in water heated to about 37.7° C. (100° F.).

Dose, of chlorine water, one to four fluidrachms (3.75 to 15 Cc.).

LIQUOR CRESOLIS COMPOSITUS. U. S.

COMPOUND SOLUTION OF CRESOL

(l'iquor cre-sô'lis com-pôz'î-tûs)

Soluté de Crésol composé, *Fr.*; Liquor Cresoli saponatus, *P. G.*; Kresolseifenlösung, *G.*

* "Cresol, five hundred grammes [or 17 ounces av., 279 grains]; Linseed Oil, three hundred and fifty grammes [or 12 ounces av., 151 grains]; Potassium Hydroxide, eighty grammes [or 2 ounces av., 360 grains]; Water, a sufficient quantity, to make one thousand grammes [or 35 ounces av., 120 grains]. Dissolve the Potassium Hydroxide in fifty grammes [or 1 ounce av., 334 grains] of Water in a tared dish, add the Linseed Oil, and mix thoroughly. Then add the Cresol and stir, until a clear solution is produced, and finally sufficient Water to make the finished product weigh one thousand grammes [or 35 ounces av., 120 grains]." *U. S.*

Compound Solution of Cresol was introduced into the *U. S. P.* (8th Rev.) to supply the demand for an antiseptic solution which mixes freely with water. With some samples of cresol there has been experienced some difficulty in securing immediately a clear solution, showing that combination has not been effected, but by allowing the mixture to stand, with occasional stirring, the solution will become clear. LaWall and Cook (*A. J. P.*, 1906, 169) suggest a modification of the manipulation which secures a clear solution immediately; it is as follows: "Heat the linseed oil (350 grammes) in a deep capacious vessel, on a water bath, to a temperature of about 70° C. Dissolve the potassium hydroxide (80 grammes) in 450 Cc. of water, warm the solution to about 70° C., add it to the linseed oil and mix thoroughly. Then incorporate 40 Cc. of alcohol and continue the heat without stirring until a small portion of the mixture is found to be soluble in boiling water without the separation of oily drops. The soap, thus prepared, is now dissolved in 500 grammes of cresol and a sufficient quantity of water added to make the solution weigh 1000 grammes."

Uses.—This solution is intended as a substitute for the many commercial preparations of cresol on the market. Although it forms a clear solution with distilled water, with tap water it becomes cloudy, owing to precipitation of lime soaps. This change, however, does not appear to interfere with its therapeutic properties. It is a powerful germicidal mixture, surpassing phenol as a destroyer of micro-organisms. It is also less caustic than

phenol, but the statement that it is much less poisonous has been shown to be untrue. It is especially useful for sterilizing instruments and the skin, its soapy nature making it peculiarly valuable for the latter purpose. It may be diluted with from 30 to 90 times its bulk of water (3 per cent. to 1 per cent. solution). It has been used to a small extent internally as an antiseptic in fermentative gastritis.

Dose, one to two minims (0.06 to 0.12 Ce.).

LIQUOR CUSPARIÆ CONCENTRATUS. Br.

CONCENTRATED SOLUTION OF CUSPARIA

(lī'quor cūs-pā'rī-æ cōn-cēn-trā'tūs)

"Cusparia Bark, in No. 40 powder, 10 ounces (Imperial) or 500 grammes; Alcohol (20 per cent.), 25 fl. ounces (Imp. meas.) or 1250 cubic centimetres or a sufficient quantity. Moisten the Cusparia with five fluid ounces (Imp. meas.) or two hundred and fifty cubic centimetres of the Alcohol; pack in a closed percolator; set aside for three days; percolate with the remaining Alcohol, added in ten equal portions at intervals of twelve hours; continue percolation with more Alcohol until the product measures one pint (Imp. meas.) or one thousand cubic centimetres." *Br.*

This is a concentrated infusion of the *Br. Pharm.* 1898, intended to be used by the pharmacist for making infusion of cusparia by dilution with water. It is ten times as strong as the infusion of cusparia (*Br. Pharm.* 1885).

Dose, from one-half to one fluidrachm (1.8 to 3.75 Ce.).

LIQUOR EPISPASTICUS. Br.

BLISTERING LIQUID

(lī'quor ēp-l-spās'tī-cūs)

Liniamentum Cantharidis; *Liqueur Vésicant*. *Hulle de Cantharides térébenthinée*, *Fr.*; *Spanischfliegenliniment*, *Blasenziehende Flüssigkeit*, *G.*

"Cantharides, in No. 20 powder, 10 ounces (Imperial) or 500 grammes; Acetic Ether, a sufficient quantity. Mix the Cantharides with five fluid ounces (Imp. meas.) or two hundred and fifty cubic centimetres of Acetic Ether; pack in a percolator; at the expiration of twenty-four hours pour Acetic Ether over the contents of the percolator; allow the solution to pass slowly through until one pint (Imp. meas.) or one thousand cubic centimetres of the Liquid is obtained. This preparation is twice the strength of the Blistering Liquid of the *British Pharmacopœia* of 1885." *Br.* This liquid is used in making the *British Blistering Collodion*. (See p. 386.)¹ Greenish and

Wilson propose that the official blistering liquid be prepared by the following formula: Cantharidin, 1 part; castor oil, 6 parts; rosin 3 parts; acetic ether, enough to make 300 fluid parts. The castor oil and rosin are added to replace the natural fat of the cantharides, and are necessary to aid the absorption of the cantharides by the skin. (*P. J.*, 1898, 259.)

Off. Prep.—*Collodium Vesicans*, *Br.*

LIQUOR ETHYL NITRITIS. Br.

SOLUTION OF ETHYL NITRITE

(lī'quor ē'thŷl nī-trī'tīs)

"A mixture of ninety-five parts by volume of Absolute Alcohol with five parts by volume of Glycerin, containing when freshly made 3 per cent. by weight, and even when long kept not less than 2½ per cent. by weight of ethyl nitrite. The ethyl nitrite is obtained by the interaction of alcohol (90 per cent.), sodium nitrite, and diluted sulphuric acid, at a low temperature." *Br.*

Soluté de Nitrite d'Ethyle, *Fr.*; *Aethylnitritlösung*, *G.*

This was a new official preparation in the *Br. Ph.* 1898; it might be called improved spirit of nitrous ether; it is difficult to explain the reason for its introduction without the dismissal of spirit of nitrous ether; the strength is very slightly greater than that of the spirit, and a choice should be made between them. The addition of glycerin as a preservative, and the substitution of absolute alcohol for rectified spirit, are relied upon to make a permanent solution. This method was proposed by Dunstan and Dymond (*P. J.*, 1888, 861), who believe that ethyl nitrite is the sole valuable constituent in spirit of nitrous ether; glycerin prevents loss of the very volatile ethyl nitrite, while the absence of water is secured by the use of absolute alcohol, water in the alcohol being shown to be the principal cause of decomposition and loss of ethyl nitrite. Solution of ethyl nitrite was strongly recommended by Leech, and the advantage claimed for it is that it is free from aldehyde. The increased cost, due to the use of absolute alcohol, will be apt to prevent the extensive use of the Solution. It is described as "a limpid liquid, practically colorless, of characteristic apple-like odor and taste. It is highly inflammable. Specific gravity 0.823 to 0.826. When Solution of Ethyl Nitrite is poured on an acidulated strong solution of ferrous sulphate contained in a test-tube, a deep olive-brown coloration is produced at the surface of contact of the two

¹ Very nearly corresponding to this preparation is the *Liniamentum Cantharidis*, or *Cantharides Liniement*, of the U. S. P. 1880. Made according to the formula, it is a very active counter-irritant, when too freely applied producing deep vesication. "Can-

tharides, in No. 60 powder, fifteen parts [or one ounce av.]; Oil of Turpentine, a sufficient quantity, to make one hundred parts [or half a pint]. Digest the Cantharides with one hundred parts [or half a pint] of Oil of Turpentine in a closed vessel, by means of a water-bath, for three hours; then strain and add enough Oil of Turpentine through the strainer to make the Liniement weigh one hundred parts [or measure half a pint]." U. S. 1880.

liquids, widening as the tube is gently shaken. The Solution should not effervesce when shaken carefully with *sodium bicarbonate* (absence of acid). 10 cubic centimetres, mixed with 5 cubic centimetres of the *volumetric solution of sodium hydroxide* and 5 cubic centimetres of *water*, should not assume a yellow color (absence of aldehyde). 1 volume, agitated briskly at intervals during five minutes in a brine-charged nitrometer with 1 volume of *solution of potassium iodide* and 1 volume of *diluted sulphuric acid*, should yield, at the ordinary temperature (60° F. or 15.5° C.) and pressure (30 inches or 760 millimetres of mercury), and when freshly prepared, at least 7.6 volumes of nitric oxide gas; and even after the Solution has been kept for some time, and the vessel containing it has occasionally been opened, it should possess at least five-sixths of the strength just indicated. Solution of Ethyl Nitrite should be stored in small bottles." *Br.* This preparation affords a means of giving ethyl nitrite internally.

Dose, from twenty to sixty minims (1.3 to 3.75 Cc.). (See *Spiritus Ætheris Nitrosi*.)

LIQUOR FERRI ACETATIS. *Br.*

SOLUTION OF FERRIC ACETATE

(Liquor fēr'ri āc-ē-tā'tis)

Solution of Acetate of Iron; Solution of Peracetate of Iron; Liquor Ferri Acetici; Liqueur d'Acétate de Fer, Acétate Ferrique liquide, *Fr.*; Ferriacetatlösung, Essigsäure Eisen-Flüssigkeit, *G.*

"Solution of Ferric Sulphate, $2\frac{1}{2}$ fl. ounces (Imperial measure) or 125 cubic centimetres; Solution of Ammonia, 4 fl. ounces (Imp. meas.) or 200 cubic centimetres or a sufficient quantity; Glacial Acetic Acid, liquefied, $1\frac{1}{2}$ fl. ounces (Imp. meas.) or 75 cubic centimetres; Distilled Water, a sufficient quantity. Mix the Solution of Ammonia with one pint (Imp. meas.) or one litre of Distilled Water; gradually add to this the solution of Ferric Sulphate diluted with one pint (Imp. meas.) or one litre of Distilled Water; stir well together, taking care that ammonia is, even finally, in slight excess, as indicated by the odor of the mixture; let the whole stand for two hours, stirring occasionally; transfer it to a calico filter; wash the precipitated ferric hydroxide with Distilled Water until free from sulphates; let it drain; squeeze it to remove superfluous moisture; dissolve it in the Glacial Acetic Acid; make the volume up to one pint (Imp. meas.) or one litre with Distilled Water; allow any insoluble matter to subside; pour off the clear Solution." *Br.* The U. S. P. (8th Rev.) very properly dismissed this solution as it is very rarely used in America and it is not a stable preparation of iron. The U. S. 1890 process is appended.¹

¹ *Liquor Ferri Acetatis, Solution of Ferric Acetate*.—"An aqueous solution of Ferric Acetate [$\text{Fe}_2(\text{C}_2\text{H}_3\text{O}_2)_6 = 464.92$], containing about 31 per cent. of the anhydrous salt, and corresponding to about 7.5 per cent. of metallic iron." U. S. 1890.

The formula of this preparation is practically identical with that of the solution of iron acetate of the former German Pharmacopœia. The British process consists in first forming ferric hydroxide, by precipitating a solution of ferric sulphate with ammonia water, washing and draining the precipitate, and finally dissolving it in glacial acetic acid. The solution is readily effected in the cold, and no heat whatever should be used, to avoid decomposition. It is impossible to prevent change, however, by time, an insoluble precipitate invariably making its appearance. The former German Pharmacopœia directed diluted acetic acid, and its *Liquor Ferri Subacetici* was not so strong as the U. S. P. 1890 solution, having only the sp. gr. 1.087 to 1.091, corresponding to 5 per cent. of iron. The British preparation (sp. gr. 1.031) is still weaker. The strong solution of acetate of iron (*Br. Ph.* 1885) is no longer official. (See U. S. D., 17th ed., 798.)

Properties.—The solution of the U. S. P. 1890 was described as "a dark reddish-brown, clear liquid, of an acetous odor, a sweetish, acidulous, somewhat styptic taste, and a slightly acid reaction. Specific gravity, about 1.160 at 15° C. (59° F.). The diluted Solution yields a brownish-red precipitate with ammonia water, and a blue one with potassium ferrocyanide test-solution. When heated to boiling, the Solution yields a brownish-red precipitate, and when heated with sulphuric acid, it emits acetous vapors. If the iron be completely precipitated from a portion of the Solution by an excess of ammonia water, the filtrate should be colorless, and should not yield a white or dark-colored precipitate with hydrogen sulphide test-solution (absence of zinc or copper), nor should it leave a residue on evapo-

"Solution of Ferric Sulphate, one thousand grammes [or 35 ounces av., 120 grains]; Glacial Acetic Acid, two hundred and sixty grammes [or 9 ounces av., 75 grains]; Ammonia Water, eight hundred and fifty cubic centimeters [or 28 fluidounces, 356 minims]; Water, Distilled Water, each, a sufficient quantity, to make one thousand grammes [or 35 ounces av., 120 grains]. Mix the Ammonia Water with three thousand cubic centimeters [or 101 fluidounces, 213 minims] of cold Water, and the solution of Ferric Sulphate with ten thousand cubic centimeters [or 338 fluidounces, 70 minims] of cold Water. Add the latter solution slowly to the diluted Ammonia Water, stirring constantly. Let the mixture stand until the precipitate has subsided as far as practicable, and then decant the supernatant liquid. Add to the precipitate six thousand cubic centimeters [or 202 fluidounces, 426 minims] of boiling Water, mix well, and again set the mixture aside, as before. Repeat the washing with successive portions of boiling Water, in the same manner, until the washings are no longer affected by sodium cobaltic nitrite test-solution (showing the removal of ammonia and its salts). Transfer the mixture to a wet muslin strainer, allow the precipitate to drain completely, and press it, folded in the strainer, until its weight is reduced to seven hundred grammes [or 24 ounces av., 303 grains] or less. Now add the precipitate gradually to the Glacial Acetic Acid contained in a tared jar provided with a glass stopper, stirring the mixture after each addition until each portion added is nearly dissolved before adding another portion. Finally, add enough Distilled Water to make the product weigh one thousand grammes [or 35 ounces av., 120 grains], mix thoroughly, allow it to become clear by subsidence, and decant the clear solution. Keep the product in well-stoppered bottles, in a cool place, protected from light." U. S. 1890.

ration and gentle ignition (absence of salts of the fixed alkalis). If to a small portion of the Solution, diluted with about 10 volumes of water, a few drops of freshly prepared potassium ferrieyanide test-solution be added, a pure brown color should be produced, without a tinge of green or greenish-blue (absence of ferrous salt). If 1.12 (1.1176) Gm. of the Solution be introduced into a glass-stoppered bottle (having a capacity of about 100 Cc.), together with 15 Cc. of water and 2 Cc. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch test-solution, it should require about 15 Cc. of sodium hyposulphite decinormal volumetric solution to discharge the blue or greenish color of the liquid (each Cc. of the volumetric solution indicating 0.5 per cent. of metallic iron)." U. S. 1890. "A red liquid with a sour styptic taste and acetous odor, miscible with water and alcohol (90 per cent.) in all proportions. It affords the reactions characteristic of ferric salts and of acetates. It should not yield any characteristic reaction with the tests for lead, copper, arsenium, zinc, calcium, sodium, potassium, ammonium, nitrates, or ferrous salts, and only very slight reactions with the tests for sulphates. Specific gravity 1.031." Br.

Uses.—Ferric acetate is an excellent chalybeate; this solution is not so well adapted for internal administration as is the tincture of ferric acetate or the solution of iron and ammonium acetate. It was introduced into a former Pharmacopœia for the purpose of making the tincture, but it was rarely used; it may be serviceable when mixed with water, with the addition of an aromatic syrup.

Dose, from two to ten minims (0.12 to 0.6 Cc.).

LIQUOR FERRI CHLORIDI. U. S. (Br.)

SOLUTION OF FERRIC CHLORIDE

(li'quor fēr'ri chlō'rī-di)

"An aqueous solution of Ferric Chloride, which should contain not less than 29 percent. of the anhydrous salt [$\text{FeCl}_3 = 161.04$], corresponding to 10 percent. of metallic iron." U. S. "110 minims contain 22½ grains of Iron; 100 cubic centimetres contain 22.5 grammes." Br.

Liquor Ferri Perchloridi Fortis, Br. Liquor Ferri Muriatici Oxidati, Strong Solution of Ferric Chloride, Solution of Chloride of Iron; Chlorure Ferrique dissous, Fr. Cod.; Soluté de Perchlorure de Fer, Chlorure Ferrique liquide, Fr.; Liquor Ferri Sesquichlorati, P. G.; Flüssiges Eisenchlorid, Eisenchloridlösung, G.; Solucion de Cloruro Ferrico, Sp.

* "Iron, in the form of fine, bright wire, and cut into small pieces, one hundred and twenty-five grammes [or 4 ounces av., 179 grains]; Hydrochloric Acid, six hundred and eighty grammes [or 23 ounces av., 432 grains]; Nitric Acid, Distilled Water, each, a sufficient quan-

tity, to make one thousand grammes [or 35 ounces av., 120 grains]. Introduce the Iron Wire into a flask having a capacity of about two thousand cubic centimetres [or 67 fluid-ounces, 301 minims], pour upon it a mixture of four hundred and twenty grammes [or 14 ounces av., 357 grains] of Hydrochloric Acid and two hundred and fifty cubic centimetres [or 8 fluidounces, 218 minims] of Distilled Water, and heat upon a water-bath for not less than one hour and fifteen minutes, or until effervescence ceases; then boil the liquid, filter it through paper, and, having rinsed the flask and Iron Wire with a little hot Distilled Water, pass the rinsings through the filter. To the filtered liquid add two hundred and twenty grammes [or 7 ounces av., 333 grains] of Hydrochloric Acid, add the mixture slowly and gradually, in a stream, to sixty-five grammes [or 2 ounces av., 128 grains] of Nitric Acid contained in a capacious porcelain vessel, and warm gently. After effervescence ceases, apply heat, by means of a sand-bath, stirring occasionally, until the liquid is free from Nitric Acid. If the solution has acquired a black color, continue the addition of Nitric Acid, drop by drop, until red fumes are no longer evolved and the solution assumes a clear reddish-brown color. Finally, add the remaining forty grammes [or 1 ounce av., 180 grains] of Hydrochloric Acid and enough Distilled Water to make the Solution weigh one thousand grammes [or 35 ounces av., 120 grains]." U. S.

"Iron, 4 ounces (Imperial) or 80 grammes; Hydrochloric Acid, 20½ fl. ounces (Imp. meas.) or 410 cubic centimetres; Nitric Acid, 1½ fl. ounces (Imp. meas.) or 30 cubic centimetres; Distilled Water, a sufficient quantity. Place the Iron in a flask; add a mixture of twelve and a half fluid ounces (Imp. meas.) or two hundred and fifty cubic centimetres of Hydrochloric Acid and seven [fluid] ounces (Imp. meas.) or one hundred and forty cubic centimetres of Distilled Water; expose to a moderate temperature until effervescence ceases; then boil; filter from undissolved Iron; rinse the flask and contents with a little Distilled Water; pour the rinsings over the filter; add to the filtrate seven fluid ounces (Imp. meas.) or one hundred and forty cubic centimetres of Hydrochloric Acid; mix; pour the solution in a slow continuous stream into the Nitric Acid, chemical action being promoted if necessary by the application of slight heat; evaporate the product until no more nitrous fumes escape and a precipitate begins to form; add one fluid ounce (Imp. meas.) or twenty cubic centimetres of Hydrochloric Acid, and sufficient Distilled Water to produce seventeen and a half fluid ounces (Imp. meas.) or three hundred and fifty cubic centimetres of the Solution." Br. (See *Liquor Ferri Perchloridi*, p. 716.) The strength of solution of ferric chloride U. S. P. (8th Rev.) was reduced from the former standard of 13 per cent. of iron

(U. S. P. 1890) to 10 per cent. of iron, which corresponds to the solution of the German Pharmacopœia; this strength is sufficient for all purposes, and is more convenient for calculations. The British preparation contains 15.84 per cent. of iron. By the reaction between the hydrochloric acid and the iron, ferrous chloride is produced, which by the subsequent agency of the hydrochloric and nitric acids is converted into ferric chloride, or, as it is denominated in the British Pharmacopœia, perchloride of iron, this being retained in solution by the water with the excess of acid. This preparation was included in the original British Pharmacopœia, but was not official with us until 1870. The original British formula (1864) was defective in several respects. For an account of these see the 13th edition of this book. The formula for the present British solution has been modelled after that of the U. S. Pharmacopœia.

When iron is treated with hydrochloric acid there is a copious evolution of hydrogen, and an emerald-green solution of ferrous chloride (FeCl_2) results. Green crystals having the composition $\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$ separate if the solution is permitted to rest. In the official process, water is added to the hydrochloric acid in order to retain the crystals in solution, and the mixture is heated while still in contact with the excess of iron, in order to hasten the complete conversion of all the hydrochloric acid into ferrous chloride. The action slackens very materially as the quantity of hydrochloric acid is gradually lessened in the mixture, but when it is brought, as officially directed, to the boiling point, a saturated solution is produced. After filtering from the excess of iron, half the original quantity of hydrochloric acid is added,—this for the purpose of supplying the amount which is requisite to form the solution of ferric chloride,—and the mixture is then gradually poured into nitric acid, which at once converts the solution of green ferrous chloride into the solution of red ferric chloride. Formerly the nitric acid was added to the solution; now the order is reversed, in accordance with the recommendation of C. L. Diehl, to prevent frothing. (See *A. J. P.*, 1867, p. 140.) The reaction between the acids and the solution may be thus expressed:

If the solution should have a blackish color, and not a clear ruby-red, it is due to the presence of a nitro-compound composed of a portion of ferrous chloride and nitrogen dioxide, $\text{FeCl}_2 + \text{N}_2\text{O}_2$. As this compound is easily decomposed, all that is necessary is to heat the liquid and add a few drops of nitric acid, when the blackish color soon disappears, nitrogen dioxide is liberated, and a ruby-red solution remains. Any excess of nitric acid is to

be evaporated off.¹ The final addition of hydrochloric acid is to compensate for any loss which may have been suffered by heating the solution, and to secure an excess of the acid in the finished preparation; otherwise a reddish-brown deposit of oxychloride would gradually form, and precipitation would result upon dilution with alcohol in making the official tincture.

The solution of ferric chloride, properly made, is "a reddish-brown liquid, having a faint odor of hydrochloric acid, an acid, strongly styptic taste, and an acid reaction. Specific gravity: about 1.282 at 25° C. (77° F.). The diluted Solution yields a brownish-red precipitate with ammonia water, a blue one with potassium ferrocyanide T.S., and a white one, insoluble in nitric acid, with silver nitrate T.S. If the iron be completely precipitated from a portion of the Solution by an excess of ammonia water, the filtrate should be colorless, and should not yield a precipitate with hydrogen sulphide T.S. (absence of zinc or copper); nor should it leave a fixed residue on evaporation and gentle ignition (absence of salts of the fixed alkalis). On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and a diluted portion of the Solution (1 in 10), the crystal should not become colored brown, nor should a brownish-black color develop around it (absence of nitric acid). If to a diluted portion of the Solution (about 1 in 20) a few drops of freshly prepared potassium ferricyanide T.S. be added, a pure brown color should be produced, which should not at once turn green or greenish-blue (absence of ferrous salts). If to 3 drops of Solution of Ferric Chloride, 10 Cc. of tenth-normal sodium thiosulphate V.S. be added, and then slowly heated to boil-

¹ The use of chlorine instead of nitric acid for converting the ferrous chloride to the ferric condition is advocated by C. W. Weiss (*Ph. Ztg.*; *N. R.*, 1883, p. 247), and J. W. England has devised the following process, based upon such substitutions, which is alleged to furnish a purer product:

"Take of Iron, in the form of fine wire, and cut in small pieces, 15 parts (3½ oz. av.); Hydrochloric Acid, 59 parts (14¼ oz. av.); Chlorine Gas, Distilled Water, each, a sufficient quantity to make 100 parts (25 oz. av.). Place the Iron Wire in a capacious flask, and pour upon it 54 parts (13½ oz. av.) of Hydrochloric Acid, previously diluted with 25 parts (6¼ oz. av., or 6 fluidounces) of Distilled Water. Heat the liquid slowly, until the reaction is ended, and effervescence ceases; then rapidly heat to the boiling point, filter through paper, and, having rinsed the flask and residue with a little boiling distilled water, pass the washings through the filter. To the filtrate add immediately 5 parts (1¼ oz. av.) of Hydrochloric Acid, followed by the addition of 20 parts (5 oz. av.) of boiling Distilled Water. Keep the liquid nearly boiling, and pass through it a stream of gaseous chlorine (generated in the usual way), agitating occasionally, until a small portion, tested with freshly-prepared potassium ferricyanide test-solution, gives no indication of the existence of a ferrous compound by producing a blue precipitate. Lastly, add, after any free chlorine present has been removed by heat, sufficient distilled water to make the whole product weigh 100 parts (25 oz. av.)." (*A. J. P.*, 1885, p. 113.) August Drescher (*D. C.*, 1887, p. 4) proposes the use of hydrogen dioxide (H_2O_2), now an article of commerce, as a substitute for either nitric acid or chlorine.

ing, no brownish-red precipitate of ferric hydroxide should separate (absence of *oxychloride*). If 10 Gm. of the Solution be diluted to measure 100 Cc., and 11.1 Cc. of this be introduced into a glass-stoppered bottle (having a capacity of about 100 Cc.), together with 10 Cc. of water and 2 Cc. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch T.S., it should require not less than 20 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the blue or greenish color of the liquid (each Cc. of the tenth-normal sodium thiosulphate V.S. indicating 0.5 percent. of metallic iron)." U. S. Water and alcohol unite with it in all proportions. The British preparation (*Liquor Ferri Perchloridi Fortis*) is stronger than the U. S. official, the sp. gr. of the former being 1.420 at 15.5° C. (60° F.), of the latter 1.282 at 25° C. (77° F.) it should be remembered, however, that there is in the British Pharmacopœia, another solution of ferric chloride which is weaker; it has the sp. gr. 1.110 and is termed *Liquor Ferri Perchloridi*. (See page 716.) "An orange-brown solution with a strong styptic taste, miscible with water and alcohol in all proportions. It affords the reactions characteristic of ferric salts and chlorides, and should not yield any characteristic reaction with the tests for lead, copper, arsenium, zinc, calcium, sodium, potassium, ammonium, nitrates, or ferrous salts. Specific gravity about 1.42. 5 cubic centimetres of it diluted with 80 cubic centimetres of water should give, upon the addition of an excess of solution of ammonia, a reddish-brown precipitate which when well washed and incinerated, weighs 1.6 grammes.¹ 110 minims contain 22½ grains of Iron; 100 cubic centimetres contain 22.5 grammes." Br.

From the experiments of Adrian it appears that sugar has the property when mixed in certain proportions with solution of ferric chloride of converting it partly into ferrous chloride. The alteration commences immediately on the addition of sugar, as shown by the deeper color of the liquid; after some hours potassium ferri cyanide will indicate the presence of a ferrous salt, and after twenty-four hours the greater proportion of the ferric salt has undergone the change.² (B. M. S. J., March, 1868.)

¹ F. C. J. Bird calls attention to the fact that when the British Pharmacopœia process for preparing strong solution of ferric chloride is strictly adhered to the final product will contain a quantity of ferric chloride corresponding to 1.44 Gm. Fe₂O₃ per 5 Cc. Instead of 1.6 Gm. required. The specific gravity (about 1.42) also does not conform to a solution yielding 1.60 Gm. ferric oxide per 5 Cc., such a solution having the sp. gr. 1.488 at 15.5° C. To obtain such a solution the formula must be modified on lines pointed out by the author. (Y. B. P., 1899, 361-362.)

² The solution of ferric chloride, when kept, has a disposition to deposit the insoluble oxychloride of iron, and the resulting excess of hydrochloric acid is injuriously irritating. To obviate this disadvantage, Burlin du Buisson recommends the following

Uses.—This preparation was brought prominently into notice by Pravaz, a surgeon of Lyons, who found that a few drops of a strong solution, injected into a blood vessel, produced coagulation of all the blood in the vessel for the extent of an inch or more. Its use as a styptic was the natural result of this observation. In this capacity it has been used in the cure of *varices*, and has even been recommended as an injection in ordinary *aneurisms*. In arresting hemorrhages from cut surfaces or wounded vessels it has proved remarkably successful. It has also been found advantageous as an application to *nasal polypi*, *erectile tumors*, or *navi materni* in infants, in *ulcers* about the nails, and in various cutaneous affections. (See *Ferric Chloride*.) Attempts have been made to cure *navi materni* by the injection of the solution into the erectile tumor, but this proceeding is hazardous and has caused death. (*Ann. Thér.*, 1867, p. 117.) It has been used externally with asserted success in *varicose veins*. It may be used internally, properly diluted, for the general purposes of chalybeates, and especially as a substitute for the tincture of ferric chloride, when the alcohol of that preparation is objectionable. In *post-partum hemorrhage* it has been largely employed, a solution of it, varying in strength from a drachm to a half ounce to the pint, being thrown directly into the relaxed uterus. It is used in preparing tincture of ferric chloride.

Dose, one to five minims (0.06 to 0.3 Cc.).

Off. Prep.—Ferri Chloridum, U. S.; Liquor Ferri Perchloridi, Br.; Tinctura Ferri Chloridi, U. S. (Br.).

LIQUOR FERRI ET AMMONII ACETATIS. U. S.

SOLUTION OF IRON AND AMMONIUM ACETATE [Basham's Mixture]

(*Li'quor fēr'ri ēt ām-mō'nī-i āc-q-tā'tis*)

Mistura Ferri et Ammonii Acetatis, U. S. P. 1880.

* "Tincture of Ferric Chloride, *forty cubic centimeters* [or 1 fluidounce, 169 minims];

mode of preparation. "Saturate as quickly as possible pure and colorless hydrochloric acid with [gelatinous] hydrated ferric oxide; evaporate the solution to somewhat less than one-half over a gentle fire; and then continue the evaporation by means of the waterbath, taking care to remove the aqueous vapors, which would cause the formation of hydrochloric acid, and a deposition of insoluble oxychloride. When the solution has attained the consistence of thick syrup (in which state it curdles on cooling, without, however, becoming a solid mass), cease evaporating, add an excess of the gelatinous hydrate diluted with a little water, agitate for a quarter of an hour, and afterwards allow the liquor to rest for several hours. Next add distilled water sufficient to bring the solution to the density of 30° Baumé, and allow it to stand for eight days in contact with an excess of the hydrate; after which filter, and again allow it to stand for two weeks." This strength of the solution is required for the cure of *varices*. For injection into *aneurismal tumors* it is sufficient to employ a solution of 20° or even 15°. These degrees of Baumé correspond to the following percentages, 30° to 29.70 per cent. of the dry salt, 20° to 17.05 per cent., and 15° to 12.10 per cent. (See *Ferri Chloridum*.)

Diluted Acetic Acid, *sixty cubic centimeters* [or 2 fluidounces, 14 minims]; Solution of Ammonium Acetate, *five hundred cubic centimeters* [or 16 fluidounces, 435 minims]; Aromatic Elixir, *one hundred and twenty cubic centimeters* [or 4 fluidounces, 28 minims]; Glycerin, *one hundred and twenty cubic centimeters* [or 4 fluidounces, 28 minims]: Water, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. To the Solution of Ammonium Acetate (which should not be alkaline) add, successively, the Diluted Acetic Acid, the Tincture of Ferric Chloride, the Aromatic Elixir, and the Glycerin, and lastly, enough Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. This preparation should be freshly made when wanted." *U. S.*

The first name of this preparation has been changed to "Liquor" in accordance with the views expressed in the 16th edition of this work, as it belongs to the class of solutions, and is not a mixture in the modern acceptation of the term. The formula has been improved by the addition of glycerin, which enables the solution to remain undecomposed somewhat longer, and by the increase in strength; the amount of active ingredients in the *U. S. P.* (8th Rev.) being double that of the former Pharmacopœia. It should be borne in mind, however, that this was never intended to be a permanent solution, and in time precipitation and decomposition surely set in. Some pharmacists adopt the plan of keeping all the ingredients, except the tincture of ferric chloride and water, mixed together in advance, and when called upon to dispense the solution, to add the proper quantity of tincture and water; this saves time and enables them to dispense a clear solution. When freshly made, it is a transparent, bright red liquid. When cloudy, the absence of sufficient free acid is indicated. The iron is in the form of an acetate, while there is formed, as one of the products of decomposition, a small quantity of ammonium chloride, the larger proportion of ammonium acetate remaining undecomposed. Basham's mixture is actively chalybeate, and also astringent, and is very largely used in *chronic Bright's disease*.

Dose, from one-fourth to one-half fluidounce (7.5 to 15 Cc.).

LIQUOR FERRI PERCHLORIDI. Br.

SOLUTION OF PERCHLORIDE OF IRON

(lī'quor fēr'ri pēr-čhlō'rī-dī)

Solution of Ferric Chloride.

"Strong Solution of Ferric Chloride, 5 *fl. ounces* (Imperial measure) or 250 cubic centimetres; Distilled Water, a *sufficient quantity*. Mix the Strong Solution of Ferric Chloride with sufficient Distilled Water to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of this Solution of Ferric Chloride." *Br.* (See p. 714.)

This is one-fourth the strength of the *Liquor Ferri Perchloridi* of the *Br. Pharmacopœia* of 1864, which is the *Liquor Ferri Perchloridi Fortis* of the present edition. (See p. 713.) It is of the same ferruginous strength as the British Tincture of Ferric Chloride. The specific gravity of this solution is 1.110, and it may be substituted for the tincture of ferric chloride when alcohol is objectionable, as it has the same strength; it is very astringent, and is perhaps less active as a diuretic than the tincture.

Dose, from ten to thirty minims (0.6 to 1.8 Cc.) well diluted.

LIQUOR FERRI PERNITRATIS. Br.

SOLUTION OF FERRIC NITRATE

(lī'quor fēr'ri pēr-nī-trā'tis)

Solution of Pernitrate of Iron: Azotate (Pernitrate) de Fer liuide, *Fr.*; Eisennitratlösung, *Ferrin*-nitratlösung, *Salpetersaure Eisenoxyd-Lösung*, *G.*

"Iron, 1 *ounce* (Imperial) or 20 grammes; Nitric Acid, 4½ *fl. ounces* (Imp. meas.) or 90 cubic centimetres; Distilled Water, a *sufficient quantity*. Dilute the Nitric Acid with sixteen [*fluid*] *ounces* (Imp. meas.) or three hundred and twenty cubic centimetres of the Distilled Water; introduce the Iron; set aside until the metal is dissolved, taking care to moderate the action, should it become too violent, by the addition of a little more Distilled Water; filter the liquid; add enough Distilled Water to produce *thirty fluid ounces* (Imp. meas.) or six hundred cubic centimetres of the Solution." *Br.*

This solution was dropped by the *U. S. P.* (8th Rev.); the formula of the *U. S. P.* 1890 is appended.¹ Solution of ferric nitrate was made in the *U. S. P.* 1870 by first forming

¹ *Liquor Ferri Nitratis*, *Solution of Ferric Nitrate*, *U. S. 1890*.—"An aqueous solution of Ferric Nitrate [$\text{Fe}_2(\text{NO}_3)_6 = 483.1$], containing about 6.2 per cent. of the anhydrous salt, and corresponding to about 1.4 per cent. of metallic iron." *U. S. 1890*.

"Solution of Ferric Sulphate, *one hundred and eighty grammes* [or 6 ounces av., 153 grains]; Ammonia Water, *one hundred and sixty cubic centimeters* [or 5 fluidounces, 197 minims]; Nitric Acid, *seventy-one grammes* [or 2 ounces av., 220 grains]; Distilled Water, Water, each, a *sufficient quantity*, to make *one thousand grammes* [or 35 ounces av., 120 grains]. Mix the Ammonia Water with *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of cold Water, and the Solution of Ferric Sulphate with *fifteen hundred cubic centimeters* [or 50 fluidounces, 345 minims] of cold Water. Add the latter solution slowly to the diluted Ammonia Water, with constant stirring. Let the mixture stand until the precipitate has subsided as far as practicable, and then decant the supernatant liquid. Add to the precipitate *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of cold Water, mix well, and again set the mixture aside, as before. Repeat the washings with successive portions of cold Water, in the same manner, until the washings produce but a slight cloudiness with barium chloride test-solution. Pour the washed ferric hydrate on a wet muslin strainer, and let it drain thoroughly. Then transfer it to a porcelain capsule, add the Nitric Acid, and stir with a glass rod, until a clear solution is obtained. Finally, add enough Distilled Water to make the finished product weigh *one thousand grammes* [or 35 ounces av., 120 grains]. Filter, if necessary." *U. S. 1890*.

ferrous nitrate by dissolving iron wire in diluted nitric acid, and then converting this into ferric nitrate by heating with an additional quantity of nitric acid; there was a slight excess of nitric acid left in the solution (about 1.4 per cent.). It was believed by the Committee of Revision of the U. S. P. 1890 that a solution of more definite composition would be made by adopting Louis Dohme's process. In this, ferric hydroxide is dissolved in nitric acid in such proportion that the solution of ferric nitrate shall contain 6.2 per cent. of the anhydrous salt when assayed by the official process, and about 1 per cent. of free nitric acid.¹

Properties.—The U. S. (1890) solution was "a clear amber-colored or reddish liquid, odorless, having an acid, styptic taste, and an acid reaction. Specific gravity, about 1.050 at 15° C. (59° F.). The Solution gives a brownish-red precipitate with ammonia water, and a blue one with potassium ferrocyanide test-solution. If a clear crystal of ferrous sulphate be added to a cooled mixture of equal parts of the Solution and of concentrated sulphuric acid, the crystal will become brown and be surrounded by a brownish-black zone. If 1.12 (1.1176) Gm. of the Solution be introduced into a glass-stoppered bottle (having a capacity of about 100 Cc.), together with 15 Cc. of water and 2 Cc. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch test-solution, it should require about 2.8 Cc. of sodium hyposulphite decinormal volumetric solution to discharge the blue or greenish color of the liquid (each Cc. of the volumetric solution indicating 0.5 per cent. of metallic iron)." U. S. 1890.

It contains no ferrous nitrate, and does not give a blue precipitate with potassium ferrocyanide. The British preparation is described as "a clear solution of a reddish-brown color, distinctly acid and astringent to the taste. It affords the reactions characteristic of ferric salts and of nitrates. It should not yield any characteristic reaction with the tests for lead, copper, arsenium, zinc, calcium, sodium, potassium, ammonium, chlorides, sulphates, or ferrous salts. Specific gravity 1.107. 5 cubic centimetres treated with an excess of solution of ammonia should give a precipitate which, when washed, dried, and incinerated, weighs 0.23 gramme. 110 minims contain 3½ grains of Iron; 100 cubic centimetres contain 3.3 grammes." Br. It is, therefore, about twice as strong as the U. S. Pharm. 1890 solution.

Ferric nitrate is somewhat deliquescent, very soluble in water, and sparingly soluble in nitric acid. It consists of the double atom of iron,

Fe₂, which is hexatomic, combined with 6 groups, NO₃, and crystallizes either with 12 molecules of water in colorless cubes, or with 18 molecules of water in colorless monoclinic crystals, yielding, therefore, either Fe₂(NO₃)₆ + 12H₂O or Fe₂(NO₃)₆ + 18H₂O.

Uses.—This astringent chalybeate was introduced to the notice of the profession by William Kerr, in 1832, and has been commended in *atonic chronic diarrhœa*, and even in *mucous diarrhœa* attended with pain, but without ulcerations of the intestines; in our experience it has seemed to be irritating, and has generally failed to accomplish good. It has also been used with alleged good effect in *menorrhagia*, and both internally and by injection in *leucorrhœa*, when occurring in pale, exsanguine, and feeble subjects; it should be sufficiently diluted to cause only a slight heat and smarting in the vagina.

Dose, according to Graves, is five or six minims (0.3 to 0.4 Cc.), gradually increased to fifteen minims (0.9 Cc.), sufficiently diluted, given in the course of the day. Garrod and Squire state the dose of the British preparation as from thirty minims to a fluidrachm (1.8 to 3.75 Cc.). Considering that a fluidrachm (3.75 Cc.) of the British solution contains 7.865 grains (0.49 Gm.) of the salt, this appears to us a very large dose.

LIQUOR FERRI SUBSULPHATIS. U. S.

SOLUTION OF FERRIC SUBSULPHATE [Solution of Basic Ferric Sulphate, Monsel's Solution]

(lí'quor fēr'ri sūb-sŭl-phā'tis)

"An aqueous solution of variable chemical composition, containing an amount of basic ferric sulphate corresponding to not less than 13.57 percent. of metallic iron." U. S.

Solution of Subsulphate of Iron; Solution of Persulphate of Iron; Liqueur hémostatique de Monsel, Fr.; Basisch-schwefelsaure Eisenoxydlösung, Monsel's Eisenlösung, Monseische Eisenlösung, G.

* "Ferrous Sulphate, in clear crystals, six hundred and seventy-five grammes [or 23 ounces av., 284 grains]; Sulphuric Acid, sixty-five grammes [or 2 ounces av., 128 grains]; Nitric Acid, Distilled Water, each, a sufficient quantity, to make one thousand grammes [or 35 ounces av., 120 grains]. Add the Sulphuric Acid to five hundred cubic centimeters [or 16 fluidounces, 435 minims] of Distilled Water in a capacious porcelain dish, heat the mixture to nearly 100° C. (212° F.), then add seventy grammes [or 2 ounces av., 205 grains] of Nitric Acid, and mix well. Divide the Ferrous Sulphate, coarsely powdered, into four equal portions, and add these portions, one at a time, to the hot liquid, stirring after each addition until effervescence ceases. If, after the Ferrous Sulphate has been dissolved, the solution is of a black color, add Nitric Acid, a few drops at a time, with heating and stir-

¹ Syrup of Ferrous Nitrate may be prepared by Procter's formula. (See U. S. D., 16th ed., p. 903.)

ring, until it no longer causes red fumes to be evolved; then boil the Solution until it assumes a ruby-red color and is free from Nitric Acid. Lastly, add enough Distilled Water to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains]. Filter if necessary. Keep it in well-stoppered bottles, in a moderately warm place (not under 22° C. or 71.6° F.), protected from light. This solution sometimes crystallizes, forming a semi-solid, whitish mass. When this occurs, the application of a gentle heat to the bottle will restore the liquid condition." *U. S.*

This process is essentially that of E. R. Squibb. The object is to obtain in solution *Monse's Persulphate of Iron*, improperly so called, as it differs both in composition and in properties from the salt of iron properly named persulphate. The composition of the true persulphate is $\text{Fe}_2(\text{SO}_4)_3$, and it is a neutral salt, while Monse's persulphate has the composition $5\text{Fe}_2(\text{SO}_4)_3 \cdot \text{Fe}_2(\text{HO})_6$,¹ and is properly a subsalt, as it is very appropriately designated in the *U. S. Pharmacopœia*. With this preliminary explanation, the process will be easily understood.

In its preparation the ferrous sulphate is converted into ferric sulphate at the expense of the nitric acid; but the sulphuric acid, mixed with the nitric, is in quantity insufficient to form the normal salt. The sesquioxide is therefore but partially saturated, and a subsalt results, having the constitution above mentioned.²

Properties.—The solution of ferric subsulphate is "a dark reddish-brown liquid, odorless or nearly so, of an acid, strongly styptic taste, and an acid reaction. Specific gravity: about 1.548 at 25° C. (77° F.). Miscible with water and alcohol, in all proportions, without decomposition. The diluted Solution yields a brownish-red precipitate with ammonia water, a blue one with potassium ferrocyanide T.S., and a white one, insoluble in hydrochloric acid, with barium chloride T.S. On slowly mixing

2 volumes of the Solution with 1 volume of concentrated sulphuric acid, in a beaker, a semi-solid white mass should separate on standing (difference from *tersulphate*). On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and a diluted portion of the Solution (about 1 in 10), the crystal should not become brown, nor should a brownish-black color develop around it (absence of *nitric acid*). If to a diluted portion of the Solution (1 in 20), a few drops of freshly prepared potassium ferriocyanide T.S. be added, a pure brown color should be produced; it should not at once turn green or greenish-blue (absence of *ferrous salt*). If 10 Gm. of the Solution be diluted to measure 100 Cc., and 11.1 Cc. of this be introduced into a glass-stoppered bottle (having a capacity of about 100 Cc.), with 10 Cc. of water and 2 Cc. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at the temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch T.S., it should require not less than 27.2 (27.15) Cc. of tenth-normal sodium thiosulphate V.S. to discharge the blue or greenish color of the liquid (each Cc. of the tenth-normal sodium thiosulphate V.S. indicating 0.5 percent. of metallic iron)." *U. S.* A little sulphuric acid decolorizes the liquid in a considerable degree, and an excess of the same acid converts it into a white, soft, pasty solid, resembling plaster of Paris which has begun to solidify after mixture with water. This test, according to Squibb, is quite characteristic. (*N. Y. Journ. Med.*, 1860, p. 173.)

By evaporation, upon a glass surface, with a moderate heat, the solution yields ferric subsulphate, or *Monse's salt*, in the form of thin transparent scales, of a light reddish-brown color, deliquescent, and readily soluble in water. Attention was first called to the special styptic virtues of ferric sulphate by Monse in 1852; but it was not until 1857 that he published the formula for the peculiar salt which now goes by his name, and the solution of which is the subject of the present article. (See *J. P. C.*, Sept. 1857; also *Ibid.*, Juillet, 1859.)

Uses.—In consequence of its deficiency of sulphuric acid, this salt is less irritant than the ferric sulphate, while it has at least equal, if not greater, astringency. It is very efficacious as a styptic, through its power of coagulating the blood. The solution may be applied by means of a small sponge or pencil of spun glass to the bleeding surface or vessel. In cases of *hemoptysis*, a dilution of it (from five to ten minims to the fluidounce) has been used with advantage, by means of the atomizer. It is an excellent styptic in *hemorrhage* from the stomach and bowels.

Dose, from three to six minims (0.2 to 0.4 Cc.), properly diluted, and repeated as often as necessary.

¹ Spencer U. Pickering believes that the true composition of basic ferric sulphate is represented by the formula $\text{Fe}_2(\text{SO}_4)_3 \cdot 5\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$. (See *J. Chem. S.*, xliii, 182.)

² J. Creuse offers the following formulas for the preparation of the solutions of *ferric sulphate* and *ferric subsulphate*, holding them to be superior to the official because they require no special apparatus and generate no noxious vapors:

For the ferric sulphate, take of Ferrous Sulphate, in coarse powder, twelve troyounces; Sulphuric Acid two troyounces and sixty grains; Potassium Chlorate three hundred and forty-eight grains; Boiling Water twelve fluidounces. Dissolve the ferrous sulphate in the boiling water in a glass flask, or in any convenient bottle; add the sulphuric acid gradually, and, while the liquid is hot, add the potassium chlorate by small portions. When all is dissolved, filter, and complete twenty-four fluidounces. The following formula explains the reactions:

For the subsulphate, take of the ingredients above enumerated, respectively, twelve troyounces, one troyounce and thirty grains, three hundred and forty grains, ten fluidounces; proceed as before; evaporate to twelve fluidounces, and filter. (*A. J. P.*, xliii, 169.) The solutions thus obtained contain some potassium chloride.

LIQUOR FERRI TERSULPHATIS.**U. S. (Br.)****SOLUTION OF FERRIC SULPHATE***(li'quor fēr'ri tēr-sul-phā'tis)*

"An aqueous solution, which should contain about 36 percent. of normal Ferric Sulphate [$\text{Fe}_2(\text{SO}_4)_3 = 397.05$], corresponding to not less than 10 percent. of metallic iron." *U. S.*

Liquor Ferri Persulphatis, Br.; Solution of Normal Ferric Sulphate, Solution of Tersulphate of Iron; Solution of Persulphate of Iron; Persulfate de Fer liquide, *Fr.*; Ferrisulfatlösung, Schwefelsaure Eisenoxydlösung, Flüssiges Schwefelsaures Eisenoxyd, *G.*

* "Ferrous Sulphate, in clear crystals, *five hundred grammes* [or 17 ounces av., 279 grains]; Sulphuric Acid, *ninety-six grammes* [or 3 ounces av., 169 grains]; Nitric Acid, Distilled Water, each, *a sufficient quantity*, to make *one thousand grammes* [or 35 ounces av., 120 grains]. Add the Sulphuric Acid to about *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Distilled Water in a capacious porcelain dish, heat the mixture to nearly 100° C. (212° F.), then add *fifty-six grammes* [or 1 ounce av., 427 grains] of Nitric Acid, and mix well. Divide the Ferrous Sulphate, coarsely powdered, into four equal portions, and add these portions, one at a time, to the hot liquid, stirring after each addition until effervescence ceases. When all of the Ferrous Sulphate is dissolved, if the solution has acquired a black color, add Nitric Acid, a few drops at a time, heating and stirring until it no longer causes red fumes to be evolved, and the Solution assumes a clear reddish-brown color; then boil the liquid until it is free from nitric acid. Lastly, add enough Distilled Water to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains]. Filter, if necessary." *U. S.*

"Ferrous Sulphate, 8 ounces (Imperial) or 400 grammes; Sulphuric Acid, 6 fl. drachms (Imp. meas.) or 37.5 cubic centimetres; Nitric Acid, 6 fl. drachms (Imp. meas.) or 37.5 cubic centimetres; Distilled Water, *a sufficient quantity*. Add the Sulphuric Acid to *ten [fluid] ounces* (Imp. meas.) or five hundred cubic centimetres of the Distilled Water; dissolve the Ferrous Sulphate in the mixture with the aid of heat; mix the Nitric Acid with *two [fluid] ounces* (Imp. meas.) or one hundred cubic centimetres of the Distilled Water; add to this diluted acid, warmed, the solution of Ferrous Sulphate; concentrate by boiling, until, by the sudden disengagement of ruddy vapors, the liquid ceases to be black and acquires a red color. If any ferrous salt remain in the solution, add a few drops of Nitric Acid and boil again. When the solution is cold, make up the quantity to *eleven fluid ounces* (Imp. meas.) or five hundred and fifty cubic centimetres by the addition, if necessary, of Distilled Water." *Br.*

The strength of this solution has been increased in the U. S. Pharm. (8th Rev.). The U. S. P. (1890) required a strength equivalent to 8 per cent. of metallic iron, the present Pharmacopœia requires 10 per cent. The ferrous sulphate is directed to be in clear crystals, meaning by this "not effloresced," because when the crystals are coated with a whitish powder they have lost water of crystallization, and the proportion of iron present is variable. The nitric acid in the process gives up enough of its oxygen to convert it entirely into ferric sulphate, and the effervescence is owing to the escape of nitrogen dioxide; this becomes red nitrogen tetroxide by contact with the air. The conversion of the ferrous salt into ferric salt is incomplete until the effervescence ceases, and the color, from black, as it was at first, has become reddish brown. Indeed, in order to convert the whole into ferric sulphate it is necessary to continue the heat until nitrous odor ceases to be evolved, and thus the entire absence of nitric or nitrous acid from the solution is insured. But in consequence of the higher oxidation of the iron the sulphuric acid of the sulphate is insufficient to saturate it. Enough sulphuric acid, therefore, is added to meet this demand. The process is completed by adding enough water to make a definite weight. The U. S. and British formulas are the same in principle.

Properties.—The solution, prepared according to the U. S. formula, is "a dark reddish-brown liquid, almost odorless, having an acid, strongly styptic taste, and an acid reaction. Specific gravity: about 1.432 at 25° C. (77° F.). Miscible with water and alcohol, in all proportions, without decomposition. The diluted Solution yields a brownish-red precipitate with ammonia water, a blue one with potassium ferrocyanide T.S., and a white one, insoluble in hydrochloric acid, with barium chloride T.S. On slowly mixing 2 volumes of the Solution with 1 volume of concentrated sulphuric acid, in a beaker, no solid white mass should separate on standing (difference from *subsulphate*). On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and a diluted portion of the Solution (about 1 in 10), the crystal should not become brown, nor should a brownish-black color develop around it (absence of *nitric acid*). If to a small portion of the Solution, diluted with about 10 volumes of water, a few drops of freshly prepared potassium ferricyanide T.S. be added, a pure brown color should be produced, without a tinge of green or greenish-blue (absence of *ferrous salt*). If 1.11 Gm. of the Solution be introduced into a glass-stoppered bottle (having a capacity of about 100 Ce.), with 15 Ce. of water and 2 Ce. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch T.S.,

it should require not less than 20 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the blue or greenish color of the liquid (each Cc. of the tenth-normal sodium thiosulphate V.S. indicating 0.5 percent. of metallic iron)." U. S. The solution, diluted with water, gives a white precipitate with barium chloride, showing that it contains a sulphate. It keeps well, and we have seen a specimen made by the U. S. 1870 process, ten years old, which retained all its properties unchanged and had deposited nothing. It is described in the Br. Pharmacopœia as "a dense solution of a dark red color, inodorous and very astringent, miscible in all proportions with alcohol and water. It affords the reactions characteristic of ferric salts and of sulphates. It should yield no characteristic reaction with the tests for ferrous salts. Specific gravity 1.441. 5 cubic centimetres diluted with 80 cubic centimetres of water should give, upon the addition of an excess of solution of ammonia, a precipitate which, when well washed and incinerated, weighs 1.04 grammes." Br. Proctor found that a preparation containing 120 grains of sesquioxide to the fluidounce is apt to deposit the anhydrous sulphate on standing.

Uses.—This solution, though powerfully astringent, is too irritant for general use. The chief employment of it is in making other ferruginous preparations in which the ferric hydroxide is wanted, and it should always be kept on hand for the quick preparation of the antidote to arsenic.

Off. Prep.—Ferri et Ammonii Citras, Br.; Ferri et Quinina Citras, Br.; Ferri Hydroxidum, U. S.; Ferri Hydroxidum cum Magnesii Oxido, U. S.; Ferrum Tartratum, Br.; Liquor Ferri Acetatis, Br.

LIQUOR FORMALDEHYDI. U. S.

SOLUTION OF FORMALDEHYDE

(H'quor förm-äl-dē-hy'di)

"An aqueous solution, containing not less than 37 percent., by weight, of absolute Formaldehyde [$\text{H.COH} = 29.79$], an oxidation product of methyl alcohol. It should be kept in well-stoppered bottles, in a cool place, protected from light." U. S.

Formol, Formalin; Soluté d'Aldehyde Formique. Fr.; Formaldehydum solutum, P. G.; Formaldehyd-lösung, G.; Formol, Sp.

Preparation.—Formaldehyde was first prepared in 1868 by Hofmann by passing a mixture of air and methyl alcohol vapor over heated platinum, and it is still practically obtained only from the oxidation of methyl alcohol. This is accomplished in "formaldehyde lamps," or on a larger scale in forms of apparatus such as that described by G. L. Taylor (A. J. P., 1898, 195) as follows: The methyl alcohol to be converted is contained in a circular steel tank, capable of resisting heavy pressure; in the bottom of this tank is placed

a coil of copper pipe into which steam at a high temperature is admitted; by this means the alcohol in the tank is boiled, and the resulting vapor is confined until a pressure of 75 to 80 pounds is reached, when it is allowed to escape into an air-mixer. This mixer is so constructed that an exactly determined quantity of air can be intimately combined with the methyl alcohol vapors. From the mixer the combination of air and vapor passes with great force and velocity through a fine tube into the converter, which has been brought to a dull red heat. This converter consists of two concentric copper tubes, the space between which is filled with broken coke or other material of a similar nature. The inner tube is finely perforated with many small holes. The alcohol vapor is admitted into this inner tube, and, escaping through the perforations, is oxidized by coming in contact with the heated coke and the copper surface of the outer tube. The gases so produced pass into the condenser, which consists of a cylindrical tank—which may be of copper; it contains a copper pipe, through which circulates a refrigerating mixture capable of reducing the temperature in the tank to about 0°C ., at which temperature formic aldehyde condenses into a clear mobile liquid, which boils at -21°C ., and which polymerizes to paraformaldehyde at 20°C . After a certain process of purification, enough water is added to the formaldehyde so obtained to form a 40 per cent. solution; but this solution is not, strictly speaking, a solution of formaldehyde, as the pure formaldehyde polymerizes the moment the temperature rises above 20° and it is this property which renders the addition of water or alcohol necessary. Hence the aqueous solution of formaldehyde probably contains some paraformaldehyde. The commercial products are always aqueous solutions, the common strength being the 37 per cent. solution; a 50 per cent. solution is not permanent.

Properties.—Solution of formaldehyde or "Formaldehyde," as it is commonly called, is officially described as "a clear, colorless liquid, having a pungent odor and caustic taste; its vapor acts as an irritant upon the mucous membrane. Specific gravity: 1.075 to 1.078 at 25°C . (77°F). Miscible in all proportions with water and alcohol. On standing, Solution of Formaldehyde sometimes loses its transparency, the cloudiness being due to the separation of paraformaldehyde. If Solution of Formaldehyde be evaporated over sulphuric acid, or in a vacuum, white, solid, paraformaldehyde is rapidly formed, which is insoluble in water, and which, when heated to about 100°C . (212°F), sublimes, and between 153° and 172°C . (307.4° and 341.6°F) melts, gaseous formaldehyde being evolved. Solution of Formaldehyde should be neutral, or only faintly acid, to litmus paper. If 5 Cc. of Solution of Formaldehyde be diluted with 25 Cc. of distilled water, and 3 Cc. of silver am-

monium nitrate T.S. be added, a gray precipitate of finely divided metallic silver, which often adheres in part to the sides of the test-tube as a metallic mirror, will be produced. If to 5 Cc. of sulphuric acid in which a little salicylic acid has been dissolved, 2 drops of Solution of Formaldehyde be added and the liquid very gently warmed, a permanent deep red color should immediately appear. If 20 Cc. of Solution of Formaldehyde be evaporated to dryness on a water-bath, a white amorphous mass should remain, which, upon ignition, should not leave a residue (absence of *fixed impurities*). If 20 Cc. of Solution of Formaldehyde, to which 2 drops of phenolphthalein T.S. have been added, be titrated with normal potassium hydroxide V.S., not more than 0.5 Cc. of the latter should be required for neutralization (absence of more than 0.1 percent. of *formic and other acids*). If 20 Cc. of Solution of Formaldehyde be diluted with 60 Cc. of distilled water, and the liquid divided into four approximately equal portions, no turbidity or precipitate should be produced on the addition, severally, of silver nitrate T.S. (absence of *chloride*), barium chloride T.S. (absence of *sulphate*), hydrogen sulphide T.S. or potassium ferrocyanide T.S. (absence of *iron, lead, copper, etc.*), ammonium oxalate T.S. (absence of *calcium*).” *U. S.*

Formaldehyde may be determined in aqueous solutions by treatment with excess of standard ammonia, which converts it into hexamethylenamine. The excess of ammonia may then be titrated with standard acid. The mixture of the formaldehyde solution and ammonia should stand for at least twelve hours. This method, however, has not been found in practice to be as accurate as the hydrogen dioxide method, which was therefore chosen by the Revision Committee as the basis of the official assay process. (See below.) Because of the use of formaldehyde as a preservative of milk and food products the detection of small amounts of it is a matter of great importance. Several of the tests proposed are primarily applicable to milk only, being based on reactions which take place in the presence of milk proteids, so that if these tests are to be applied in testing other liquids for the presence of formaldehyde, the material must be mixed with an equal quantity of milk which has been shown previously to be free from formaldehyde. The principal tests may be divided into two groups, those in which a colored zone is obtained at the junction of two liquids, one of which has been superimposed upon the other, and those in which a color reaction is obtained in the body of the liquid tested. The first group includes the resorcinol-sulphuric acid test, the phenol-sulphuric acid test, and the sulphuric acid test of Hehner (carried out in the presence of milk). The method of application of the two tests first mentioned is as follows: To 5 Cc. of the liquid to be tested, one or two drops of a one per cent. aqueous solution of phenol

or resorcinol are added, and this liquid is then allowed to flow gently down the inside of the test tube containing 2 or 3 Cc. of the sulphuric acid so as to form a layer above the acid without mixing. In the presence of formaldehyde a rose-colored zone is produced in extreme dilution, or in more concentrated solutions an opaque pinkish zone above the rose-colored one. In the Hehner test, the liquid to be tested is mixed with an equal volume of formaldehyde-free milk, and this mixture is allowed to flow down the inside of the test tube upon 2 or 3 Cc. of commercial sulphuric acid containing a trace of ferric chloride. A violet zone is formed in the presence of formaldehyde. The general color tests constituting the second group of tests are the phenylhydrazine test with its modifications, the phloroglucinol test, the resorcinol-soda test, and the hydrochloric acid test. (A full discussion and comparison of these tests by C. H. LaWall will be found in *Am. Drug.*, 1905, vol. xlvii. p. 33.)

A. B. Lyons (*Proc. A. Ph. A.*, 1905, 326) proposes the use of *beef peptone* in place of milk (except when milk is under investigation) in Hehner's test (see above). He also suggests the use of morphine and sulphuric acid as a test for formaldehyde. (*Proc. A. Ph. A.*, 1905, 329.)

Assay. *U. S.* (8th Rev.).—“Transfer 3 Cc. of Solution of Formaldehyde to a well-stoppered Erlenmeyer flask, and weigh accurately. Add 50 Cc. of normal sodium hydroxide V.S., and follow this immediately, but slowly, through a small funnel, with 50 Cc. of solution of hydrogen dioxide, to which a drop of litmus T.S. has been added, and which has been neutralized with normal sodium hydroxide V.S. After the reaction has ceased and the foaming has subsided, rinse the funnel and sides of the vessel with distilled water, and, after allowing it to stand ten minutes, titrate back with normal sulphuric acid V.S., using litmus T.S. as indicator. Subtract the number of Cc. of normal sulphuric acid V.S. consumed, from 50 (the number of Cc. of normal sodium hydroxide V.S. employed), multiply the remainder by 2.979, and divide the product by the weight of the Solution taken; the quotient represents the percentage, by weight, of absolute Formaldehyde in the liquid.” *U. S.*

Uses.—In accordance with the discovery by Trillat in 1888, formaldehyde is a powerful germicide, ranking considerably below corrosive sublimate but above phenol. Various organisms can resist the influence of a one per cent. solution for three-quarters of an hour. When diffused through the air it should always be associated with an abundance of moisture, and it acts especially well when there is also a high temperature. It has a very powerful action on various forms of organic matter; one part in four thousand completely decolorizes wine, precipitating extractive and coloring matters. It does not, however, act

destructively upon books, clothing, or ordinary fabrics. Upon the higher animals its action is comparatively feeble, excepting as a violent irritant, producing when inhaled, even in an extremely diluted form, severe bronchitis or even pneumonia, and when taken internally a severe or fatal gastritis. As a poison it is more dangerous taken by the mouth than when exhibited hypodermically. Although an active coagulant of albumin in very dilute form, it so acts on albumin as to prevent its coagulation by heat. Its absorption is possible and the fact that the urine of animals to which it has been given is incapable of decomposition indicates that it is eliminated unchanged or more probably as formic acid. In human poisoning the symptoms have been those of a violent gastritis, and nephritis with stupor and coma in severe cases. It is alleged (Amdré, *A. J. P.*, 1900, 493) that ammonia or its acetates are antidotal to formaldehyde, forming hexamethylene tetramine.

Formaldehyde is never used in medicine except as a germicide, and as such is too irritant for use upon the body itself except under rare circumstances. When employed to disinfect such solid materials as may be soaked in it, the one per cent. solution should be used for 24 hours immersion. In disinfecting an apartment, windows, doors, chimneys, ventilators, and similar openings should be tightly closed, while the air should be made to contain at least one per cent. of formaldehyde gas, and at the end of twenty-four hours, when the apartment may be opened, should still be strongly impregnated. The gas may be obtained by the atomization of formalin or other solution of formaldehyde, but not by the simple evaporation of the solution, since the formaldehyde, upon the application of heat, becomes largely polymerized into a solid, *paraformaldehyde*, which gives off formaldehyde slowly and in small quantities. It is stated that the addition of glycerin to the solution of formaldehyde prevents the polymerization by heat of the formaldehyde, so that the so-called *glycoformalin* (formaldehyde thirty parts, water, sixty parts, glycerin ten parts) is preferable to the aqueous solution, although its use has the distinct disadvantage of leaving many articles in the room sticky from a coating of glycerin. The two per cent. solution of formaldehyde is very effective for the disinfecting of the hands of the surgeon, but has been found too irritating to be practical. A one to two per cent. solution is sometimes employed for the rendering of instruments aseptic, but its use is usually less convenient than that of a simple chamber in which by means of heated paraformaldehyde the instruments may be disinfected. It is stated that by the employment of this apparatus instruments contained in a chamber measuring one cubic foot may be absolutely disinfected in fifteen minutes by the evaporation of five grains of paraformaldehyde at a cost of one cent.

Formaldehyde is used for the preservation of human bodies; an injection of a one per cent. solution usually proves to be a sufficient quantity. The hardening of the tissues and the giving off of irritant vapors by the cadaver have however been found to be a great objection to its employment for purposes of this character.¹

LIQUOR HYDRARGYRI NITRATIS.

U. S. (Br.)

SOLUTION OF MERCURIC NITRATE

(*li'quor hÿ-drär'gy-rî nî-trä'tis*)

"A liquid, which should contain about 60 percent. of Mercuric Nitrate [$\text{Hg}(\text{NO}_2\text{O})_2 = 321.64$], and about 11 percent. of free nitric acid." U. S.

Liquor Hydrargyri Nitratis Acidus, Br.: Acid Solution of Mercuric Nitrate; Solution of Nitrate of Mercury; Solution of Pernitrate of Mercury; Liquor Hydrargyri Nitrici Oxydati; Azotate Mercurique liquide, *Fr. Cod.*; Deutazotate (Pernitrate) de Mercure liquide, *Fr.*; Mercurnitratlösung, Quecksilberoxydnitratlösung, Flüssiges Salpetersaures Quecksilberoxyd, *G.*

* "Red Mercuric Oxide, *forty grammes* [or 1 ounce av., 180 grains]; Nitric Acid, *forty-five grammes* [or 1 ounce av., 257 grains]; Distilled Water, *fifteen grammes* [or 231 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Mix the Nitric Acid with the Distilled Water, and dissolve the Red Mercuric Oxide in the mixture. Keep the product in glass-stoppered bottles." U. S.

"Mercury, 4 ounces (Imperial) or 120 grammes; Nitric Acid, 5 fl. ounces (Imp. meas.) or 150 cubic centimetres; Distilled Water, 1½ fl. ounces (Imp. meas.) or 45 cubic centimetres. Mix the Nitric Acid with the Distilled Water in a flask; dissolve the Mercury in the mixture without the application of heat; then boil gently for fifteen minutes; cool, and preserve the Solution, which should weigh about three times the quantity of the Mercury employed, in a stoppered bottle not exposed to the light." Br.

In the British process, mercury is dissolved, with the assistance of heat, in an excess of nitric acid, and there is formed an acid mercuric nitrate, which is brought to a determinate bulk by evaporation. The proportion of nitric

¹ *Kaiserling's solution* and method of using are as follows: Formaldehyde (40 per cent.), 750 Cc.; distilled water, 1000 Cc.; potassium nitrate, 10 Gm.; potassium acetate, 30 Gm. The heart, kidneys, and brain are kept during a period of twenty-four hours in Kaiserling's fluid, though no harm is done if they remain from thirty-six to forty-eight hours. The specimen is then transferred to alcohol of 80 per cent., where it should remain for not longer than twelve hours. Subsequently it is to be put in alcohol of 95 per cent. for two hours, and finally preserved in a mixture of equal parts of water and glycerin, to which thirty parts of potassium acetate have been added.

acid is sufficient not only to form mercuric nitrate, but also to furnish a large excess of acid.

Properties.—Solution of mercuric nitrate is "a clear, nearly colorless, heavy liquid, having a faint odor of nitric acid, and a strongly acid reaction. Specific gravity: about 2.086 at 25° C. (77° F.). On evaporating a few drops of the Solution in a porcelain dish, a white residue is left, which, on being heated, becomes successively yellow, red, and brown, and is finally completely volatilized. On a bright surface of copper, the Solution deposits a coating of metallic mercury. The Solution, diluted with water, yields with potassium hydroxide T.S. a yellow precipitate; and with potassium iodide T.S. a bright red one, soluble in an excess of the reagent. A clear crystal of ferrous sulphate dropped into the Solution rapidly acquires a brown color, and becomes surrounded by a brownish-black zone. No precipitation or cloudiness should occur in the Solution on the addition of water, or of diluted hydrochloric acid (absence of *mercurous salt*)." *U. S.* "A colorless and strongly acid liquid, which affords the reactions characteristic of mercuric salts and nitrates. It should not yield any characteristic reaction with the tests for mercurous salts. Specific gravity about 2.0." *Br.*

In the *U. S. P.* 1880 the definition stated that this solution contained about 50 per cent. of mercuric nitrate; in the *A. J. P.*, 1886, p. 577, F. X. Moerk affirmed that it did not afford a 50 per cent. solution, but a stronger one,—i.e., a 60 per cent. To make a 50 per cent. solution the following quantities should be used: Red Mercuric Oxide 33.32 parts; Nitric Acid 37.38 parts; Distilled Water sufficient to make 100 parts.

Mercuric nitrate, the salt present in this preparation, can be obtained in large crystals of the composition $\text{Hg}(\text{NO}_3)_2 + 4\text{H}_2\text{O}$, when its solution is allowed to evaporate slowly over sulphuric acid. The same salt, which is very deliquescent, is obtained as a crystalline magma by adding strong nitric acid to the concentrated solution.

Uses.—This preparation is much used as a caustic application to *cancers, lupus, ulcerations of the cervix, chancres*, etc. When a very free use is desired, it may be applied to the diseased surface by a camel's-hair brush, or preferably by a brush made of spun glass; usually, however, the application is made with a glass rod, or a match or similar fragment of wood. In *acne* and *boils*, a drop proportioned in size to the pustule applied to the apex is sometimes of service. The parts touched immediately become white, the surrounding parts inflame, and in a few days a yellow scab is formed, which gradually falls off. Sometimes the application produces salivation. When it is desirable to avoid this result, the cauterized part should be washed with water immediately after the application of the caustic. It is not used internally.

LIQUOR HYDRARGYRI PERCHLORIDI. Br.

SOLUTION OF MERCURIC CHLORIDE

(*li'quor hÿ-drär'gy-rî pÿr-çhlô'rî-dî*)

Liquor Hydrargyri Bichloridi: Solution of Bichloride of Mercury; Solution of Corrosive Sublimate; Sublimatlösung, *G.*

"Mercuric Chloride, 10 grains (Imperial) or 1 gramme; Distilled Water, 1 pint (Imp. meas.) or 875 cubic centimetres. Dissolve. This Solution contains 1-16 grain of Mercuric Chloride in 1 fluid drachm, or 0.114 gramme in 100 cubic centimetres." *Br.*

This solution may be used as affording a convenient method of exhibiting corrosive sublimate. The ammonium chloride formerly used (*Br. Ph.* 1885) to aid in dissolving the mercuric chloride has been omitted in the process of the *Br. Ph.* 1898.

Dose, from one-half to one fluidrachm (1.8 to 3.75 Cc.).

LIQUOR IODI COMPOSITUS. U. S. (Br.)

COMPOUND SOLUTION OF IODINE [Lugol's Solution]

(*li'quor î-ô'dî çom-pôs'î-tûs*)

"An aqueous solution, which should contain not less than 5 percent. of iodine and 10 percent. of potassium iodide." *U. S.*

Liquor Iodi Fortis, Br.: Strong Solution of Iodine; Liniment of Iodine, *Br.* 1885; *Liquor Iodinii Compositus, U. S.* 1870; *Soluté ioduré de Lugol, Fr.*; *Lugolische Jodlösung, G.*

* "Iodine, five grammes [or 77 grains]; Potassium Iodide, ten grammes [or 154 grains]; Distilled Water, a sufficient quantity, to make one hundred grammes [or 3 ounces av., 231 grains]. Dissolve the Iodine and Potassium Iodide in a sufficient quantity of Distilled Water to make the product weigh one hundred grammes [or 3 ounces av., 231 grains]. Keep the Solution in glass-stoppered bottles." *U. S.*

"Iodine, 1½ ounces (Imperial) or 50 grammes; Potassium Iodide, ¾ ounce (Imp.) or 30 grammes; Distilled Water, 1½ fl. ounces (Imp. meas.) or 50 cubic centimetres; Alcohol (90 per cent.), 9 fl. ounces (Imp. meas.) or 360 cubic centimetres. Dissolve the Potassium Iodide and the Iodine in the Distilled Water in a bottle; add the Alcohol and shake." *Br.*

In this solution iodine is dissolved in water with the assistance of potassium iodide. Iodine dissolves sparingly in water, but freely in a solution of this salt. In using potassium iodide to render iodine more soluble in water, the iodide is generally taken in a quantity twice the weight of the iodine, and this is the proportion adopted in the *U. S.* formula. The preparation is a concentrated solution of iodine with potassium iodide, and is intended to

facilitate the administration of the combination in drops. The present formula does not differ in strength from that of 1880. The specific gravity of the U. S. compound solution of iodine is 1.124 at 15° C. In the Br. Pharmacopœia a solution is directed having much more iodine than the U. S. solution, and weaker in potassium iodide, the former having about fifty grains of iodine and thirty grains of potassium iodide in the fluidounce, while the latter has nearly twenty-six grains of iodine and fifty-two grains of potassium iodide in the fluidounce, the difference in the fluidounce of the two Pharmacopœias being too small to enter into the calculation. The British solution is made with alcohol, and closely resembles the *Liniment of Iodine* of the Br. Ph. 1885. "For complete decolorization 6.3 Gm. of the Solution should require not less than 24.75 Cc. of tenth-normal sodium thiosulphate V.S. (each Cc. of the tenth-normal sodium thiosulphate V.S. corresponding to 0.2 percent. of Iodine)." U. S. The medicinal properties of the solution depend mainly on the free iodine contained in it.

Dose, of the U. S. P. solution, five minims (0.3 Cc.), containing about a quarter of a grain of iodine, three times a day, given in at least four tablespoonfuls of water or of milk, so as to avoid irritation of the stomach. The British solution, although not intended for internal administration, might be given in doses of two minims (0.12 Cc.).

LIQUOR KRAMERIEÆ CONCENTRATUS.

Br.

CONCENTRATED SOLUTION OF KRAMERIA

(L'quor kra-mě'ri-æ cōn-cēn-trā'tūs)

"Krameria Root, in No. 40 powder, 10 ounces (Imperial) or 500 grammes; Alcohol (20 per cent.), 25 fl. ounces (Imp. meas.) or 1250 cubic centimetres or a sufficient quantity. Moisten the Krameria with five fluid ounces (Imp. meas.) or two hundred and fifty cubic centimetres of the Alcohol; pack in a closed percolator; set aside for three days; percolate with the remaining Alcohol, added in ten equal portions at intervals of twelve hours; continue percolation with more Alcohol until the product measures one pint (Imp. meas.) or one thousand cubic centimetres." Br.

This concentrated solution of the Br. Ph. 1898 is really a 50 per cent. fluidextract, or a half strength official fluidextract. It belongs to the class of "liquors" introduced for the purpose of diluting with water to make infusions. (See *Infusum Kramerie*, p. 655.) F. C. J. Bird has shown that the keeping properties of this preparation, which under the official conditions are very unsatisfactory, can be improved by the addition of about 5 per cent. of alcohol, or, better still, by adding 10 per cent. of glycerin. A preparation containing

one-tenth its volume of glycerin remained bright, without deposit, when slightly acidified with acetic acid and allowed to stand for a few days, or when kept under ordinary conditions for some months, and also remained clear, without formation of any precipitate, when exposed to a temperature of about 0° C. Under similar conditions the official preparation yielded copious precipitates, while that containing 5 per cent. more alcohol also became turbid and gave a deposit, though in a lesser degree. Moreover, the preparation containing glycerin was rendered less turbid than the others on dilution with water, while its taste was somewhat more agreeable and its astringency practically the same. (*Y. B. P.*, 1902, 461-465.) This preparation fully represents the crude drug, and may be used internally.

Dose, from one-half to one fluidrachm (1.8 to 3.75 Cc.).

LIQUOR MAGNESII CARBONATIS. Br.

SOLUTION OF MAGNESIUM CARBONATE

[Fluid Magnesia]

(L'quor mǎg-ně'si-i cār-bō-nā'tis)

Eau magnésienne, Magnésie liquide, *Fr.*; Kohlen-saure Magnesialösung, Magnesiawasser, *G.*

"Magnesium Sulphate, 2 ounces (Imperial) or 40 grammes; Sodium Carbonate, 2½ ounces (Imp.) or 50 grammes; Distilled Water, a sufficient quantity. Dissolve the two salts separately, each in half a pint (Imp. meas.) or two hundred cubic centimetres of the Distilled Water; heat the solution of Magnesium Sulphate to the boiling point; add to it the solution of Sodium Carbonate; boil them together until carbonic anhydride ceases to be evolved; collect the precipitated magnesium carbonate on a calico filter; wash it with Distilled Water until the filtrate is free from sulphate. Mix the washed precipitate with a pint (Imp. meas.) or four hundred cubic centimetres of Distilled Water; place the mixture in a suitable apparatus; force into it pure washed carbonic anhydride; let the mixture remain in contact with excess of carbonic anhydride, retained under a pressure of about three atmospheres, for twenty-four hours or longer; decant the Solution, into which again pass carbonic anhydride. Keep the Solution in bottles of convenient sizes, securely closed to prevent the escape of carbonic anhydride." Br.

The object of this process is to obtain a solution of magnesium carbonate by means of carbon dioxide, the carbonate being insoluble in pure water. The first step is to prepare a freshly precipitated hydrated magnesium carbonate, which is more readily dissolved than is a carbonate which has been kept for some time. As the magnesium carbonate of the Br. Pharmacopœia consists of three molecules of the neutral carbonate and one of magnesium hydroxide with four molecules of water, it follows that, in its preparation from the two

salts used in the process, a portion of carbon dioxide escapes, and the boiling is directed to be continued until the escape of the gas ceases, so that the normal composition may be insured, and a longer heat, which might affect the constitution of the carbonate so as to diminish its solubility, avoided. The precipitate is thoroughly washed, in order to remove every trace of sodium sulphate, which may be indicated by the non-action of the test of barium chloride. The next step is to dissolve the precipitated carbonate in water impregnated with carbon dioxide, and, as the solution even thus favored is slowly effected, the carbonate is directed to remain exposed to the action of carbon dioxide, under pressure, for twenty-four hours, and still the whole of the carbonate is not dissolved, and filtration is necessary. According to the Br. Pharm. the solution "effervesces slightly, or not at all, when the containing vessel is first opened. It should yield no characteristic reaction with the test for sulphates. 20 cubic centimetres evaporated to dryness afford a white residue of pure hydrous magnesium carbonate, which after being calcined weighs between 0.16 and 0.19 gramme. This residue is insoluble in water, and when dissolved in dilute acid responds to the tests for magnesium. This Solution contains nearly 10 grains of the official Magnesium Carbonate in 1 fluid ounce, or about 2 grammes in 100 cubic centimetres." *Br.* On exposure to the air, some of the carbon dioxide escapes, and a portion of the salt is deposited. Redwood proposes to remedy this by reducing the strength of the solution. (*P. J.*, 2d ser., xi. 397.) Indeed, it has been shown by C. Muncy that the preparation as it occurs in commerce is usually much below the standard strength.

This solution is but slightly effervescent, is clear, and should be free from bitterness. Nevertheless its taste is more disagreeable than is that of the undissolved carbonate, over which it has no advantage.

Dose, as an antacid laxative, from one to two fluidounces (30 to 60 Cc.).

LIQUOR MAGNESII CITRATIS. U. S.

SOLUTION OF MAGNESIUM CITRATE

(lí'quor mǎg-ně'si-I cĭ-trā'tis)

Liquor Magnesii Citrici; Solution of Citrate of Magnesium; Limonade purgative au Citrate de Magnésie. *Fr. Cod.*; Flüssige Citronensaure Magnesia, Magnesiumcitratlösung, Magnesiumlimonade, *G.*; Limonata magnesiacă, *It.*; Limonada purgante de citrato magnesico, *Sp.*

* "Magnesium Carbonate, fifteen grammes [or 231 grains]; Citric Acid, thirty-three grammes [or 1 ounce av., 72 grains]; Syrup of Citric Acid, sixty cubic centimeters [or 2 fluidounces, 14 minims]; Potassium Bicarbonate, two and one-half grammes [or 39 grains]; Water, a sufficient quantity. Dissolve the Citric Acid in one hundred and twenty cubic centimeters [or 4 fluidounces, 28 minims] of

Water, and, having added the Magnesium Carbonate, stir until it is dissolved. Filter the solution into a strong bottle of the capacity of about three hundred and sixty cubic centimeters [or 12 fluidounces, 83 minims], containing the Syrup of Citric Acid. Then add enough Water to nearly fill the bottle, drop in the Potassium Bicarbonate, and immediately stopper the bottle securely. Lastly, shake the mixture occasionally, until the Potassium Bicarbonate is dissolved. This solution should be freshly prepared when wanted." *U. S.*

This formula first appeared in the second edition of the *U. S. Pharmacopœia* of 1850. The original formula was soon found to have defects. Four-fifths of the carbonate was dissolved in the citric acid, and the solution filtered into a bottle containing the syrup of citric acid, and then the reserved fifth, mixed with water, was added to the acid citrate, and the bottle tightly corked. The addition of the reserved carbonate was intended to impregnate the preparation with carbon dioxide by its solution in the excess of citric acid. To effect the solution of this reserved carbonate required at least half an hour. But the chief objection to the formula as originally framed was that the magnesium citrate, when the solution was kept for some days, crystallized out in the form of a white granular precipitate, which rendered the solution unfit for medicinal use. This precipitate was found by Procter to be $Mg_3(C_6H_5O_7)_2 + 14H_2O$. This still occurs to some extent, although more slowly, and probably cannot be avoided except by a very great reduction in the amount of magnesia.¹ The *U. S. P.* (8th Rev.) process improved the formula by increasing the quantity of citric acid, using 33 Gm. instead of 30 Gm. formerly used. The use of potassium bicarbonate introduces potassium citrate, but in too small a proportion to be of any consequence. It is somewhat more convenient to use calcined magnesia in place of the carbonate, and in one of the best processes that we have seen the fifteen grammes of carbonate in the official formula are replaced by five grammes of Jennings's light calcined

¹ *Interimpropaneous Liquor Magnesii Citratiss.*—The following formula has been proposed by J. C. Wharton as a means of always giving a customer a fresh solution of the citrate, which is substantially the same as that of the *U. S. Pharmacopœia*. "Syrup No. 1. Take of simple Syrup two pints; Spirit of Lemon sixty-four minims; Potassium Bicarbonate six hundred and forty grains. Mix, and make solution, and keep ready for use. Syrup No. 2. Take of Calcined Magnesia eighty-eight grains; Citric Acid four hundred and eight grains; Distilled Water a sufficient quantity. Mix the Magnesia and Citric Acid in a mortar and add one and a half fluidounces of Water. Stir with a pestle, and break up the lumps of acid if there be any. After solution is effected, add sufficient Water to make up the amount of one bottle nearly full, when mixed with two fluidounces of Syrup No. 1. These two solutions are to be kept separately. When Solution of Magnesium Citrate is called for, pour into the bottle Syrup No. 1 first, without touching the mouth or sides of the bottle; then pour in along the sides of the bottle Syrup No. 2, so as to avoid as far as possible mixing them, cork and agitate." For Edell's process, see *Proc. A. Ph.*, 1894, 582; Widlum's process, *Proc. A. Ph.*, 1896, 428.

magnesia. We prefer a modification in the manipulation of the official process; if instead of the solution being filtered into the bottles containing the syrup it is filtered into a separate vessel, and then the proper quantity poured very carefully down the inside of the bottle, or with the aid of a funnel having only a lateral opening so that the liquid is delivered against the sides of the bottle, so as not to disturb the heavy layer of syrup, if then the crystals of bicarbonate be dropped in, very little loss of carbon dioxide will ensue if the bottle is at once securely stoppered. When the bottle is dispensed, a vigorous shake at once liberates the carbon dioxide, and the patient is sure to have a highly effervescent liquid. Special bottles for this solution can now be procured which have a "patent stopper" attached; they are very convenient. Solid magnesium citrate is best used in the form of the effervescent magnesium citrate of the U. S. P. 1890.¹

¹ *Magnesii Citras Effervescens*. U. S. 1890. *Effervescent Magnesium Citrate*. *Magnesii Citras Granulatus*, U. S. 1880; *Granulated Citrate of Magnesium*. "Magnesium Carbonate, ten grammes [or 154 grains]; Citric Acid, forty-six grammes [or 1 ounce av., 272 grains]; Sodium Bicarbonate, thirty-four grammes [or 1 ounce av., 87 grains]; Sugar, in fine powder, eight grammes [or 123 grains]; Alcohol, Distilled Water, each, a sufficient quantity. Mix the Magnesium Carbonate intimately with thirty grammes [or 1 ounce av., 25 grains] of Citric Acid and four cubic centimeters [or 65 minims] of Distilled Water, so as to form a thick paste. Dry this at a temperature not exceeding 30° C. (86° F.), and reduce it to a fine powder. Then mix it intimately with the sugar, the Sodium Bicarbonate, and the remainder of the Citric Acid previously reduced to a very fine powder. Dampen the powder with a sufficient quantity of Alcohol, so as to form a mass, and rub it through a No. 6 tinned-iron sieve. Then dry it, and reduce it to a coarse, granular powder. Keep the product in well-closed vessels." U. S. 1890. This was an official salt, intended to furnish an agreeable, effervescent drink. It is very important to obey the direction to keep it in well-closed bottles, for if access of air be permitted the moisture would soon cause the acid to act upon the carbonates and liberate the carbon dioxide gas gradually, and thus destroy the effervescent character of the preparation, its principal recommendation. Large quantities of so-called effervescent magnesium citrate are sold in this country and in England which contain no magnesium citrate at all, being effervescent salts of sodium tartrate. W. L. Scoville analyzed three commercial specimens. (*Ph. Rec.*, 1892, 267.) One English brand contained anhydrous magnesium sulphate, Rochelle salt, sodium bicarbonate, tartaric acid, and sugar; another English salt contained magnesium sulphate, sodium sulphate, potassium carbonate, sodium bicarbonate, tartaric acid, and sugar; a Philadelphia preparation contained magnesium carbonate, citric and tartaric acids, sodium and potassium bicarbonates, and sugar. It is in the form of "a white, coarsely granular salt, without odor, and having a mildly acidulous, refreshing taste. Deliquescent on exposure to the air. Soluble, with copious effervescence, in 2 parts of water at 15° C. (59° F.), and very soluble in boiling water; almost insoluble in alcohol. The aqueous solution (1 in 20) has an acid reaction, and, after the addition of ammonium chloride test-solution and a slight excess of ammonia water, it yields, with sodium phosphate test-solution, a white, crystalline precipitate. If to another portion of the aqueous solution a little calcium chloride test-solution be added and then a slight excess of ammonia water, the filtered liquid will deposit a white precipitate on boiling. A saturated aqueous solution of the salt, when mixed with potassium acetate test-solution and a small quantity of acetic acid, should not yield a white, crystalline precipitate (absence of tartrate)." U. S. 1890. The medicinal properties are those of its solution, except that, as it does not contain a large excess of acid, it is less pleasant to the palate,

Properties.—This official solution is founded on a preparation proposed by Roge Delabarre, and improved by Rabourdin of Paris. It is an aqueous solution of magnesium citrate, containing an excess of citric acid, impregnated with carbon dioxide and sweetened with syrup. When properly prepared, it is a clear liquid, having an agreeable taste like that of lemonade. Overlooking the excess of acid which it contains, the salt present is the tribasic citrate, in which the six atoms of hydrogen from two molecules of citric acid are replaced by three atoms of magnesium. Accordingly, it consists of two molecules of citric acid and three atoms of magnesium. It is advisable in preparing the solution to introduce the magnesia in small portions, for if too hastily added it is liable to cause the formation of the neutral citrate, which cannot afterwards be readily dissolved. (*A. J. P.*, 1867.) Dorvault makes a solid magnesium citrate which is perfectly and readily soluble, by melting on a sand bath 100 parts of crystallized citric acid in its water of crystallization, and thoroughly incorporating with it 29 parts of calcined magnesia. A pasty mixture is formed, which soon hardens, and may be pulverized for use. Magnesium citrate, thus prepared, is soluble in twice its weight of water. When in saturated solution it soon precipitates as a nearly insoluble hydroxide, but with eight or ten times its weight of water it forms a permanent solution. Simonin finds that an insoluble magnesium citrate may be restored to solubility in boiling water by being thoroughly rubbed up with water so as to form a paste. The necessary trituration will be abridged if a little citric acid be added. (*Ann. Ther.*, 1857.)²

but may in some cases suit the stomach better. (See *Liquor Magnesii Citratis*.) It has also the advantages of portability. The dose is from one to three teaspoonfuls.

² *Solid Magnesium Citrate*.—This salt as heretofore prepared, though soluble at first, is apt to become more or less insoluble when kept, in consequence of molecular change. The following process, by de Letter, of Brussels, yields a salt which is said to retain its solubility indefinitely. "Take of Citric Acid 20 parts, and of Magnesium Carbonate 12 parts. Powder the acid finely, and mix it intimately with the carbonate, also in fine powder. Allow the mixture to stand, at the ordinary temperature, for four or five days, or until it ceases to manifest reaction, when a little is thrown into water. During this time the powder slowly swells up, and gradually assumes the appearance of a spongy mass. Dry this at 30° C. (86° F.), pulverize it, and keep the powder in closely-stoppered vials." According to de Letter, water, in a certain quantity, favors the formation of an insoluble hydroxide, and hence the success of his process, in which no other water is present than that which is solidified in the dry materials. (*A. J. P.*, 1863, p. 312.) Hager has been unable to prepare a soluble salt by the process of de Letter. He considers magnesium citrate as presenting itself in three forms: 1, *crystallizable*, soluble in from 80 to 90 parts of water, with the formula $Mg_2(C_6H_5O_7)_2 + 7H_2O$; 2, *amorphous*, soluble in 8 or 10 parts of water, with a strong tendency to crystallize. It is the crystalline variety, presenting the form of microscopic needles, that occasions the difficulty, and its production should be avoided. Hager proceeds in the following manner. Rub 40 parts of citric acid and 25 of magnesium carbonate, both in powder, with sufficient alcohol of 0.833 to make a thick mixture, and, having allowed this to stand for several days, at a medium temperature, dry it at a heat of 45°

For other modifications, suggestions, etc., see Kondratowisch, *N. R.*, 1883, p. 246; Neynaber, *A. J. P.*, 1884, p. 472 (the proposed substitution of acetic acid by the latter is not desirable, because of the impossibility of avoiding an empyreumatic taste); also A. B. Stevens, *Proc. Mich. State Pharm. Assoc.*, 1885; and F. W. Sennewald, *Nat. Drug.*, 1887.

Magnesium metatartrate has been proposed, in the place of the citrate, by Léger, who, however, states that as a purgative it is more powerful than the citrate, resembling the sulphate. On account of its pleasant taste it might, perhaps, be substituted for Epsom salt. Léger prepares *metatartaric acid* in the following manner. Into a porcelain dish put a small amount of tartaric acid, and heat it, with occasional agitation, on a slow fire until it fuses; then add successively small portions of the acid, so as not to cool the mass, lest it solidify and burn. When the dish is two-thirds full, cease adding the acid, but continue the heat until the mass, at first puffed up and doughy, is completely melted into an amber-colored liquid. Withdraw it from the fire, and when sufficiently cooled form it into pebbles, which must be kept in closely-stoppered bottles on account of their being hygroscopic. This acid is very soluble in water, and in this state greedily attacks the magnesium carbonate, forming with it a salt which is permanent even when in solution. (*J. P. C.*, xix. 226.)

Uses.—This solution is a cooling cathartic, and operates mildly. It has come into extensive use in the United States, on account of the facility with which it may be taken and its acceptability to the stomach.

Dose, as a purge, the whole quantity directed in the formula, or twelve fluidounces (360 Cc.); as a laxative, half that quantity.

LIQUOR MORPHINÆ ACETATIS. Br.

SOLUTION OF MORPHINE ACETATE

(lí'quor mör-phí'næ äç-ç-tä'tis)

Soluté d'Acétate de Morphine, *Fr.*; Essigsäure Morphinlösung, *G.*

"Morphine Acetate, 17½ grains (Imperial) or 1 gramme; Diluted Acetic Acid, 38 minims (Imp. meas.) or 2 cubic centimetres; Alcohol (90 per cent.), 1 fl. ounce (Imp. meas.) or 25 cubic centimetres; Distilled Water, a sufficient quantity. Mix the Alcohol with an equal volume of Distilled Water, adding the Diluted Acetic Acid; dissolve the Morphine Acetate in the mixture; dilute with sufficient Distilled Water to produce four fluid ounces (Imp. meas.) or one hundred cubic centimetres of the

Solution of Morphine Acetate. 110 minims contain 1 grain of Morphine Acetate; 100 cubic centimetres contain 1 gramme." *Br.*

Morphine Acetate often contains a little uncombined morphine, in consequence of the escape of a portion of the acid during its evaporation, and especially when this is pushed to dryness. It is on this account apt to be unreliable. Hence the addition of the diluted acetic acid, which at the same time neutralizes the alkaloid in excess and enables the solution to be completely effected. The alcohol is added as a preservative. The present solution contains about 1 per cent. of morphine acetate.

Dose, from fifteen to thirty minims (0.9 to 1.8 Cc.), equivalent to from one-eighth to one-fourth of a grain of the morphine acetate, and to about as many drops of tincture of opium as minims of the solution.

LIQUOR MORPHINÆ HYDRO-CHLORIDI. Br.

SOLUTION OF MORPHINE HYDROCHLORIDE

(lí'quor mör-phí'næ hí-drö-çhlö'ri-di)

Solution of Hydrochlorate of Morphine, *Br.* 1885; Liquor Morphine Muriatis, *Dub.*; Solution of Muriate of Morphine; Soluté de Hydrochlorate de Morphine, *Fr.*; Salzsäure Morphinlösung, *G.*

"Morphine Hydrochloride, 17½ grains (Imperial) or 1 gramme; Diluted Hydrochloric Acid, 38 minims (Imp. meas.) or two cubic centimetres; Alcohol (90 per cent.), 1 fl. ounce (Imp. meas.) or 25 cubic centimetres; Distilled Water, a sufficient quantity. Mix the Alcohol with an equal volume of Distilled Water, adding the Diluted Hydrochloric Acid; dissolve the Morphine Hydrochloride in the mixture; dilute with sufficient Distilled Water to produce four fluid ounces (Imp. meas.) or one hundred cubic centimetres of the Solution of Morphine Hydrochloride. 110 minims contain 1 grain of Morphine Hydrochloride; 100 cubic centimetres contain 1 gramme." *Br.*

The use of the alcohol is to prevent spontaneous decomposition, that of the acid probably to assist in the solution of the salt. The solution contains about 1 per cent. of morphine hydrochloride.

Dose, from fifteen to thirty minims (0.9 to 1.8 Cc.).

LIQUOR MORPHINÆ TARTRATIS. Br.

SOLUTION OF MORPHINE TARTRATE

(lí'quor mör-phí'næ tär-trä'tis)

Soluté de Tartrate de Morphine, *Fr.*; Weinstein-säure Morphinlösung, *G.*

"Morphine Tartrate, 17½ grains (Imperial) or 1 gramme; Alcohol (90 per cent.), 1 fl. ounce (Imp. meas.) or 25 cubic centimetres; Distilled Water, a sufficient quantity. Mix the Alcohol with an equal volume of Distilled Water; dis-

C. (113° F.). The product is the amorphous salt, soluble in 2.5 parts of water, in half an hour at 15.5° C. (60° F.), immediately at 30° C. (86° F.). Its solution, whether made with hot or cold water, retains its clearness after long standing. The salt is neutral, and contains about 13 mols. of water. To succeed certainly it is necessary that the magnesium carbonate be free from dust and impurities. (*A. J. P.*, 1864, p. 19.)

solve the Morphine Tartrate in the mixture; add sufficient Distilled Water to produce *four fluid ounces* (Imp. meas.) or one hundred cubic centimetres of the Solution." Br.

This solution was introduced into the Br. Ph. 1898 because of the superior solubility and stability of the morphine tartrate, and its adaptability for hypodermic administration, alcohol being used to preserve the liquid. It is of the same strength as the other solutions of morphine, about 1 per cent. "110 minims contain 1 grain of Morphine Tartrate; 100 cubic centimetres contain 1 gramme." Br.

Dose, from fifteen to thirty minims (0.9 to 1.8 Cc.).¹

LIQUOR PANCREATIS. Br.

PANCREATIC SOLUTION

(lí'quor pân-crê'a-tis)

"A liquid preparation containing the digestive principles of the fresh pancreas of the pig. The preparation is most active when the animal from which it is obtained has been fed shortly before being killed. *Five ounces* (Imperial) or two hundred and fifty grammes of the pancreas, freed from fat and external membrane and finely divided by trituration with washed sand or powdered pumice stone, should be digested, in a closed vessel, in *twenty fluid ounces* (Imp. meas.) or one thousand cubic centimetres of Alcohol (20 per cent.) for seven days, and then filtered." Br.

Liquor Pancreaticus; Soluté de Pancréatine, Fr.; Pankreatinlösung, Pankreasessenz, G.

This official preparation of the Br. Ph. 1898 has been introduced to supply the demand for a liquid digestive solution made from the pancreas; it closely resembles the preparation recommended by Benger. (*Proc. Roy. Soc.*, xxxii. 145; see also *Pankreatinum*.) The test, modelled on the U. S. P. test for pancreatin, is as follows: "If 2 cubic centimetres of the Solution, together with 0.2 gramme of sodium bicarbonate and 20 cubic centimetres of water, be added to 80 cubic centimetres of milk, and the mixture be kept at a temperature of 113° F. (45° C.) for one hour, coagulation should no longer occur on the addition of *nitric acid*." Br. The solution digests albuminoids, converts starch into sugar in an alkaline solution, albumin and fibrin into peptones, and peptonizes milk. As it acts normally in alkaline solutions, while the gastric juices are strongly acid, its practical value as an internal medicament is doubtful.

Dose, from one to two fluidrachms (3.75 to 7.5 Cc.).

¹ Various solutions of morphine sulphate have been in vogue, but have been abandoned by the Pharmacopœias on account of their tendency to undergo decomposition. The U. S. 1870 solution (*Liquor Morphia Sulphatis*) contained 1 grain of morphine sulphate to the fluidounce; the Br. 1885 solution 4.375 grains in the same quantity. *Magendie's solution of Morphine* was of the strength of 18 grains to the fluidounce.

LIQUOR PICIS CARBONIS. Br.

SOLUTION OF COAL TAR

(lí'quor pí'cis cār-bō'nīs)

Soluté de Goudron de Houille, Fr.; Kohlentheerlösung, G.

"Prepared Coal Tar, 4 ounces (Imperial) or 200 grammes; Quillaia Bark, in No. 20 powder, 2 ounces (Imp.) or 100 grammes; Alcohol (90 per cent.), a sufficient quantity. Moisten the powdered Quillaia Bark with one fluid ounce (Imp. meas.) or fifty cubic centimetres of the Alcohol, and complete the percolation process with the remainder of the Alcohol as for Tinctures, one pint (Imp. meas.) or one thousand cubic centimetres being produced. To the resulting percolate add the Prepared Coal Tar, and digest the mixture at 120° F. (48.9° C.) for two days, occasionally stirring. Cool and decant, or filter." Br.

This solution of the Br. Ph. 1898 is practically identical with *Liquor Carbonis Detergens*, *Coal Tar Saponine*, and similar well known preparations which have been largely used by dermatologists. The process for solution of coal tar is modelled after that for compound tincture of coal tar, proposed by L. A. Duhring (*Am. J. M. S.*), who recommended digesting 1 part of coal tar with 6 parts of tincture of quillaia for eight days, and then filtering. It owes its virtues largely to phenol and other derivatives of coal tar. (See *Coal Tar*, PART II.)

Solution of coal tar is stimulating, and is prescribed, diluted with from ten to fifty parts of water, as a wash in *eczema*, *psoriasis*, *pruritis*, and other skin diseases.

LIQUOR PLUMBI SUBACETATIS.

U. S. (Br.)

SOLUTION OF LEAD SUBACETATE

[Goulard's Extract]

(lí'quor plūm'bī sūb-āc-ē-tā'tīs)

"An aqueous liquid, which should contain in solution not less than 25 percent. of Lead Subacetate [approximately $\text{Pb}_2\text{O}(\text{CH}_3\text{COO})_2 = 543.74$]." U. S.

Liquor Plumbi Subacetatis Fortis, Br., Strong Solution of Lead Subacetate; Acetum Plumbi, Acetum Saturni, Plumbum Hydrico-Aceticum Solutum; Acétate (sous-) de Plomb liquide, Fr. Cod.; Extrait de Goulard, Vinaigre de Plomb (de Saturne), Fr.; Liquor Plumbi Subacetici, P. G.; Bleiessig, G.

* "Lead Acetate, one hundred and eighty grammes [or 6 ounces av., 153 grains]; Lead Oxide, one hundred and ten grammes [or 3 ounces av., 385 grains]; Distilled Water, a sufficient quantity, to make one thousand grammes [or 35 ounces av., 120 grains]. To the finely powdered Lead Oxide contained in a porcelain dish, of about one liter [or 2 pints] capacity, add slowly and in portions, with constant stirring, the Lead Acetate which has

been previously dissolved in *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims] of boiling Distilled Water, and boil the liquid for half an hour, with occasional stirring. Finally, when cool, filter the Solution, and add sufficient Distilled Water, which has been previously boiled and cooled, to make the finished product weigh *one thousand grammes* [or 35 ounces av., 120 grains]. Keep the Solution in well-stoppered bottles." *U. S.*

"Lead Acetate, 5 ounces (Imperial) or 250 grammes; Lead Oxide, in powder, 3½ ounces (Imp.) or 175 grammes; Distilled Water, a sufficient quantity. Boil the Lead Acetate and the Lead Oxide in *one pint* (Imp. meas.) or one thousand cubic centimetres of Distilled Water for half an hour, constantly stirring, and maintaining the volume of the liquid by occasional additions of Distilled Water; filter; when the liquid is cold add sufficient Distilled Water to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Strong Solution." *Br.* The sp. gr. of the solution is 1.275.

The *U. S.* (8th Rev.) process does not differ essentially from that formerly official, the quantities of both lead ingredients were, however, slightly increased. Crystallized lead acetate consists of one atom of lead 205.35, two acetic acid groups 117.16, and three molecules of water 53.64 = 376.15. The formula is $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2 + 3\text{H}_2\text{O}$. Litharge, as usually found in commerce, is an impure lead oxide. When solution of lead acetate is boiled with lead oxide, a large quantity of the oxide is dissolved, and a lead subacetate is formed which remains in solution. The precise composition of the subacetate varies with the proportion of lead acetate and of litharge employed. Thus, starting with three molecules of normal acetate, $\text{Pb}_3(\text{C}_2\text{H}_3\text{O}_2)_6$, we may have $\text{Pb}_3\text{O}(\text{C}_2\text{H}_3\text{O}_2)_4$ and $\text{Pb}_3\text{O}_2(\text{C}_2\text{H}_3\text{O}_2)_2$ formed successively. The latter of these oxyacetates is known as Goulard's, and a mixture of the two constitutes the basis of the official solution. In executing the process, the litharge should be employed in very fine powder, and, according to Thénard, should be previously calcined in order to decompose the lead carbonate which it always contains in greater or less proportion, and which is not dissolved by the solution of the acetate. Nevning states that a solution of lead subacetate more permanent than the official one may be prepared by simply allowing litharge to remain for twenty-four hours in a solution of lead acetate, with occasional agitation. This preparation probably contains much less of the lead oxide than does the official solution. Courtonne recommends dissolving seventy-five parts by weight of crystallized lead acetate in one hundred and sixty-five parts of water, and adding eleven parts of ammonia water, sp. gr. 0.923. This quick method has the disadvantage of containing ammonium acetate in small quantity. (*Chem. Ztg.*, 1894.) For Haussmann's method by agitating the lead

salts with hot water, see *A. J. P.*, 1897, 559; *A. J. P.*, 1896, 427; *M. R.*, 1896, 329; *Ph. Rev.*, 1896, 250.

Properties.—The solution of lead subacetate of the *U. S. Pharmacopœia* is "a clear, colorless liquid, odorless, having a sweetish, astringent taste, and an alkaline reaction. On exposure to the air it absorbs carbon dioxide, which causes the formation of a white precipitate. Specific gravity: about 1.235 at 25° C. (77° F.). When Solution of Lead Subacetate is added to a solution of acacia, it produces a dense, white precipitate (distinction from normal lead acetate). In other respects the Solution conforms to the reactions and tests for an aqueous solution of lead acetate given under *Plumbi Acetas*. If 10 Gm. of the Solution be diluted with distilled water, which has been previously boiled and cooled, to measure 100 Cc., and 13.6 (13.594) Cc. of this be added to 35 Cc. of tenth-normal oxalic acid V.S., contained in a graduated cylinder, and, after thoroughly shaking, the mixture be diluted with distilled water to measure 50 Cc., and again well shaken, then, after the precipitate has settled, 10 Cc. of the clear solution, after diluting with about 50 Cc. of water and adding 5 Cc. of sulphuric acid, should require not more than 2 Cc. of tenth-normal potassium permanganate V.S. to produce a permanent pink tint (each Cc. of tenth-normal oxalic acid V.S. required for the precipitation of the 13.6 Cc. of the diluted Solution, corresponding to 1 percent. of Lead Subacetate)." *U. S.* "A clear colorless liquid, with alkaline reaction and sweet astringent taste. It becomes turbid by exposure to the air. It forms with *mucilage of gum acacia* an opaque white jelly. It affords the reactions characteristic of lead and of acetates. Specific gravity 1.275. Each gramme should require for complete precipitation 17 cubic centimetres of the *decinormal volumetric solution of sulphuric acid*." *Br.* When concentrated by evaporation, it deposits on cooling crystalline plates, which, according to Barker are flat, rhomboidal prisms, with dihedral summits.¹ It has an alkaline reaction, tingeing the syrup of violets green, and reddening turmeric paper. One of its most striking properties is the extreme facility with which it is decomposed. Carbon dioxide throws down a white precipitate of lead carbonate; and this happens by mere exposure to the air, or by mixture even with distilled water, if this has had an opportunity of absorbing carbon dioxide from the atmosphere. It affords precipitates also with the alkalies, alkaline earths, and their carbonates, with sulphuric

¹ *Crystallized Lead Subacetate.*—Jeannel prepares crystallized lead subacetate in accordance with the following formula. Triturate six parts of neutral lead acetate with two parts of pure litharge, and add one part of water. Heat in a porcelain dish, stirring with a glass rod, until fusion and finally ebullition occur. After two or three minutes of boiling, filter through paper in a funnel heated by a sand bath. Allow to cool and crystallize. (*J. P. C.*, 4e sér., xl. 54.)

and hydrochloric acids free or combined, with hydrogen sulphide and the sulphhydrates, with the soluble iodides and chlorides, and, according to Thénard, with solutions of nearly all neutral salts. Solutions of gum, tannin, most vegetable coloring principles, and many animal substances, particularly albumin, produce with it precipitates consisting of the substance added and lead oxide. It should be kept in well-stoppered bottles. It is known to contain a salt of acetic acid by emitting an acetous odor when treated with sulphuric acid, and a salt of lead by yielding a white precipitate with an alkaline carbonate, a yellow one with potassium iodide, and a black one with hydrogen sulphide. It is distinguished from the solution of lead acetate by being precipitated by gum arabic. For a method (other than the official) of assaying this solution volumetrically, see *P. J.*, 1886, 656.

Uses.—This solution is astringent and sedative, but is employed only as an external application. It is highly useful in inflammation arising from *sprains, bruises, burns, blisters*, etc., to which it is applied by means of linen cloths, which should be removed as fast as they become dry. It always, however, requires to be diluted. From four fluidrachms to a fluidounce (15 to 30 Cc.), added to a pint (480 Cc.) of distilled water, forms a solution sufficiently strong in ordinary cases of external inflammation. When applied to the skin denuded of the cuticle, the solution should be still weaker, as constitutional effects might result from the absorption of the lead. Paralysis is said to have been produced by its local action; and poisoning by its injection for gonorrhœa has been reported. (*Dublin Journ. Med. Sci.*, 1874.) The solution has the common name of *Goulard's extract*, derived from a surgeon of Montpellier by whom it was introduced into general notice, though previously employed.

Off. Prep.—Ceratum Plumbi Subacetatis, *U. S.*; Liquor Plumbi Subacetatis Dilutus, *U. S.*, *Br.*

LIQUOR PLUMBI SUBACETATIS DILUTUS. *U. S.*, *Br.*

DILUTED SOLUTION OF LEAD SUBACETATE [Lead Water]

(lī'quor plūm'bī sūb-āc-ē-tā'tis dī-lū'tūs)

"An aqueous liquid, which should contain about 1 percent. of Lead Subacetate." *U. S.*

Aqua Saturnina; Goulard's Lotion, Goulard Water, *Br.*; Diluted Solution of Subacetate of Lead; Lotion à l'Acétate de Plomb, *Fr. Cod.*; Eau de Saturne, Eau de Goulard, Eau blanche, *Fr.*; Aqua Plumbi, *P. G.*; Bleiwasser, Kuhlwasser, *G.*

* "Solution of Lead Subacetate, *forty grammes* [or 1 ounce av., 180 grains]; Distilled Water, *a sufficient quantity*, to make *one thousand grammes* [or 35 ounces av., 120 grains]. Mix the Solution of Lead Subacetate with enough Distilled Water, previously boiled and

cooled, to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains]. Keep the Solution in well-stoppered bottles." *U. S.*

"Strong Solution of Lead Subacetate, 2 *fl. drachms* (Imperial measure) or 5 cubic centimetres; Alcohol (90 per cent.), 2 *fl. drachms* (Imp. meas.) or 5 cubic centimetres; Distilled Water, *a sufficient quantity*. Mix the Alcohol with *nineteen and a half fluid ounces* (Imp. meas.) or three hundred and ninety cubic centimetres of recently boiled and cooled Distilled Water; add the Strong Solution of Lead Subacetate and shake." *Br.*

In the *U. S. D.* comments on the *U. S.* process of 1850 it was stated that the strength of our official preparation, though double what it formerly was, might be still further increased with propriety. In the edition of the *U. S. Pharmacopœia* of 1870 the proportion was increased from two to three fluidrachms to the pint, and this proportion has been practically retained in the preparation now official. The direction to dilute the strong solution with distilled water *previously boiled and cooled* is an improvement, as even the small amount of carbon dioxide dissolved in distilled water usually made the lead water cloudy. Owing to the liability to serious results due to the frequent confounding of the name lime water and lead water, it is safer to dispense lead water in a slightly opalescent condition, while lime water should be perfectly transparent. The *Br.* preparation, though stronger than the old one of the London College, is still feeble. The minute proportion of alcohol in the British solution can have little effect. The preparation should be excluded from the air as much as possible.

LIQUOR POTASSII ARSENITIS. *U. S.* (*Br.*)

SOLUTION OF POTASSIUM ARSENITE [Fowler's Solution]

(lī'quor pō-tās'sī-i ār-se-nī'tis)

"An aqueous solution, which should contain Potassium Arsenite corresponding in amount to 1 percent. of arsenic trioxide." *U. S.* "110 minims contain 1 grain of Arsenious Anhydride; 100 cubic centimetres contain 1 gramme." *Br.*

Liquor Arsenicalis, *Br.*; Arsenical Solution; Solutio Arsenicallis Fowleri, Kali Arsenicosum Solutum; Soluté d'arsénite de Potasse, *Fr. Cod.*; Li-queur de Fowler, Liqueur arsenicale de Fowler, *Fr.*; Liquor Kali arsenicosi, *P. G.*; Fowlersche Tropfen, Fowlersche Lösung, *G.*; Soluzione alcalina di arsenito di potassio, Liquore del Fowler, *It.*; Solucion de arsenito potasico, Licor arsenical de Fowler, *Sp.*

* "Arsenic Trioxide, in fine powder, *ten grammes* [or 154 grains]; Potassium Bicarbonate, *twenty grammes* [or 309 grains]; Compound Tincture of Lavender, *thirty grammes* [or 1 ounce av., 26 grains]; Distilled Water, *a sufficient quantity*, to make *one thousand grammes* [or 35 ounces av., 120 grains]. Boil the Arsenic

Trioxide and Potassium Bicarbonate, in a tared dish, with *one hundred grammes* [or 3 ounces av., 231 grains] of Distilled Water, until solution has been effected. Then add enough Distilled Water to make the solution weigh *nine hundred and seventy grammes* [or 34 ounces av., 94 grains], and, lastly, add the Compound Tincture of Lavender. Filter through paper." *U. S.*

"Arsenious Anhydride, in powder, $87\frac{1}{2}$ grains (Imperial) or 10 grammes; Potassium Carbonate, $87\frac{1}{2}$ grains (Imp.) or 10 grammes; Compound Tincture of Lavender, 5 fl. drachms (Imp. meas.) or 31.25 cubic centimetres; Distilled Water, a sufficient quantity. Heat the Arsenious Anhydride and the Potassium Carbonate with *ten fl. ounces* (Imp. meas.) or five hundred cubic centimetres of Distilled Water in a one-pint (or one-litre) flask until a clear solution is obtained; cool; add the Compound Tincture of Lavender and sufficient Distilled Water to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Solution." *Br.* The sp. gr. of this solution is about 1.010.

This preparation originated with Fowler of Stafford, England, and was intended as a substitute for the celebrated remedy known under the name of "the tasteless aque drop." The strength of the present official solution is somewhat greater than that of the Fowler's solution of *U. S. P.* 1870; it now contains potassium arsenite corresponding in amount to 1 per cent. of arsenic trioxide, and the British solution has been made to correspond with this. It is a potassium arsenite dissolved in water, and is formed by the combination of the arsenic trioxide with the potassium of the bicarbonate or carbonate, carbon dioxide being evolved. In the present *U. S.* process the bicarbonate has been preferred to the carbonate, and in order to expedite the process the quantity has been doubled. As the bicarbonate is decomposed to carbonate by boiling water, there is present in the finished solution some potassium carbonate. According to M. H. Buignet, ebullition disengages the carbon dioxide slowly, so that after four hours' boiling the solution still retains about one-sixth of this gas. (*J. P. C.*, 1856, p. 440.) The name by which the preparation is designated in the *U. S. Pharmacopœia* is the more correct. The contact of arsenic trioxide with potassium bicarbonate in the presence of a small quantity of boiling water gives rise to effervescence with decomposition of bicarbonate. It has, however, been denied that potassium carbonate is decomposed by arsenic trioxide, which is supposed to be merely held by it in solution, and, in this view of the nature of the preparation, the British name of Arsenical Solution would be appropriate. The compound spirit of lavender is added to give it taste and prevent its being mistaken for water. For Oldberg's process, see *Proc. A. Ph. A.*, 1893, 430; see also *A. J. P.*, 1895, 403.

In making this preparation care should be taken that the arsenic trioxide is pure. This

object is best secured by using the form which comes in small pieces instead of the commercial powder, and powdering the lumps in a mortar. Calcium sulphate is a common impurity in the powdered oxide, and if present will remain undissolved, and cause the solution to be weaker than it should be. Another insoluble impurity in the powdered oxide is calcium arsenite, which is sometimes present to the amount of 25 per cent. (Buignet.) Hence, if the arsenic trioxide does not entirely dissolve the solution must be rejected.

Properties.—Solution of potassium arsenite is a transparent liquid, having slightly the color, taste, and odor of the compound tincture of lavender. It has an alkaline reaction. It is decomposed by the usual reagents for arsenic, by silver nitrate, the salts of copper, lime water, and hydrogen sulphide, and is incompatible with the infusions and decoctions of cinchona. Before hydrogen sulphide will act, the solution must be acidulated with some acid, as hydrochloric or acetic. "If 24.6 Gm. of Solution of Potassium Arsenite be diluted with water to 100 Cc., the mixture very slightly acidified with diluted hydrochloric acid, and then made alkaline with 2 Gm. of sodium bicarbonate, it should require not less than 50 Cc. of tenth-normal iodine V.S. to produce a permanent yellow tint (corresponding to 1 Gm. of arsenic trioxide in 100 Gm. of the solution)." *U. S.* "A reddish liquid, alkaline to test-papers, and having the odor of lavender. 25 cubic centimetres, neutralized with hydrochloric acid, and diluted with water, should discharge the color of 50.8 to 50.9 cubic centimetres of the volumetric solution of iodine, the presence of a slight excess of sodium bicarbonate being maintained throughout the operation. 110 minims contain 1 grain of Arsenious Anhydride; 100 cubic centimetres contain 1 gramme." *Br.* According to R. Fresenius, solutions of alkaline arsenites slowly absorb oxygen from the air, and are in part converted into arsenates. Hence the propriety of keeping this solution in small bottles well filled. Mohr states that the alkaline reaction of the official solution delays the change, and experience has confirmed this statement. The slight precipitate found in this solution after keeping proved to be silicic acid, caused by the action of the alkaline solution on the glass container.

Uses.—This solution has the general action of the arsenical preparations on the animal economy, already described under the head of *Arseni Trioxidum*. Its liquid form makes it convenient for exhibition and gradual increase, and it is the preparation generally resorted to when arsenic is given internally. It has been much employed in *intermittent fever*. In *chorea* it is almost a specific, and in *nervous diseases* of debility it is often very useful. In *malarial affections* and *chorea* it should be administered in ascending doses until the puffiness about the eyes or disturbance of the bowels betrays the arsenical impression. Fowler's solution is a

very valuable remedy in various skin diseases, and has the great advantage over the solid preparations that the dose may be readily increased from day to day. One hundred minims of the solution contain the equivalent of very nearly one grain of arsenic trioxide. For the peculiar effects upon the human organism, see *Arseni Trioxidum*.

Duflos's antidote to the poisonous effects of Fowler's solution, and of the salts of the acids of arsenic generally, is ferric acetate with excess of base, made by dissolving freshly precipitated ferric hydroxide in acetic acid to saturation, adding an equal quantity of the hydroxide to the solution, and diluting the whole with water to the consistence of cream. If the official solution of ferric acetate be used in an emergency, the free acid should first be neutralized with a little ammonia.

Dose, of potassium arsenite solution, three to five minims (0.2 to 0.3 Cc.).

LIQUOR POTASSII CITRATIS. U. S.

SOLUTION OF POTASSIUM CITRATE
[Neutral Mixture]

(Liquor po-tās-si-i cī-trā'tis)

"An aqueous liquid, containing in solution not less than 8 percent. of anhydrous Potassium Citrate $[\text{C}_6\text{H}_4(\text{OH})(\text{COOK})_3 = 304.2]$, with small amounts of citric and carbonic acids." U. S.

Mistura Potassii Citratiss; Liquor Kalii Citrici; Citrate de Potasse liquide, Fr.; Flüssiges Citronensaures Kali, Kaliumcitratlösung, G.

* "Potassium Bicarbonate, eight grammes [or 123 grains]; Citric Acid, six grammes [or 92 grains]; Distilled Water, a sufficient quantity, to make one hundred cubic centimeters [or 3 fluidounces, 183 minims]. Dissolve the Potassium Bicarbonate and the Citric Acid, each, in forty cubic centimeters [or 1 fluidounce, 169 minims] of Distilled Water. Filter the solutions separately, and wash the filters with enough Distilled Water to obtain, in each case, fifty cubic centimeters [or 1 fluidounce, 331 minims]. Finally, mix the two solutions, and, when effervescence has nearly ceased, transfer the liquid to a bottle. This preparation should be freshly made when wanted." U. S.

Solution of Potassium Citrate has been made identical with the mixture formerly official as *Mistura Potassii Citratiss*; nevertheless, the mixture made with lemon juice will continue to be preferred by some practitioners; its formula is therefore retained here as a foot-note.¹ The

official solution is stronger than the mixture, and is more definite in composition; lemon juice varies in strength, and consequently the amount of potassium citrate in the resulting mixture cannot be uniform. On the other hand, the mixture is much to be preferred on account of its more agreeable taste. An improvement has been made in the present official solution in directing the acid and the alkaline salt to be dissolved separately, and the direction to dispense the preparation in a fresh condition will undoubtedly lead to the keeping of the filtered solutions, by the pharmacist, in separate bottles, and mixing in equal measures or weights when prescribed. The solutions keep well for a considerable length of time, and the greater convenience and saving of time and labor, besides

and carbon dioxide is liberated. The result, therefore, is a solution of potassium citrate in water impregnated with carbon dioxide, with the flavor from the lemon juice. The solution has a greenish-yellow color, and it is not usually dispensed in a perfectly transparent condition, owing to the difficulty of filtering out the very fine albuminous precipitate found in lemon juice. About 48 grains of the crystals of the bicarbonate, 33 grains of the pure and perfectly dry carbonate, or 45 grains of the hydrated carbonate found in commerce, are sufficient to saturate a fluidounce of good lemon juice, but the strength of the juice is variable, and the carbonate is apt to absorb moisture from the air, so that precision as to quantities cannot be readily attained. Hence the propriety of the direction, in the process for the neutral mixture, to add the alkaline carbonate to saturation. The point of saturation may be determined by the cessation of effervescence, by the absence of either an acid or an alkaline taste, and still more accurately by litmus paper, which should not be rendered bright red by the solution, or blue if previously reddened by an acid. The inequality of strength in the lemon juice renders the neutral mixture prepared with it more or less uncertain, though, if the apothecary selects ripe and sound fruit, and expresses the juice himself, the preparation will be found to approach sufficiently near a uniform standard for all practical purposes. Nevertheless, if the physician wishes absolute precision, he may order the neutral mixture to be made with crystallized citric acid, as directed in *Liquor Potassii Citratiss*; or he may pursue the following plan, suggested in former editions of this work. Dissolve two drachms of potassium bicarbonate in two fluidounces of water; saturate the solution with good fresh lemon juice and strain; and, lastly, add enough water to make the mixture measure six fluidounces. A fluidounce is the dose of this solution.

EFFERVESCING DRAUGHT.—Under this name, potassium citrate is often prepared extemporaneously, and given in the state of effervescence. The most convenient mode of exhibition is to add to a fluidounce of a mixture consisting of equal parts of lemon juice and water, half a fluidounce of a solution containing fifteen grains of potassium carbonate, or twenty grains of the bicarbonate. Should effervescence not occur, as sometimes happens, when the carbonate is used, in consequence of the weakness of the lemon juice, more of the juice should be added; as, unless sufficient acid be present to neutralize the alkalinity, part of the carbonate will pass into the state of bicarbonate, and the gas be prevented from escaping. The fifteen grains of potassium carbonate above mentioned are scarcely sufficient to saturate the lemon juice, if of ordinary strength; but a little excess of the acid renders the preparation more agreeable to the taste. Some prefer the bicarbonate in the preparation of the effervescing draught, because it will always effervesce with lemon juice, no matter what may be the strength of the latter. But this is an objection. The carbonate serves, by the absence of effervescence, to indicate when the lemon juice is very weak in acid, and the defect may then be easily remedied by the addition of more juice. When the bicarbonate is used, if there should be a deficiency of acid, it is not discovered, and the patient takes a considerable portion of undecomposed bicarbonate, instead of the full quantity of citrate intended.

¹ *Mistura Potassii Citratiss*, U. S. 1880. *Mixture of Citrate of Potassium.* [Neutral Mixture.] *Mistura Neutralis; Potio gazeuse (effervescente),* Fr.

"Fresh Lemon Juice, strained, one hundred parts [or four fluidounces]; Bicarbonate of Potassium, about ten parts, or, a sufficient quantity. Add the Bicarbonate of Potassium gradually to the Lemon Juice until it is neutralized. This preparation should be freshly made, when wanted for use."

In this preparation the potassium of the bicarbonate unites with the citric acid of the lemon juice

the satisfaction of dispensing an effervescing solution, will be strong inducements to adopt this course.

Properties.—The U. S. Pharmacopœia describes the solution as “a clear, colorless liquid, odorless, having a mildly saline taste, and a slightly acid reaction. It should conform to the reactions and tests for an aqueous solution of the salt given under *Potassii Citras*. If 10.14 Gm. of Solution of Potassium Citrate be evaporated to dryness and then thoroughly carbonized at a temperature not exceeding a low red heat, and the residue extracted with boiling distilled water until the washings cease to react with methyl-orange T.S., the filtrate should require, for complete neutralization, not less than 16 Cc. of half-normal sulphuric acid V.S., methyl-orange T.S. being used as indicator (each Cc. of the half-normal sulphuric acid V.S. consumed representing 0.5 percent. of anhydrous Potassium Citrate).” U. S.

Uses.—The solution of potassium citrate has long been used under the name of *neutral mixture, saline mixture, or effervescing draught*. It formerly was much used as a refrigerant diaphoretic, in cases of fever with dry skin, but has been largely superseded by the more potent antipyretics. In some cases, however, it makes a useful vehicle for the administration of antipyrine and similar drugs. The *effervescing draught* is especially valuable in malarial, remittent and other fevers, when there is great irritability of the stomach. The whele of the effervescing draught made in accordance with the formula (page 732) may be taken at once, the dose being repeated in from one to three hours according to the symptoms.

Dose, of official solution, four fluidrachms (15 Cc.).

LIQUOR POTASSII HYDROXIDI.

U. S. (Br.)

SOLUTION OF POTASSIUM HYDROXIDE

[Liquor Potassæ, Pharm. 1890, Solution of Potassa]

(LI'quor po-tās'si-I hÿ-drōx'i-dī)

“An aqueous solution, containing about 5 percent. of Potassium Hydroxide [KOH = 55.74].” U. S. “An aqueous solution containing in 110 minims 6.2 grains, or in 1 fluid ounce 27 grains of potassium hydroxide, KOH.” Br.

Liquor Potassæ, Br.; Kali Hydricum Solutum, Lixivum Causticum; Solution of Potash; Potasse caustique liquide, Lessive caustique, Fr.; Liquor Kali Caustici, P. G.; Aetzkalilauge, Kallilauge, G.

* “Potassium Hydroxide, sixty grammes [or 2 ounces av., 51 grains]; Distilled Water, nine hundred and forty grammes [or 33 ounces av., 69 grains], to make one thousand grammes [or 35 ounces av., 120 grains]. Dissolve the Potassium Hydroxide in the Distilled Water. The Potassium Hydroxide used in this process should be of the full strength and quality directed by the Pharmacopœia (85 percent.).

Potassium Hydroxide of any other strength, however, may be used, if a proportionately larger or smaller quantity be taken, the proper amount for the above formula being ascertained by dividing 5100 by the percentage of absolute Potassium Hydroxide contained therein. Solution of Potassium Hydroxide should be kept in bottles made of green glass, and provided with glass stoppers coated with paraffin or petrolatum.” U. S.

In the U. S. P. (8th Rev.) the only process for making this solution is the simple one of dissolving potassium hydroxide in sufficient distilled water to make a 5 per cent. solution, the former process of decomposing potassium bicarbonate with lime and mixing with water having been dropped. As this is sometimes used it is appended.¹

The British Pharmacopœia 1898 does not give a detailed process, merely specifying that one fluidounce shall contain twenty-seven grains of potassium hydroxide.

According to Wöhler, solution of pure potassium hydroxide for analytical purposes may be conveniently obtained by exposing for half an hour to a moderate red heat, in a copper crucible, one part of pure potassium nitrate, and two or three parts of copper cut into small pieces. The resulting mass, consisting of potassium hydroxide and black oxide of copper, is treated with water, and the solution poured into a narrow cylindrical vessel, where it is left until it gets perfectly clear by the deposition of the oxide of copper. It is then drawn off, and kept in well-stoppered bottles. (*Chem. Gaz.*, Nov. 15, 1853, p. 429.) Graf and Riegel assert that potassium hydroxide, thus obtained, contains potassium nitrate and nitrite, but A. Geuther found it perfectly pure, when the process was properly conducted. (*Chem. Gaz.*, June 1, 1856.) A pure hydroxide may also be obtained by the process of Mohr, which consists in precipitating solution of potassium sulphate with caustic baryta, obtained from the nitrate. Thus procured, the alkali is entirely free from chlorine, silica, and sulphuric acid. (P. J., xvi. 310.)

¹ *Liquor Potassæ*, U. S. P. 1890.—An aqueous solution of Potassium Hydrate [KOH = 55.99] containing about 5 per cent. of the hydrate. “Potassium Bicarbonate, eighty-five grammes [or 3 ounces av.]; Lime, forty grammes [or 1 ounce av., 180 grains]; Distilled Water, a sufficient quantity. Dissolve the Potassium Bicarbonate in four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Distilled Water, heat the solution until effervescence ceases, and then increase the heat to the boiling point of the liquid. Slake the Lime with about twenty cubic centimeters [or 825 minims] of Distilled Water, then mix it well with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Distilled Water, pour the mixture into a tared flask, and, having heated it to boiling, gradually add to it the solution of Potassium Bicarbonate, and boil during ten minutes. Then add enough Distilled Water to the flask to make the contents weigh one thousand grammes [or 35 ounces av., 120 grains], and set the flask aside, well stoppered, until the contents are cold. Lastly, strain the liquid through linen, set it aside in a well-stoppered bottle until it has become clear by subsidence, and separate the clear solution by decantation, or by means of a siphon.” U. S. 1890.

Properties.—Solution of potassium hydroxide is “a clear, colorless liquid, odorless, having a very acrid and caustic taste, and a strongly alkaline reaction. Specific gravity: about 1.046 at 25° C. (77° F.). It should conform to the reactions and tests for an aqueous solution of potassium hydroxide given under *Potassii Hydroxidum*. To neutralize 28 (27.87) Gm. of Solution of Potassium Hydroxide should require about 25 Cc. of normal sulphuric acid V.S., methyl-orange T.S. being used as indicator (each Cc. of normal sulphuric acid V.S. indicating 0.2 percent. of absolute Potassium Hydroxide).” *U. S.* “A colorless, odorless, and transparent liquid having a nauseous taste. It is strongly alkaline. It should not yield any characteristic reaction with the tests for lead, copper, arsenium, iron, aluminium, calcium, magnesium, sodium, or ammonium, and should be free from more than traces of carbonates, chlorides, or sulphates. Specific gravity 1.058. 9 cubic centimetres should require for neutralization 10 cubic centimetres of the volumetric solution of sulphuric acid, corresponding to 0.557 gramme of potassium hydroxide, KOH, or to 6.19 grammes in 100 cubic centimetres, or to 5.85 grammes in 100 grammes. Solution of Potash should be preserved in a green glass bottle furnished with an air-tight stopper.” *Br.* It acts rapidly on animal and vegetable substances, and when rubbed between the fingers produces a soapy feeling, in consequence of a partial solution of the cuticle. It dissolves gum, resins, and extractive matter, and forms soap with oily and fatty bodies. Lead may be detected by a black precipitate produced by ammonium sulphhydrate. When solution of potassium hydroxide is used as a test for diabetic urine, it should be free from lead, the presence of which renders the test ambiguous. With hydrochloric acid and platonic chloride it produces a yellow precipitate, showing that the alkali present is potassium hydroxide. It is incompatible with acids, acidulous salts, and all metallic and earthy salts held in solution by an acid; also with all ammoniacal salts, and with calomel and corrosive sublimate. The two official solutions of potassium hydroxide vary in strength, the *U. S.* solution having the sp. gr. 1.046 at 25° C. (77° F.) and the *Br.* 1.058. These solutions are very dilute, that of the *U. S.* Pharm., which is the weaker, containing only 5 per cent. of potassium hydroxide; the percentage of potassium hydroxide in the solution of the *Br. Pharm.* is 5.85. On account of its strong attraction for carbon dioxide, solution of potassium hydroxide should be carefully preserved from contact with the air.

Uses.—Solution of potassium hydroxide is antacid, diuretic, and antilithic, and was formerly much used, but, on account of its irritant properties, has been superseded by the carbonated alkalis.

Dose, ten to thirty minims (0.6 to 1.8 Cc.).

Off. Prep.—Fluidextractum Senegæ, *U. S.*

LIQUOR POTASSII PERMANGANATIS.

Br.

SOLUTION OF POTASSIUM PERMANGANATE

(l'iquor pō-tās'sī-i pēr-mān'gā-nā'tis)

Soluté de Permanganate de Potasse, *Fr.*; Kallium permanganatlösung, *G.*

“Potassium Permanganate, 87½ grains (Imperial) or 10 grammes; Distilled Water, a sufficient quantity. Dissolve the Potassium Permanganate in sufficient Distilled Water to produce one pint (Imp. meas.) or one thousand cubic centimetres of the Solution. 110 minims contain 1 grain of potassium permanganate; 100 cubic centimetres contain 1 gramme.” *Br.*

This is an unstable 1 per cent. solution of potassium permanganate which decomposes upon exposure and deposits manganese oxides.

Dose, of the British Pharmacopœia, from two to four fluidrachms (7.5 to 15 Cc.), equivalent to from 1.1 to 2.2 grains of the salt. Very few stomachs will bear more than one grain (0.065 Gm.) of the permanganate.

LIQUOR QUASSIÆ CONCENTRATUS.

Br.

CONCENTRATED SOLUTION OF QUASSIA

(l'iquor quās'sī-æ cōn-cēn-trā'tūs)

“Quassia Wood, in No. 40 powder, 2 ounces (Imperial) or 100 grammes; Alcohol (20 per cent.), 22 fl. ounces (Imp. meas.) or 1100 cubic centimetres or a sufficient quantity. Mix the Quassia with two fluid ounces (Imp. meas.) or one hundred cubic centimetres of the Alcohol; pack in a closed percolator; set aside for three days; percolate with the remaining Alcohol, added in ten equal portions at intervals of twelve hours; continue percolation with more Alcohol until the product measures one pint (Imp. meas.) or one thousand cubic centimetres.” *Br.*

This solution was introduced into the British Pharmacopœia 1898 mainly to facilitate the preparation of infusion of quassia by diluting the solution with water.

Dose, from one-half to one fluidrachm (1.8 to 3.75 Cc.).

LIQUOR RHEI CONCENTRATUS. *Br.*

CONCENTRATED SOLUTION OF RHUBARB

(l'iquor rhē'i cōn-cēn-trā'tūs)

“Rhubarb Root, in No. 5 powder, 10 ounces (Imperial) or 500 grammes; Alcohol (20 per cent.), 25 fl. ounces (Imp. meas.) or 1250 cubic centimetres or a sufficient quantity. Moisten the Rhubarb with five fl. ounces (Imp. meas.) or two hundred and fifty cubic centimetres of the Alcohol; pack in a closed percolator; set aside for three days; percolate with the remaining Alcohol, added in ten equal portions at in-

tervals of twelve hours; continue percolation with more Alcohol until the product measures *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This solution has been introduced into the British Pharmacopœia to facilitate the preparation of the infusion of rhubarb. (See p. 656.) F. C. J. Bird finds that the concentrated solution of rhubarb when prepared by the method of the Brit. Pharm. cannot be considered quite satisfactory, for, on keeping, it almost invariably throws down a brownish-yellow deposit. Moreover, experimental data, which are given in the form of a table, show that only about 60 per cent. of the available extractive of the root is contained in the Br. Pharm. solution. The author finds the addition of glycerin most effective to prevent the formation of a precipitate, and recommends a modification of the official formula, according to which the first 17 fl. oz. of percolate are reserved, the subsequent 3 fl. oz. of percolate evaporated to a soft extract, which is dissolved in 3 fl. oz. of glycerin and added to the reserved portion so as to make 20 fl. oz. of finished product. A sample of liquor so prepared has remained quite free from deposit for several months. (*Y. B. P.*, 1903, 496.)

Dose, from one-half to one fluidrachm (1.8 to 3.75 Cc.).

LIQUOR SARSÆ COMPOSITUS CONCENTRATUS. *Br.*

CONCENTRATED COMPOUND SOLUTION OF SARSAPARILLA

(*l'iquor sār-sæ cōm-pōs'it-tūs cōn-cēn-trā'tūs*)

"Sarsaparilla, cut transversely and bruised, 20 ounces (Imperial) or 1000 grammes; Sassafras Root, in shavings, 2 ounces (Imp.) or 100 grammes; Guaiacum Wood, in shavings, 2 ounces (Imp.) or 100 grammes; Dried Liquorice Root, bruised, 2 ounces (Imp.) or 100 grammes; Mezereon Bark, cut small, 1 ounce (Imp.) or 50 grammes; Alcohol (90 per cent.), 4½ fl. ounces (Imp. meas.) or 225 cubic centimetres; Distilled Water, a sufficient quantity. Infuse the Sarsaparilla in three successive portions of *five pints* (Imp. meas.) or five litres of the Distilled Water, for one hour each, at 160° F. (71.1° C.). Boil the other solid ingredients with Distilled Water until exhausted. Rapidly concentrate the mixed infusion and decoction until, when cold, the liquid measures *sixteen fluid ounces* (Imp. meas.) or eight hundred cubic centimetres; add the Alcohol; set aside for at least fourteen days; filter. The product should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This preparation was introduced into the British Pharmacopœia 1898 to provide a reasonably stable solution from which the decoction can be made by dilution.

Precipitation is apt to occur on standing. The precipitate is, however, inert and may be filtered out.

Dose, of the solution, from two to eight fluidrachms (7.5 to 30 Cc.).

LIQUOR SENEGÆ CONCENTRATUS.

Br.

CONCENTRATED SOLUTION OF SENEGA

(*l'iquor sēn'ē-gæ cōn-cēn-trā'tūs*)

"Senega Root, in No. 20 powder, 10 ounces (Imperial) or 500 grammes; a mixture of two parts of Alcohol (20 per cent.) and one part of Alcohol (45 per cent.), 25 fl. ounces (Imp. meas.) or 1250 cubic centimetres or a sufficient quantity. Moisten the Senega with *four fluid ounces* (Imp. meas.) or two hundred cubic centimetres of the menstruum; pack in a closed percolator; set aside for three days; percolate with the remaining menstruum, added in ten equal portions at intervals of twelve hours; continue percolation with more menstruum until the product measures *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This solution was introduced into the Br. Ph. 1898 for the purpose of providing a method of making the infusion by simple dilution.

Dose, from one-half to one fluidrachm (1.8 to 3.75 Cc.).

LIQUOR SENNÆ CONCENTRATUS. *Br.*

CONCENTRATED SOLUTION OF SENNA

(*l'iquor sēn'næ cōn-cēn-trā'tūs*)

"Senna, in No. 5 powder, 20 ounces (Imperial) or 1000 grammes; Tincture of Ginger, 2½ fl. ounces (Imp. meas.) or 125 cubic centimetres; Alcohol (90 per cent.), 2 fl. ounces (Imp. meas.) or 100 cubic centimetres; Distilled Water, a sufficient quantity. Divide the Senna into three equal portions; slightly moisten one portion with Distilled Water; pack in a percolator; set aside for twenty-four hours; pass Distilled Water through it until *five fluid ounces* (Imp. meas.) or two hundred and fifty cubic centimetres are obtained. Slightly moisten the second portion of Senna with this liquid; pack in a percolator; set aside for twenty-four hours; percolate with the remainder of the liquid obtained from the first portion, and also with an additional *five fluid ounces* (Imp. meas.) or two hundred and fifty cubic centimetres obtained by passing more Distilled Water through the first portion. Repeat the process with the third portion of the Senna, and continue successive percolation through the three portions, until a quantity of *sixteen fluid ounces* (Imp. meas.) or eight hundred cubic centimetres has been collected from the third percolator. Heat the liquid to

180° F. (82.2° C.) for five minutes; cool; add the Alcohol and Tincture of Ginger, previously mixed; set aside for seven days; filter. The product should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This solution was introduced into the British Pharmacopœia mainly to provide a strong stable solution from which the infusion may be made by dilution. (See p. 657.) This preparation is an excellent laxative and purgative. According to F. C. J. Bird this is the most unsatisfactory of the *Br. Pharm.* liquors, on account of its unstable qualities and the deposition, with loss of extractive, when kept for any length of time. Another weak point is found in the process itself, which requires the maceration of the senna leaves with distilled water for a period requiring at least seventy-two hours, or probably much more, if the official directions are strictly followed. In consequence of this prolonged exposure, especially if such be during warm weather, the infusion is liable to decomposition, before it is finished. The process of extraction adopted for the senna is also less efficient than in the case of any of the other liquors, notwithstanding that the extraction is effected by repercolation, for the product, as shown experimentally, contains only from 55 to 56 per cent. of the available extractive of the leaves. With the view to remedying some of these defects, he suggested that chloroform water should be used instead of distilled water, the chloroform to be driven off by heating to 180° F., as is now directed; that the quantity of alcohol to be added be increased in the formula from 2 fl. oz. to 2½ fl. oz., and that the filtered product, after standing seven days, be again heated to 180° F. in a closed vessel for half an hour or longer until the precipitate aggregates and the supernatant liquor becomes transparent; the product is brilliantly clear, and keeps for months without change. (*Y. B. P.*, 1903, 496.)

Dose, from one-half to one fluidrachm (1.8 to 3.75 Cc.).

LIQUOR SERPENTARIÆ CONCENTRATUS. *Br.*

CONCENTRATED SOLUTION OF SERPENTARY

(l'quor sēr-pen-tā-rī-æ cōn-cēn-trā'tūs)

"Serpentary Rhizome, in No. 40 powder, 10 ounces (Imperial) or 500 grammes; Alcohol (20 per cent.), 25 fl. ounces (Imp. meas.) or 1250 cubic centimetres or a sufficient quantity. Moisten the Serpentry with five fluid ounces (Imp. meas.) or two hundred and fifty cubic centimetres of the Alcohol; pack in a closed percolator; set aside for three days; percolate with the remaining Alcohol, added in ten equal portions at intervals of twelve hours; continue percolation with more Alcohol until the product measures *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

This solution was introduced into the British Pharmacopœia mainly to facilitate the preparation of the infusion. (See p. 658.)

Dose, from one-half to two fluidrachms (1.8 to 7.5 Cc.).

LIQUOR SODÆ CHLORINATÆ.

U. S., *Br.*

SOLUTION OF CHLORINATED SODA
[Liquor Sodæ Chloratæ, *Pharm.* 1890, *Labarraque's Solution*]

(l'quor sō'dæ çhlō-rī-nā'tæ)

"An aqueous solution of several chlorine compounds of sodium, containing at least 2.4 percent., by weight, of available chlorine." *U. S.*

Liquor Natri Chlorati; Liquor Natri Hypochlorosi; Bleaching Solution; Chlorure de Soude liquide, *Fr. Cod.*; Liqueur de Labarraque, *Fr.*; Chloratron-lösung, Bleichflüssigkeit, *G.*; Solución de hipoclorito sodico, Licor de Labarraque, *Sp.*

* "Monohydrated Sodium Carbonate, *sixty-five grammes* [or 2 ounces av., 128 grains]; Chlorinated Lime, *ninety grammes* [or 3 ounces av., 76 grains]; Water, a sufficient quantity, to make *one thousand grammes* [or 35 ounces av., 120 grains]. Triturate the Chlorinated Lime (which should contain not less than 30 percent. of available chlorine) with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, gradually added, until a uniform mixture results. Allow the heavier particles to subside, and transfer the thinner, supernatant portion to a filter. Then triturate the residue again with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, transfer the whole to the filter, and, when the liquid has drained off, wash the filter and contents with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Water. Dissolve the Monohydrated Sodium Carbonate in *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of hot Water, and add this solution to the previously obtained filtrate contained in a suitable vessel. Stir or shake the mixture thoroughly, and, if it should become gelatinous, warm the vessel very gently, until the precipitate subsides. Then transfer the mixture to a new filter, and, when no more liquid drains from it, wash the filter and contents with enough Water to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains]. Keep the Solution in well-stoppered bottles, protected from light, and in a cool place." *U. S.*

"Chlorinated Lime, 16 ounces (Imperial) or 400 grammes; Sodium Carbonate, 24 ounces (Imp.) or 600 grammes; Distilled Water, 1 gallon (Imp. meas.) or 4 litres. Dissolve the Sodium Carbonate in one-quarter of the Distilled Water; thoroughly triturate the Chlorinated Lime with the remainder of the Distilled Water; mix the two liquids; filter." *Br. Sp. gr.* 1.054 at 15.5° C. (60° F.).

This solution was first brought into notice as a disinfecting agent by Labarraque, an apothecary of Paris. It was afterwards found to possess valuable therapeutic properties. The U. S. process is practically that of Payen, adopted in the French Codex of 1837. It consists in decomposing a solution of monohydrated sodium carbonate by one of chlorinated lime. Calcium carbonate is precipitated and the chlorinated soda remains in solution. The proportion employed gives an excess of sodium carbonate, the presence of which renders the solution more permanent. Sodium bicarbonate has been recommended instead of sodium carbonate, on account of the state of crystalline powder in which the calcium carbonate is precipitated, rendering its separation from the supernatant solution very easy, while the precipitate produced by sodium carbonate is a kind of magma from which the liquor is not readily decanted. It is stated also that a little excess of the bicarbonate is useful in various ways. (*Ann. Thér.*, 1866, 107.)

Properties.—The U. S. solution is “a clear, pale greenish liquid, having a faint odor of chlorine, and a disagreeable, alkaline taste. Specific gravity: about 1.050 at 25° C. (77° F.). The Solution at first colors red litmus paper blue, and then bleaches it. The addition of hydrochloric acid to the Solution causes an evolution of chlorine and carbon dioxide. If 7 Gm. of the Solution be mixed with 50 Cc. of water, and 2 Gm. of potassium iodide and 10 Cc. of hydrochloric acid be added, not less than 48 Cc. of tenth-normal sodium thiosulphate V.S. should be required to discharge the final yellow color of the liquid (each Cc. of the tenth-normal sodium thiosulphate V.S. corresponding to 0.05 percent. of available chlorine).” *U. S.* “A colorless alkaline liquid, with astringent taste and faint odor of chlorine. It decolorizes solution of indigo sulphate. It is decomposed by hydrochloric acid, evolving chlorine. It should yield not more than the slightest reaction with the tests for calcium or for carbonates. Specific gravity 1.054. If 3.5 grammes be added to a solution of 1 gramme of potassium iodide in 100 cubic centimetres of water acidulated with 3 cubic centimetres of hydrochloric acid, a brownish-red color should be produced, for the discharge of which at least 25 cubic centimetres of the volumetric solution of sodium thiosulphate should be required, corresponding to about 2½ per cent. of available chlorine.” *Br.* This test, like that of our own Pharmacopœia, is intended to determine the chlorine strength of the solution. The hydrochloric acid liberates the chlorine, which then liberates from the potassium iodide an equivalent quantity of iodine, by which the solution is rendered brown, and, the iodine being converted into hydriodic acid by the sodium thiosulphate, the solution again becomes colorless. The quantity of the solution of the latter salt required to bleach the liquid measures the amount of iodine, and

this, that of the chlorine which has separated it. The color of turmeric is first rendered brown, and afterwards destroyed. When carefully evaporated, a mass of damp crystals is obtained, which, when redissolved in water, possesses the properties of the original liquid. Solution of chlorinated soda, when exposed to the air, absorbs carbon dioxide and slowly evolves chlorine which acts as a disinfectant.

Nature and Composition.—In their chemical nature these solutions are identical. Assuming the chlorinated lime to be essentially calcium hypochlorite with calcium chloride (see page 268), the solutions, after decantation from the precipitated calcium carbonate, will contain sodium hypochlorite with sodium chloride:

Besides these there will be present more or less sodium carbonate, according as there happens to be in the chlorinated lime less or more chlorine to decompose it. In all cases, however, there will be an excess of sodium carbonate, as the best chlorinated lime does not contain sufficient chlorine to effect its entire decomposition, in the proportion in which it is taken in the formula.

Uses.—Solution of chlorinated soda possesses the medicinal properties of chlorinated lime, *i.e.*, dependent on its available chlorine. Formerly it was used internally in various conditions of *adynamia* and *zymosis*; it is, however, at present rarely so given. As a local remedy it is very actively stimulant and antiseptic, and has been used to a considerable extent not only in the treatment of external infected wounds or ulcers but also in infected conditions of the vagina, uterus, bladder, mouth, fauces, and other cavities which can be reached from the outside. Usually in these cases it should be diluted with from 15 to 30 parts of water, and when it is employed in indefinite quantity, as in washing out the bladder by means of the double canula, half an ounce is sufficient in one and a half pints of water. When used by means of lint or in other ways for the treatment of skin eruptions, the dilution should contain from 10 to 30 per cent.

Dose, ten to twenty minims (0.6 to 1.3 Cc.).

LIQUOR SODII ARSENATIS. U. S., Br.

SOLUTION OF SODIUM ARSENATE

(Liquor sō'di-i ār-se-nā'tis)

“An aqueous solution, which should contain Sodium Arsenate corresponding in amount to not less than 1 percent. of Exsiccated Sodium Arsenate.” *U. S.* “110 minims contain 1.77 grains of crystallized sodium arsenate, ($\text{Na}_2\text{HAsO}_4, 7\text{H}_2\text{O}$) or the equivalent of one grain of the anhydrous salt. 100 cubic centimetres contain 1.77 grammes of the crystallized salt, equivalent to 1 gramme of the anhydrous salt.” *Br.*

Liquor Sodii Arsenatis. *Br.* 1885: Solution of Arseniate of Sodium; Soluté d'arséniate de Soude, *Fr.*; Arsensäure Natronlösung, *G.*

* "Exsiccated Sodium Arsenate, *one gramme* [or 15.4 grains]; Distilled Water, *a sufficient quantity*, to make *one hundred grammes* [or 3 ounces av., 231 grains]. Dissolve the Exsiccated Sodium Arsenate in a sufficient quantity of Distilled Water to make the product weigh *one hundred grammes* [or 3 ounces av., 231 grains]." U. S.

"Sodium Arsenate, recently rendered anhydrous, $17\frac{1}{2}$ grains (Imperial) or 1 gramme; Distilled Water, *a sufficient quantity*. Dissolve the anhydrous Sodium Arsenate in sufficient Distilled Water to produce *four fluid ounces* (Imp. meas.) or one hundred cubic centimetres of the Solution of Sodium Arsenate." Br.

This is simply an official form for the administration of sodium arsenate. (See *Sodii Arsenas* and *Sodii Arsenas Exsiccatus*.) "The Solution should conform to the reactions and tests for an aqueous solution of the salt given under *Sodii Arsenas Exsiccatus*." U. S. The present official solution is somewhat stronger than that of the U. S. P. 1870. It now contains 1 per cent. of exsiccated sodium arsenate, where formerly there was present but 0.87 per cent., and the British solution has been made to correspond in strength. The salt is directed to be dried, in order that the solution may be of a uniform strength, as, from the mode in which the sodium arsenate is ordered to be prepared, it is scarcely possible that it should always contain precisely the same quantity of water of crystallization. It is important in drying it to limit the heat to 302° F., lest a portion of the arsenic should be volatilized.

Dose, from three to five minims (0.2 to 0.3 Cc.), to be cautiously increased, if necessary.

LIQUOR SODII ETHYLATIS. Br.

SOLUTION OF SODIUM ETHYLATE

(l'iquor sô'di-i êth-y-lâ'tis)

Solution of Sodium Alcoholate; Soluté d'ethylate de soude, Fr.; Natriumethylatlösung, Natriumalkoholatlösung, G.

"Sodium, clean and bright, 22 grains (Imperial) or 1 gramme; Absolute Alcohol, 1 fl. ounce (Imp. meas.) or 20 cubic centimetres. Cautiously dissolve the Sodium in the Absolute Alcohol contained in a flask, the latter being kept cool by a stream of cold water." Br.

This preparation was introduced into the British Pharmacopœia in 1885. It is described as "a colorless liquid of syrupy consistence, becoming brown by keeping. Specific gravity 0.867. When slightly heated it boils and gives off alcoholic vapors, leaving a white residue which, on being strongly heated, becomes charred. If the white residue be mixed with water and heated, it yields ethylic alcohol, and the solution, on evaporation, leaves a white residue consisting almost wholly of caustic soda. This solution should be recently prepared. It contains 18 per cent. of the solid substance, CaH_2ONa ." Br. It may be made more conven-

iently by dissolving twenty grains of sodium ethylate in eighty grains of absolute alcohol. It is used solely as a caustic, and is said to produce very little pain. No water should be allowed to come in contact with it.

LIQUOR SODII HYDROXIDI. U. S.

SOLUTION OF SODIUM HYDROXIDE

[Liquor Sodæ, Pharm. 1890, Solution of Soda]

(l'iquor sô'di-i hy-drôx'-i-di)

"An aqueous solution, containing about 5 percent. of Sodium Hydroxide [$\text{NaOH} = 39.76$]." U. S.

Solution of Caustic Soda; Natrium Hydricum Solutum; Soude caustique liquide, Fr. Cod.; Lessive des Savonniers, Fr.; Liquor Natrii Caustici, P. G.; Aetznatronlauge, Natronlauge, G.; Solucion de sosa caustica, Sp.

* "Sodium Hydroxide, *fifty-six grammes* [or 1 ounce av., 427 grains]; Distilled Water, *nine hundred and forty-four grammes* [or 33 ounces av., 130 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Dissolve the Sodium Hydroxide in the Distilled Water. The Sodium Hydroxide used in this process should be of the full strength and quality directed by the Pharmacopœia (90 percent.). Sodium Hydroxide of any other strength, however, may be used, if a proportionately larger or smaller quantity be taken; the proper amount for the above formula being ascertained by dividing 5040 by the percentage of absolute Sodium Hydroxide contained therein. Solution of Sodium Hydroxide should be kept in bottles made of green glass, and provided with glass stoppers coated with paraffin or petrolatum." U. S.

The process for Solution of Soda U. S. P. 1890 is appended.¹

Solution of sodium hydroxide is prepared in the same way as solution of potassium hydroxide. In the U. S. P. (8th Rev.) the process is that of simple solution of sodium hydroxide in water; in the U. S. P. 1890 process by a double decomposition between sodium

¹ *Liquor Sodæ*, U. S. 1890. *Solution of Sodium Hydrate*.—"An aqueous solution of Sodium Hydrate [$\text{NaOH} = 39.96$] containing about 5 per cent. of the hydrate." U. S.

"Sodium Carbonate, *one hundred and seventy grammes* [or 6 ounces av., 153 grains]; Lime, *fifty grammes* [or 1 ounce av., 384 grains]; Distilled Water, *a sufficient quantity*. Dissolve the Sodium Carbonate in *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of boiling Distilled Water. Slake the Lime with about *thirty cubic centimeters* [or 1 fluidounce, 7 minims] of Distilled Water, then mix it well with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Distilled Water, pour the mixture into a tared flask, and, having heated it to boiling, gradually add to it the solution of Sodium Carbonate, and boil during ten minutes. Then add enough Distilled Water to the flask to make the contents weigh *one thousand grammes* [or 35 ounces av., 120 grains], and set the flask aside, well stoppered, until the contents are cold. Lastly, strain the liquid through linen, set it aside in a well-stoppered bottle until it has become clear by subsidence, and separate the clear solution by decantation, or by means of a siphon." U. S. 1890.

carbonate and calcium hydroxide, there are formed sodium hydroxide in solution, and calcium carbonate which precipitates:

In this process an excess of lime is used, which is necessary to insure a full decomposition of the carbonate.

Properties.—Solution of sodium hydroxide, sometimes called solution of caustic soda, is “a clear, colorless liquid, odorless, having a very acid and caustic taste, and a strongly alkaline reaction. Specific gravity: about 1.056 at 25° C. (77° F.). It should conform to the reactions and tests for an aqueous solution of sodium hydroxide given under *Sodii Hydroxidum*. To neutralize 20 (19.9) Gm. of Solution of Sodium Hydroxide there should be required about 25 Cc. of normal sulphuric acid V.S., methyl-orange T.S. being used as indicator (each Cc. of normal sulphuric acid V.S. indicating 0.2 percent. of absolute Sodium Hydroxide).” *U. S.* Its properties and tests are the same as those of solution of potassium hydroxide, with the exception that no precipitate is produced by platinic chloride or tartaric acid. The alkali dissolved must be viewed as sodium hydroxide (Na.OH), of which two molecules are formed by the union of the oxide with water, according to the reaction:

Dose, ten to thirty minims (0.6 to 1.8 Cc.).

Off. Prep.—Fluidextractum Taraxaci, *U. S.*; Oleum Terebinthinæ Rectificatum, *U. S.*

LIQUOR SODII PHOSPHATIS COMPOSITUS. U. S.

COMPOUND SOLUTION OF SODIUM PHOSPHATE

(*l'iquor sô'di-i phôs-phâ'tis côm-pô's'j-tûs*)

Soluté de Phosphate de Soude composé, *Fr.*; Zusammengesetzte Natriumphosphatlösung, *G.*

* “Sodium Phosphate, uneffloresced crystals, *one thousand grammes* [or 35 ounces av., 120 grains]; Sodium Nitrate, *forty grammes* [or 1 ounce av., 180 grains]; Citric Acid, *one hundred and thirty grammes* [or 4 ounces av., 256 grains]; Distilled Water, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Triturate the Sodium Phosphate and Sodium Nitrate, in a mortar, with the Citric Acid, until completely liquefied, then add sufficient Distilled Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Filter the liquid. Keep the Solution in well-stoppered bottles in a moderately warm place.” *U. S.*

Compound Solution of Sodium Phosphate is official for the first time in the *U. S. P.* (8th Rev.). Its introduction grew out of the necessity for a permanent solution of sodium phosphate, for this salt is slow in dissolving and valuable time is often wasted at the prescription desk on this account. The additions of sodium

nitrate and citric acid are for the purpose of the prevention of crystallization during cold weather. The solution contains 1 Gm. of sodium phosphate in 1 Cc. of solution or about 57 grains in a fluidrachm.

Properties.—“If to 1 Cc. of the Solution, diluted with an equal volume of water, a slight excess of ammonia water, followed by 1 Cc. of magnesia mixture T.S., be added, a white crystalline precipitate will be obtained. If 1 Cc. of the Solution, diluted with 5 Cc. of water, be mixed with an equal volume of sulphuric acid, and to the cooled mixture a crystal of ferrous sulphate be added, a dark brown zone will appear around the crystal. If 5 Cc. of the Solution be neutralized with ammonia water, an excess of calcium chloride T.S. added, and the mixture filtered, the filtrate, upon boiling, should deposit a white precipitate.” *U. S.*

Uses.—See *Sodii Phosphas*.

Dose, one to two fluidrachms (3.75 to 7.5 Cc.).

LIQUOR STRYCHNINÆ HYDRO- CHLORIDI. Br.

SOLUTION OF STRYCHNINE HYDROCHLORIDE

[Solution of Hydrochlorate of Strychnine, *Brit. Pharm.* 1885.]

(*l'iquor strý'ch-ni'næ hý-drô-phlô'r'i-dî*)

Liquor Strychninæ; Soluté de Chlorhydrate de Strychnine, *Fr.*; Salzsaure Strychninlösung, *G.*

“Strychnine Hydrochloride, 17½ grains (Imperial) or 1 gramme; Alcohol (90 per cent.), 1 fl. ounce (Imp. meas.) or 25 cubic centimetres; Distilled Water, *a sufficient quantity*. Dissolve the Strychnine Hydrochloride in the Alcohol mixed with sufficient Distilled Water to produce *four fluid ounces* (Imp. meas.) or one hundred cubic centimetres of the Solution of Strychnine Hydrochloride. 110 minims contain 1 grain of Strychnine Hydrochloride; 100 cubic centimetres contain 1 gramme.” *Br.*

This is the solution of hydrochloride of strychnine of the British Pharmacopœia which was formerly official as *Liquor Strychninæ*; the name has been made definite, and the strength slightly increased, so as to make it conform with the other active solutions; it contains about 1 per cent. of strychnine. The spirit is added for its preservation. A change was made in the last revision of the *Br. Pharm.* 1898 whereby strychnine hydrochloride is dissolved directly in water containing a little alcohol. This is said to prevent the tendency of the solution to crystallize in cold weather, a fault of the *Br. Ph.* 1885 process.

Dose, from five to ten minims (0.3 to 0.6 Cc.), equal respectively to about the twenty-fourth and the twelfth of a grain (0.0025 to 0.005 Gm.) of the alkaloid.

LIQUOR THYROIDEI. Br.

THYROID SOLUTION

(H'quor thÿ-rö'dë-i)

"A liquid prepared from the fresh and healthy thyroid gland of the sheep." Br.

Thyroid Essence, Thyroid Extract; Schilddrüsen-essenz, Schilddrüsenextrakt, G.

"Remove the external fat and connective tissue from thyroid glands taken from sheep immediately after killing; cut the glands across, and reject any that contain cysts, are hypertrophied, or are otherwise abnormal. Count the healthy glands that remain; slice them and bruise them thoroughly in a mortar; for each entire gland (consisting of two lobes) add *thirty-four minims* or two cubic centimetres of Glycerin, and *thirty-four minims* or two cubic centimetres of a 0.5 per cent. solution of Phenol in Distilled Water; transfer the mixture, well stirred, to a flask, and close the neck with a plug of Cotton Wool; allow it to stand for twenty-four hours; then strain through linen, with strong pressure; add to the strained liquid sufficient of the 0.5 per cent. solution of Phenol to make *one hundred minims* or six cubic centimetres of the Solution for each gland used." Br.

This solution, introduced into the British Pharmacopœia 1898, is intended to represent the activity of the thyroid gland. It is described as a "pinkish turbid liquid, entirely free from any odor of putrescence. It must be freshly prepared, and kept in well-stoppered, sterilized bottles. 100 *minims* or 6 cubic centimetres represent one entire thyroid gland." Br.

For its medicinal properties, see *Thyroideum Siccum*.

Dose, five to fifteen minims (0.3 to 0.9 Cc.).

LIQUOR ZINCI CHLORIDI. U. S., Br.

SOLUTION OF ZINC CHLORIDE

(H'quor zin'ci çhlô'rî-dî)

"An aqueous solution, containing about 50 percent., by weight, of Zinc Chloride [$\text{ZnCl}_2 = 135.26$]." U. S.

Chlorure de Zinc liquide, Soluté de Burnett, Fr.; Flüssiges Chlorzink, Chlorzinklösung, G.

* "Zinc, granulated, *two hundred and forty grammes* [or 8 ounces av., 204 grains]; Hydrochloric Acid, *eight hundred and forty grammes* [or 29 ounces av., 276 grains]; Nitric Acid, *twelve grammes* [or 185 grains]; Precipitated Zinc Carbonate, *twelve grammes* [or 185 grains]; Distilled Water, a *sufficient quantity*, to make about *one thousand grammes* [or 35 ounces av., 120 grains]. To the Zinc, contained in a glass or porcelain vessel, add *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims] of Distilled Water; then gradually add the Hydrochloric Acid, and digest until reaction ceases and the Acid is saturated.

Pour off the solution, add the Nitric Acid, and heat the solution at a temperature not exceeding 115°C . (239°F .), until a portion, if removed and cooled, solidifies. Allow it to cool, and dissolve the solidified mass in a sufficient quantity of Distilled Water to make the product weigh *one thousand grammes* [or 35 ounces av., 120 grains]. Then add the Precipitated Zinc Carbonate, agitate the mixture occasionally during twenty-four hours, and set it aside until it has become clear by subsidence. Finally, separate the clear Solution by decantation, or by means of a siphon." U. S.

"Granulated Zinc, 1 *pound* (Imperial) or 400 grammes; Hydrochloric Acid, 44 *fl. ounces* (Imp. meas.) or 1100 cubic centimetres; Distilled Water, a *sufficient quantity*. Mix the Hydrochloric Acid with *one pint* (Imp. meas.) or 500 cubic centimetres of Distilled Water in a porcelain dish; add the Zinc; apply gentle heat until gas is no longer evolved; boil for half an hour, supplying the water lost by evaporation; allow the product to cool. Test a few drops of the resulting liquid for iron and lead.

If either be present, filter the remainder of the product into a bottle, and add *solution of chlorine* by degrees, with frequent agitation, until the liquid acquires a permanent odor of chlorine; add Zinc Carbonate in small quantities at a time, with renewed agitation, until a brown sediment appears and the whole of the iron or lead is thus precipitated; filter the liquid into a basin, and evaporate to the bulk of *two pints* (Imp. meas.) or one thousand cubic centimetres. If no iron or lead be present, filter the cooled product and evaporate it to *two pints* (Imp. meas.) or one thousand cubic centimetres." Br.

The zinc chloride is made in the usual way, by dissolving zinc in hydrochloric acid. The nitric acid in the U. S. process is added in order that any iron present shall be converted into ferric chloride, from which it is afterwards precipitated by the zinc carbonate. In the older processes the former object was accomplished by the use of solution of chlorinated lime, the latter by chalk. This is a decided improvement, as the use of the chalk as a precipitant introduced into the preparation some calcium chloride, while the zinc carbonate adds only a little zinc chloride in solution. Hydrogen dioxide has been used instead of nitric acid as an oxidizing agent by Besthorn and others. The preparation is completed by bringing it to a certain weight by the addition of distilled water, and by filtration to separate the precipitated iron and any excess of the carbonate. On account of the difficulty of freeing zinc from iron contamination, Francis Hemm proposes the simpler process of making this solution from iron-free zinc oxide; he dissolves 300 Gm. of such zinc oxide in 840 Gm. of hydrochloric acid in a porcelain dish, with the aid of heat, cools, filters, and evaporates the filtrate to 1000 Gm. (*Am. Drug.*, 1900, 199.)

Properties.—As procured by the U. S. P. process, solution of zinc chloride is “a clear, colorless liquid, odorless, having a very astringent, metallic taste, and an acid reaction. Specific gravity: about 1.548 at 25° C. (77° F.). It should conform to the reactions and tests for an aqueous solution of the salt given under *Zinci Chloridum*.” U. S. “A colorless liquid of astringent and sweetish taste. Specific gravity 1.530. It should respond to the tests for zinc and for chlorides. It should not yield any characteristic reaction with the tests for lead, copper, cadmium, arsenium, iron, aluminium, calcium, magnesium, or sulphates.” Br. The British solution contains about 175 grains of zinc in the Imperial fluidounce. The U. S. P. solution does not differ much, containing about 170 grains to the fluidounce (wine measure).

Uses.—This solution is equivalent to Burnett's disinfecting fluid noticed below. It is a powerful disinfectant, and, when applied, duly diluted with water, to cancerous and other offensive ulcers, destroys their fetor so long as the dressings are kept moist with it. The solution is recommended by Gaudriot in *gonorrhœa* in both sexes, as having remarkable remedial powers. For men he uses an injection, composed of from twenty-four to thirty-six drops in four fluidounces of water. A small quantity only is injected about an inch up the urethra, two or three times a day. For women he employs a vaginal suppository, formed of five drops of the solution, half a grain of morphine sulphate, and three drachms of a paste consisting of a drachm and a half of starch, a drachm of mucilage of tragacanth, and half a drachm of sugar. The suppository is introduced every day, or every second day.

Burnett's disinfecting fluid, like the official solution, is an aqueous solution of zinc chloride. It contains 200 grains of zinc in each Imperial fluidounce, and has the sp. gr. 2. It is, therefore, considerably stronger than the Dublin solution. It is so called after Sir William Burnett, who introduced it into use, in 1840, as a powerful deodorizing and disinfecting agent in neutralizing noxious effluvia and in arresting animal and vegetable decomposition. Diluted with water it forms Sir William's patent preservative against the dry-rot. The concurrent testimony of a number of observers shows that it acts as an excellent disinfectant for ships, hospitals, dissecting rooms, water closets, privies, etc. Injected into the blood vessels, it preserves bodies for dissection, without impairing their texture, and is said not to injure the knives employed, but the accuracy of the latter statement is doubtful. The advantage is claimed for it that, while it destroys putrid odors, it has no odor of its own. For preserving anatomical subjects, one part of the disinfecting fluid to eighteen of water will form a solution of the proper strength. For disinfecting operations on a large scale, a pint may be mixed with four gallons of water. Solution of zinc chloride is not used internally.

LIQUORES.

SOLUTIONS

(li-quō'rēs)

Solutés, *Fr.*; Liqueurs, *P. G.*; Lösungen, *G.*; Soluzioni, *It.*; Solución, *Sp.*

The U. S. Pharmacopœia includes in this class of preparations all *aqueous* solutions without sugar in which the substance acted on is wholly soluble in water, excluding those in which the dissolved matter is gaseous or very volatile, as in the *Aquæ*, or *Waters*.

Although several changes were made in the strength of preparations of this class in the U. S. Pharmacopœia of 1880 for the sake of round numbers and to adjust the relative quantity of solid to the solvent, so as to avoid fractions in the percentages, yet it was a question then whether these were advantages sufficient to overbalance the disadvantage of changing the doses of important preparations. Since the important change was made, which makes the powerful solutions contain one per cent. of active ingredient, it would certainly be a serious mistake to alter this proportion in the future. The standard of 1 per cent. for arsenical solutions was adopted by the Conférence Internationale pour l'Unification de la Formule des Médicaments Héroïques in 1902 and will undoubtedly be accepted by all the Pharmacopœias.

In the British Pharmacopœia it has been deemed expedient, in almost all instances in which the substance to be dissolved is an isolated solid body, to make the solutions of uniform strength, without regard to the physiological powers of the medicine, or its ordinary dose. There is a convenience in this plan to the prescriber, in relation to all medicines which habitually present themselves to his mind in the solid state, but to alter the strength of a solution which has been long known, and the dose of which is familiar, in order to make it conform with others, is to run the risk of frequent serious errors for the sake of an idea. The Br. Pharm. 1898 introduced under this head ten concentrated infusions, with the object of affording an easy method of making, through dilution, ordinary infusions. The titles (see *Liquor Calumbæ Concentratus*) are very inappropriate.

LITHII BENZOAS. U. S.

LITHIUM BENZOATE

(lith'ī bĕn'zō-as)

$\text{LiC}_7\text{H}_5\text{O}_2 = 127.11$

“It should contain not less than 98.5 per cent. of pure Lithium Benzoate [$\text{C}_6\text{H}_5\text{COOLi}$], and should be kept in well-stoppered bottles.” U. S.

Lithium Benzolcum; Benzoate de Lithine, *Fr.* *Cod.*; Benzoësäures Lithium, Lithiumbenzoat, *G.*; Benzoato litico, *Sp.*

This salt of lithium is made by decomposing lithium carbonate with benzoic acid. E. B. Shuttleworth (*A. J. P.*, 1875) deviates from the usual method of first making a hot solution of benzoic acid and then adding carbonate until effervescence ceases, by reversing the order. One ounce (av.) of lithium carbonate is put into a dish with nine fluidounces of water, the mixture is heated, and three and a quarter ounces (av.) of benzoic acid in small portions added, until the carbonate is all decomposed and effervescence ceases; the solution is filtered and evaporated to dryness, or crystallized if desired. The yield is three and a half ounces. The advantage of this process is a saving in time and labor in evaporating:

No process is given in the Pharmacopœia.

Properties.—It is officially described as a "light, white powder, or small, shining, crystalline scales; odorless, or of faint benzoin-like odor, and of a cooling, sweetish taste; permanent in the air. Soluble in 3 parts of water, and in 13 parts of alcohol, at 25° C. (77° F.); in 2.5 parts of boiling water, and in 10 parts of boiling alcohol. Its solubility in water is increased by the presence of sodium benzoate, but lessened when alcohol is in the solvent. When heated, the salt fuses; at a higher temperature it chars, emits inflammable vapors having a benzoin-like odor, and finally leaves a residue of lithium carbonate mixed with carbon. This residue imparts a crimson color to a non-luminous flame, and its aqueous solution has an alkaline reaction upon litmus paper. The aqueous solution (1 in 20) of Lithium Benzoate has an alkaline reaction upon litmus, but is neutral to phenolphthalein T.S. The addition of a few drops of ferric chloride T.S. to the above solution will produce a voluminous flesh-colored precipitate of ferric benzoate. If an excess of hydrochloric acid be added to a concentrated aqueous solution of 0.6 Gm. of Lithium Benzoate, a white precipitate of benzoic acid will be formed, which, after collecting upon a filter and thoroughly washing and drying, should respond to the tests of purity given under *Acidum Benzoicum*. If the filtrate and washings from this precipitate be evaporated almost to dryness on a water-bath, in a flat-bottomed flask of 50 Cc. capacity, and 10 Cc. of amyl alcohol (boiling point 132° C.) be added, and the mixture cautiously heated until the lower aqueous layer has evaporated, then, after the addition of 3 drops of hydrochloric acid and boiling for three minutes, the resulting insoluble residue should weigh not more than 0.004 Gm. (limit of other alkalies). The removal of the water from the amyl alcohol mixture is facilitated by passing a current of air through the hot solution. If 1 Gm. of the salt be dissolved in 20 Cc. of water, and the benzoic acid precipitated by the addition of a sufficient quantity of hydrochloric acid, the filtrate should respond to the following tests of purity: The addition

of ammonia water until the solution has an alkaline reaction should produce neither turbidity nor precipitation, either before or after boiling (absence of iron, aluminum, etc.). Another portion of this solution should not respond to the Time-Limit Test for heavy metals (see PART III, Test No. 121). If 0.5 Gm. of Lithium Benzoate be thoroughly mixed with about 1 Gm. of powdered anhydrous ammonium sulphate and cautiously ignited in a porcelain crucible, until of constant weight, the residue should weigh not less than 0.210 Gm., nor more than 0.216 Gm." *U. S.* Curtman stated that much of the lithium benzoate in the market contains not only sodium benzoate, but also hippurate, derived from urine-benzoic acid. This renders it much more soluble in water than the pure salt, and also more soluble in alcohol. The precipitated benzoic acid should melt at 121.4° C.; hippuric acid, if pure, melts at 187.5° C. Hence a high melting point for the separated benzoic acid points to this source of contamination.

Uses.—Lithium benzoate has been highly recommended as a remedy against *gout* (*Ed. M. J.*, Jan. 1875), and has been used to some extent.

Dose, from fifteen to thirty grains (1 to 2 Gm.).

LITHII BROMIDUM. U. S.

LITHIUM BROMIDE

(lith'ī-i brō'mj-dūm)

$\text{LiBr} = 86.34$

"It should contain when well dried not less than 97 percent. of pure Lithium Bromide, and should be kept in well-stoppered bottles." *U. S.*

Lithium Bromatum; Bromure de Lithium, *Fr. Cod.*; Bromlithium, Lithiumbromid, *G.*

This salt was made official in the U. S. P. 1880. Yvon prepares lithium bromide by mixing 37 parts of lithium carbonate, 200 parts of distilled water, and 80 parts of bromine, and passing a current of hydrogen sulphide through the mixture until the color of bromine has disappeared. A slight heat is then applied, to drive off excess of hydrogen sulphide and to agglutinate the sulphur. After filtration the liquor is concentrated and finally crystallized by desiccating it under a bell glass, over sulphuric acid. It may also be obtained by double decomposition. Lithium sulphate is first formed by treating 37 parts of lithium carbonate with 49 parts of monohydrated sulphuric acid diluted with its own volume of water. Then 119 parts of potassium bromide are dissolved in the smallest possible quantity of water. When the two solutions are mixed, an abundant precipitate of potassium sulphate is produced on the addition of a little alcohol. The whole is evaporated to dryness, the operation finished on a water bath, and the residue is treated with alcohol, which removes only lithium bromide

and deposits it again on evaporation. The bromide may then be crystallized from water or kept in solution of known strength.¹ (P. J., Sept. 18, 1876.) No process is given in the Pharmacopœia.

Properties.—It is officially described as “a white, granular salt, odorless, and having a sharp, slightly bitter taste; very deliquescent. Soluble in 0.6 part of water at 25° C. (77° F.), and in 0.3 part of boiling water; very soluble in alcohol; also soluble in ether. At a low red heat the salt fuses, and at a higher heat it is slowly volatilized. It imparts a crimson color to a non-luminous flame. Silver nitrate T.S. produces a yellowish-white precipitate insoluble in nitric acid, and in a moderate excess of ammonia water. The aqueous solution is slightly alkaline to litmus paper. If there be added to 10 Cc. of the aqueous solution of the salt (1 in 20) 1 Cc. of chloroform, followed by chlorine water added cautiously, drop by drop, with constant agitation, the liberated bromine will dissolve in the chloroform, imparting to it a yellow to orange color, free from any violet tint (absence of iodine). If 0.5 Cc. of sodium cobaltic nitrite T.S. be added to 5 Cc. of an aqueous solution of the salt (1 in 20), no precipitate or turbidity should occur within 10 minutes (limit of potassium). If to 0.4 Gm. of Lithium Bromide contained in a flat-bottomed flask of 50 Cc. capacity, an excess of hydrochloric acid be added, and the mixture evaporated almost to dryness on a water-bath, and if 10 Cc. of amyl alcohol (boiling point 132° C.) be added and the mixture cautiously heated until the lower aqueous layer has evaporated, then, upon the addition of 3 drops of hydrochloric acid and boiling for three minutes, the resulting insoluble residue should weigh not more than 0.007 Gm. (limit of other alkalis). The removal of the water from the amyl alcohol mixture is facilitated by passing a current of air through the hot solution. The addition of a slight excess of ammonia water to the aqueous solution of the salt (1 in 20), which has been acidulated with hydrochloric acid, should produce neither turbidity nor precipitation, either before or after boiling (absence of iron, aluminum, etc.). An aqueous solution of the salt (1 in 20) should not respond to the Time-Limit Test for heavy metals (see PART III, Test No. 121). If 1 Gm. of dry Lithium Bromide be dissolved in sufficient distilled water to measure 100 Cc., then 20 Cc. of this solution, to which 2 drops of potassium chromate T.S. are added,

should require not less than 22.5 Cc., nor more than 23.9 Cc., of tenth-normal silver nitrate V.S. to produce a permanent red color.” U. S.

Uses.—Lithium bromide was first brought into notice as a remedy by S. Weir Mitchell, who asserts that its action differs from that of the other bromides only in being more hypnotic. Although careful physiological studies of it are wanting, there is little reason for believing that it differs essentially from other bromides in its influence upon the human organism. It should be administered in dilute aqueous solution. Each drachm of it contains fifty-five grains of bromine, and it therefore exceeds potassium bromide in bromine strength.

Dose, fifteen to thirty grains (1 to 2 Gm.).

LITHII CARBONAS. U. S., Br.

LITHIUM CARBONATE

(lith'īi cār'bō-nās)

$\text{Li}_2\text{CO}_3 = 73.51$

“It should contain not less than 98.5 percent. of pure Lithium Carbonate $[\text{CO}(\text{OLi})_2]$, and should be kept in well-stoppered bottles.” U. S. “Lithium Carbonate, Li_2CO_3 , is obtained from native silicates of lithium.” Br.

Carbonas Lithicus; Carbonate of Lithia; Carbonate de Lithine, *Fr. Cod.*; Carbonate lithique, *Fr.*; Lithium Carbonicum, *P. G.*; Lithiumcarbonat, *Kohlenaures Lithium, G.*; Carbonato di litio, *It.*; Carbonato de litina o litico, *Sp.*

The alkali *lithia*, so far as has yet been ascertained, is rare in nature, for, though extensively diffused, it exists in very small proportion, except in a few scarce minerals. It was discovered by Arfvedson in 1817, in certain minerals from the iron mines of Utö, as *petalite*, *triphane*, and a variety of *tourmaline*. (Berzelius.) It has since been found in other minerals, as *lepidolite*, *spodumene*, *amblygonite*, etc., and in numerous mineral waters, as those of Carlsbad, Pyrmont, Kissingen, Kreuznach, Aix-la-Chapelle, Vichy, etc., in Europe, and the Gettysburg spring in the United States, in which it exists generally as a carbonate or a bicarbonate. By spectrum analysis it has been detected in the waters of the Atlantic and of the Thames, in the ashes of plants grown on a granite soil, and even in milk and human blood. In the mother waters of tartaric acid, in the factories, it has been found in a proportion to justify extraction. It was at one time largely obtained from a *phosphatic triphylite* found in Bavaria, in which it existed as a phosphate, but this source is said to have been exhausted. It is estimated that there are about 55,000 pounds of lithium salts used in the United States each year, of which about one-tenth is imported. The quantity of lithium minerals produced in the United States (California and South Dakota) in 1903 amounted to 1,155 tons, valued at the place of production at \$23,425. There are several methods of extracting lithia from the minerals containing it,

¹ *Lithium Iodide* (LII = 132.8) may be prepared by taking of Iodine 127 parts, iron, in filings, 35 parts, lithium carbonate 38 parts, distilled water 300 parts. Prepare a solution of ferrous iodide, using the whole of the distilled water, filter, add the lithium carbonate to the still warm liquid, and heat gently to promote complete decomposition. The liquid must be slightly alkaline. Filter, wash the precipitated ferrous carbonate, add the washings to the filtrate, evaporate the latter, pour it out to cool and harden, and immediately transfer it into well-dried, glass-stoppered vials. It forms a white salt very soluble in water and alcohol. One gramme of it is entirely precipitated by 1.27 Gm. of silver nitrate. (N. R., July, 1877.)

an account of which may be seen in *Roscoe and Schorlemmer*, vol. ii., Part I, page 158. They contain the alkali in various proportions, from 4.5 per cent. in lepidolite to 11 per cent. in amblygonite. Lithium carbonate is prepared from lepidolite in the following manner. 10 parts of finely powdered lepidolite, 10 parts of barium carbonate, 5 parts of barium sulphate, and 3 parts of potassium sulphate are fused at a very high temperature in a wind furnace. The heavy barium silicate and sulphate sink to the bottom, and a layer of potassium and lithium sulphates is found at the top of the fused mass. These can be extracted by simple lixiviation, and then the carbonate prepared by double decomposition with ammonium carbonate.

Lithia, Li_2O , is the oxide of the metal lithium, and ranks in chemical properties with the fixed alkalis. In the form of hydroxide, LiOH , it is white and translucent; does not deliquesce in the air, but absorbs carbon dioxide, and becomes opaque; is fusible below ignition, but not volatilizable at a white heat; is soluble in water, but less so than potassium or sodium hydroxides; is sparingly soluble in alcohol, and in solution has an acrid alkaline taste, caustic properties, and a strong alkaline reaction. The salts of lithium are generally freely soluble, with the exception of the neutral carbonate and phosphate, the latter of which is nearly insoluble. *Lithium*, which was first obtained by Bunsen and Matthiessen, in 1855, is silver-white, brilliant, softer than lead, ductile, capable of welding, and the lightest known solid. Its sp. gr. is 0.594, melting point 180°C . (356°F .), atomic weight 6.98, and symbol Li . For a method of making lithium for scientific demonstration on the small scale by electrolysis see *Ph. Rev.*, 1899, 264.

Lithium carbonate may be prepared directly from one of the lithia minerals, in the manner already described, or from lithium sulphate or chloride in concentrated solution by adding ammonium carbonate. The precipitated salt should be washed with alcohol and dried.

Properties.—It is “a light, white powder, odorless, and having an alkaline taste; permanent in the air. Soluble in 75 parts of water at 25°C . (77°F .), also in 140 parts of boiling water;¹ much more soluble in water saturated with carbon dioxide; insoluble in alcohol; soluble in diluted acids with active effervescence. At a low red heat the salt fuses; at a higher temperature it loses some of its carbon dioxide, and is partially converted into lithium oxide. Its solution in hydrochloric acid imparts a crimson color to a non-luminous flame. The aqueous solution has an alkaline reaction upon litmus paper. If 1 Gm. of Lithium Carbonate be dis-

solved in 40 Cc. of diluted acetic acid, no insoluble residue should remain. If 1 part of Lithium Carbonate be mixed with 20 parts of water, and hydrochloric acid be added, drop by drop, with agitation until solution takes place, the resulting solution should, after boiling and cooling, respond to the following tests when applied to separate portions: The addition of ammonia water until the solution has an alkaline reaction, should produce neither turbidity nor precipitation, either before or after boiling (absence of *iron, aluminum, etc.*). Another portion of this solution should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If to 0.2 Gm. of Lithium Carbonate contained in a flat-bottomed flask of 50 Cc. capacity a slight excess of hydrochloric acid be added, and the mixture evaporated almost to dryness on a water-bath, and if 10 Cc. of amyl alcohol (boiling point 132°C .) be added and the mixture cautiously heated, until the lower aqueous layer has evaporated, then, upon the addition of 3 drops of hydrochloric acid and boiling for three minutes, the resulting insoluble residue should weigh not more than 0.003 Gm. (limit of *other alkalis*). The removal of the water from the amyl alcohol mixture is facilitated by passing a current of air through the hot solution. If 0.5 Gm. of Lithium Carbonate be dissolved in 20 Cc. of normal sulphuric acid V.S., the resulting solution should require not more than 6.6 Cc. of normal potassium hydroxide V.S. for complete neutralization, methyl-orange T.S. being used as indicator.” *U. S.* “In white powder or in minute crystalline grains, soluble in about 70 parts of cold water, insoluble in alcohol (90 per cent.). Its aqueous solution turns *red litmus paper* blue. It is dissolved with effervescence by *hydrochloric acid*; the solution evaporated to dryness leaves a residue, which communicates a crimson color to flame. This residue redissolved in water yields a precipitate with *solution of sodium phosphate*. 1 gramme of the salt neutralized with *sulphuric acid* and afterwards heated to redness leaves 1.479 grammes of dry lithium sulphate, corresponding to 98.5 per cent. of the pure carbonate. It should yield no characteristic reaction with the tests for lead, copper, arsenium, iron, aluminium, zinc, magnesium, sodium, potassium, ammonium, or chlorides, and only the slightest reactions with the tests for calcium and for sulphates.” *Br.* Its aqueous solution has an alkaline reaction.²

Uses.—Lithium carbonate has the ordinary remedial properties of the alkaline carbonates, over which, however, it possesses advantages, under certain circumstances, which render it a

¹ F. A. Flügelger states that lithium carbonate is less soluble in warm water than in cold water. He recommends as a test of purity that it should require for solution 70 parts or a little more of water at 15°C ., and states further that its solution saturated at 90°C . has the sp. gr. 1.000 at 15°C .; this latter solution contains 1 part of the salt in 111.3 parts of water. (*A. Pharm.*, 1887, p. 508.)

² *Effervescing Lithium Carbonate.*—Take of Citric Acid 40 parts, Sodium Bicarbonate 50 parts, and Lithium Carbonate 10 parts. Powder and mix well, then introduce into a wide flat-bottomed dish, and heat to about 100°C . (212°F .), stirring constantly until the powder becomes granular. Separate the granules of uniform size by means of appropriate sieves, and preserve them in well-stoppered bottles. (See *Lithii Citras Effervescentia*.)

valuable addition to the *materia medica*. In the year 1843, Alexander Ure of London, called attention to the extraordinary solvent power of a solution of lithia for uric acid, with which, unlike the other alkalies, it forms a very soluble salt, and suggested its injection into the bladder, for the solution or disintegration of *uric acid calculi*. In 1857, Garrod of London, gave it internally in cases of *gout* and *gouty diathesis* in reference to the same property, as well as in consideration of its low combining number and consequent extraordinary neutralizing power. From these properties, it is admirably adapted to cases in which it is desirable to eliminate uric acid from the system, and especially to cases of *gout*, in which there is a strong indication to prevent the formation of insoluble salts of uric acid, and their deposition in the bladder, kidneys, or joints, and to favor the solution of such salts when already formed, as in the chalky deposits in the joints and ligamentous tissues of *gouty* patients, consisting chiefly of sodium urate. Garrod has, moreover, found lithium carbonate, in dilute solution, not only to exceed the other alkalies in rendering the urine neutral or alkaline, but also to act powerfully as a diuretic, probably more so than the corresponding salts of potassium and sodium. (*M. T. G.*, March, 1864, 303.)

Dose, five to fifteen grains (0.32 to 1.0 Gm.).

LITHII CITRAS. U. S., Br.

LITHIUM CITRATE

(lith'ī-i cit'rās)

"It should, when carefully dried, contain not less than 98.5 percent. of pure Lithium Citrate [$\text{C}_6\text{H}_4(\text{OH})(\text{COOLi})_3$], and should be kept in well-stoppered bottles." *U. S.* "Lithium Citrate, $\text{C}_6\text{H}_4\text{OH}(\text{COOLi})_3 \cdot 4\text{H}_2\text{O}$, is prepared by saturating citric acid with lithium carbonate." *Br.*

Lithiæ Citras, Lithium Citricum; Citrate of Lithium, Citrate of Lithia; Citrate de Lithine, *Fr.* *Cod.*; Citronensaures Lithium, Lithiumcitrat, *G.*

To saturate the 50 grains of lithium carbonate directed by the British Pharm. (1885) 90.54 grains of the crystallized acid will be required, so that there is a slight deficiency on the part of the acid, whereas it should be in slight excess, and, according to Squire, 100 grains of the acid should be used instead of 90 grains. (See also *P. J.*, Sept. 11, 1875.) This proportion was employed in the *U. S. Pharmacopœia* process of 1870. See foot-note.¹

¹"Take of Carbonate of Lithium one hundred grains; Citric Acid, in crystals, two hundred grains; Distilled Water two fluidounces. Dissolve the Citric Acid in the water gently heated, and to the solution gradually add the Carbonate of Lithium until perfectly dissolved, heating the solution so long as effervescence is produced. Evaporate, by means of a steam- or sand-bath, to a viscid consistence, dry the residue in an oven, at a temperature of about 240°, then rapidly pulverize it, and preserve the powder in a well-stoppered bottle." *U. S.* 1870.

C. Umney (*P. J.*, Sept. 11, 1875) advocates the use of the crystallized salt in place of that made by either of the former official processes. He obtained it by setting aside a solution of the sp. gr. 1.230, when a salt crystallized out having the formula $\text{Li}_3\text{C}_6\text{H}_5\text{O}_7 \cdot 4\text{H}_2\text{O}$; it is described as definite and reliable as found in commerce, and "not deliquescent." (See also *P. J.*, 1883, p. 783.)

Properties.—Lithium citrate is in the form of "a white powder, or colorless crystals, odorless, and having a cooling, faintly alkaline taste; deliquescent on exposure to moist air. Soluble in about 2 parts of water at 25° C. (77° F.), and in 1.5 parts of boiling water; almost insoluble in alcohol or ether. At a red heat the salt chars, emits inflammable vapors having a pungent odor, and finally leaves a black residue of lithium carbonate mixed with carbon. It imparts a crimson color to a non-luminous flame. The aqueous solution is neutral to litmus paper, and should not redden phenolphthalein T.S. If an aqueous solution of Lithium Citrate (1 in 20) be boiled with an equal volume of calcium chloride T.S., a white precipitate will form. If the residue obtained by igniting 0.2 Gm. of the salt at a red heat be treated with a slight excess of diluted hydrochloric acid, and the filtrate and washings evaporated almost to dryness on a water-bath, in a flat-bottomed flask of 50 Cc. capacity, and if 10 Cc. of amyl alcohol (boiling point 132° C.) be added, and the mixture cautiously heated until the lower aqueous layer has evaporated, then, upon the addition of 3 drops of hydrochloric acid and boiling for three minutes, the resulting insoluble residue should weigh not more than 0.002 Gm. (limit of *other alkalies*). The removal of the water from the amyl alcohol mixture is facilitated by passing a current of air through the hot solution. The solution of the salt (1 in 20) acidulated with hydrochloric acid should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If 0.5 Gm. of anhydrous Lithium Citrate be cautiously ignited in a porcelain crucible, and if, after cooling, the residue be moistened with a few drops each of nitric and sulphuric acids and again cautiously ignited, repeating the operation until the residue becomes white and of constant weight, then the residue of lithium sulphate should weigh not less than 0.387 Gm., nor more than 0.394 Gm. The residue of lithium sulphate resulting from the above ignition, after being dissolved in 10 Cc. of boiling water and acidified with hydrochloric acid, should, upon the addition of ammonia water until the solution has an alkaline reaction, not become turbid or form a precipitate, either before or after boiling (absence of *iron, aluminum, etc.*)." *U. S.* "2 grammes of the salt dried at 212° F. (100° C.) should lose about 0.38 gramme; at 240° F. (115.5° C.) an additional 0.13 gramme; and, when burned at a low red heat with a free access of air, should leave 0.77 gramme of white residue, correspond-

ing to 98.5 per cent. of the pure citrate. It should be free from the impurities mentioned under 'Lithii Carbonas.' Br. That the salt is a citrate will be shown by its solution becoming turbid when boiled with lime water, but clear again on cooling.

Uses.—These are essentially the same as those of the carbonate, as the citric acid is burnt up in the system and a lithium carbonate formed, which is finally eliminated by the kidneys. While thus acting like the carbonate, it has the advantage over that salt of having a less disagreeable taste and of being less disposed to irritate the stomach,—the same advantages that, in many instances, potassium citrate has over the carbonate of that alkali.

Dose, from ten to thirty grains (0.65 to 2.0 Gm.).

Off. Prep.—Lithii Citras Effervescens, U. S., Br.

LITHII CITRAS EFFERVESCENS.

U. S., Br.

EFFERVESCENT LITHIUM CITRATE

(lith'ī-i citrās ēf-fer-vēs'cens)

Limonađe sèche au Citrate de Lithine, Fr.; Brause-lithiumcitrat, G.

* "Lithium Citrate, fifty grammes [or 1 ounce av., 334 grains]; Sodium Bicarbonate, dried and powdered, five hundred and seventy grammes [or 20 ounces av., 46 grains]; Tartaric Acid, dried and powdered, three hundred grammes [or 10 ounces av., 255 grains]; Citric Acid, uneffloresced crystals, one hundred and ninety-five grammes [or 6 ounces av., 384 grains], to make about one thousand grammes [or 35 ounces, 120 grains]. Powder the Citric Acid and mix it intimately with the Lithium Citrate and Tartaric Acid, then thoroughly incorporate the Sodium Bicarbonate. Place the mixed powders on a plate of glass or in a suitable dish, in an oven heated between 93° and 104° C. (199.4° and 219.2° F.). When the mixture, by the aid of careful manipulation with a wooden spatula, has acquired a moist consistence, rub it through a No. 6 tinned-iron sieve, and dry the granules at a temperature not exceeding 54° C. (129.2° F.). Keep the product in well-stoppered bottles." U. S.

"Sodium Bicarbonate, in powder, 58 ounces (Imperial) or 580 grammes; Tartaric Acid, in powder, 31 ounces (Imp.) or 310 grammes; Citric Acid, in powder, 21 ounces (Imp.) or 210 grammes; Lithium Citrate, 5 ounces (Imp.) or 50 grammes. Mix the Lithium Citrate with the Citric Acid, then add the Tartaric Acid, and, lastly, the Sodium Bicarbonate, triturating thoroughly. Place the whole in a dish or pan of suitable form heated to between 200° and 220° F. (93.3° and 104.4° C.). When the mixture, by the aid of careful manipulation, has assumed a granular character, separate it, by means of suitable sieves, into granules of uniform and convenient size. Dry the granules at

a temperature not exceeding 130° F. (54.4° C.). The product should weigh about 100 ounces (Imp.) or 1000 grammes." Br.

This process was improved in the U. S. P. (8th Rev.) by omitting the sugar (which tends to darken the product), and by making a granular salt; the U. S. P. 1890 product was in the form of a dry powder.

Uses.—This effervescent salt forms an agreeable method of administering lithia; its medicinal properties are those of lithium citrate,

Dose, two drachms (7.7 Gm.), given in solution.

LITHII SALICYLAS. U. S.

LITHIUM SALICYLATE

(lith'ī-i sāl-i-cy'lās)

LiC₇H₅O₃ = 142.99

"It should contain not less than 98.5 percent. of pure Lithium Salicylate [C₆H₄(OH)COOLi], and should be kept in well-stoppered bottles." U. S.

Salicylate de Lithine, Fr. Cod.; Lithium salicylicum, P. G.; Lithiumsalicylat, G.; Salicillato de litina, Sp.

No process is given in the Pharmacopœia for this official salt. It may be prepared by adding to a mixture of eleven parts of salicylic acid and three parts of lithium carbonate twenty-five parts of water, and heating until effervescence ceases, filtering and evaporating. It may be obtained in crystals but is usually seen in the form of a granular powder.

Properties.—It is officially described as "a white or grayish-white powder, odorless, and having a sweetish taste; deliquescent in a moist atmosphere. Very soluble in water and in alcohol. When heated, the salt is decomposed, emitting the odor of phenol, and finally leaving a residue of lithium carbonate and carbon. It imparts a crimson color to a non-luminous flame. The aqueous solution slightly reddens blue litmus paper. The aqueous solution should be colorless (absence of iron and organic coloring matters), and should not effervesce upon the addition of diluted acids (absence of carbonate). If copper sulphate T.S. be added to an aqueous solution of the salt (1 in 20), the mixture should have a bright green color. If a few drops of ferric chloride T.S. be added to an excess of a concentrated aqueous solution of Lithium Salicylate (1 in 4), a deep red color will be produced, which, after the liquid is largely diluted and mixed with more ferric chloride T.S., will change to a deep bluish-violet tint. Upon adding to 0.5 Gm. of the salt, in a test-tube, about 1 Cc. of concentrated sulphuric acid, and cautiously, drop by drop, about 1 Cc. of methyl alcohol, then, on heating the mixture to boiling, the odor of oil of gaultheria will be evolved. If an excess of hydrochloric acid be added to a concentrated aqueous solution of 0.7 Gm. of Lithium Salicylate, a voluminous precipitate of salicylic acid will be formed, which, after

collecting upon a filter and thoroughly washing and drying, should conform to the reactions and tests given under *Acidum Salicylicum*. If the filtrate and washings from this precipitate be evaporated almost to dryness on a water-bath, in a flat-bottomed flask of 50 Cc. capacity, and 10 Cc. of amyl alcohol (boiling point 132° C.) added, and if, after cautiously heating until the lower aqueous layer has evaporated, 3 drops of hydrochloric acid be added and the solution boiled for three minutes, the resulting insoluble residue should weigh not more than 0.005 Gm. (limit of *other alkalies*). The removal of the water from the amyl alcohol mixture is facilitated by passing a current of air through the hot solution. If 1 Gm. of the salt be dissolved in 20 Cc. of water, and the salicylic acid precipitated by the addition of a sufficient quantity of hydrochloric acid, the filtrate should respond to the following tests of purity: The addition of ammonia water until the solution has an alkaline reaction should produce neither turbidity nor precipitation, either before or after boiling (absence of *iron, aluminum, etc.*). Another portion of this solution should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). If 0.5 Gm. of dry Lithium Salicylate be thoroughly mixed with about 1 Gm. of powdered anhydrous ammonium sulphate, and cautiously ignited in a porcelain crucible until of constant weight, the residue should weigh not less than 0.188 Gm., nor more than 0.192 Gm." *U. S.*

Uses.—This salt has been introduced into the U. S. Pharmacopoeia as a remedy in *gout* and *rheumatism*, uniting the virtues of salicylic acid and of lithium. It will probably be found efficient, and has the great advantage over salicylic acid of being freely soluble in water and much less irritant to the stomach. One drachm contains the equivalent of about 57 grains of salicylic acid and 3 grains of lithium.

Dose, twenty to forty grains (1.3 to 2.6 Gm.).

LOBELIA. U. S., Br.

LOBELIA

(10-bē'li-ā)

"The dried leaves and tops of *Lobelia inflata* Linné (Fam. *Campanulaceæ*), collected after a portion of the capsules have become inflated." *U. S.* "The dried flowering herb of *Lobelia inflata*, Linn." *Br.*

Indian or Wild Tobacco, Asthma-weed, Puke-weed, Bladder Pod, Eyebright; Lobellie enflee, *Fr. Cod.*; Herba Lobellie, *P. G.*; Lobellenkraut, *G.*; Lobelia, *It.*

Lobelia inflata, L., *Sp. Pl.* (1753) 931; Willd., *Sp. Plant.* i. 946; Bigelow, *Am. Med. Bot.*, i. 177; Barton, *Med. Bot.* i. 181; Carson, *Illust. of Med. Bot.*, i. 60, pl. 51; B. & T. 162.—This species of *Lobelia*, often called *Indian tobacco*, is an annual or biennial indigenous plant, usually a foot or more in height, with a fibrous root, and a solitary, erect, angular, very hairy stem, much branched about midway, but rising

considerably above the summits of the highest branches. The leaves are scattered, or alternate, petiolate, the upper sessile, ovate, or oblong, about two inches (5 Cm.) long, irregularly toothed, pubescent, pale green. The flowers are numerous, small, disposed in leafy terminal racemes, and upon short axillary footstalks. The calyx is five-toothed and much inflated in fruit. The corolla, which is of a delicate blue, has a labiate border, with the upper lip divided into two, the lower into three segments. The united anthers are curved, and enclose the stigma. The fruit is an oval, striated, inflated capsule, crowned with the persistent calyx, and containing, in two cells, numerous very small, oblong, reticulated brown seeds.¹ The transverse section of the stem exhibits laticiferous vessels in the bast.

*Lobelia inflata*² is a very common weed, growing on the roadsides and in neglected fields throughout the Eastern United States and Canada. Its flowers begin to appear towards the end of July, and continue to expand in succession until the occurrence of frost. All parts of it are medicinal, but, according to Eberle, the root and inflated capsules are most powerful. The plant should be collected in August or September, when the capsules are numerous, and should be carefully dried. It may be kept whole or in powder. As found in commerce, it is often in oblong compressed cakes, prepared by the Shakers or the herb dealers.

Dried lobelia has a slightly irritating odor, and when chewed, though at first without much taste, soon produces a burning acrid impression upon the posterior parts of the tongue and palate, very closely resembling that occasioned by tobacco, and attended in like manner with a flow of saliva and a nauseating effect. "Leaves alternate, the lower short-petioled, the upper sessile, ovate or oblong, 4 to 9 Cm. long; irregularly serrate-denticulate, the divisions with a yellowish-brown, gland-like apex; pale green, pubescent; stems coarsely angled, often purplish, hairy, terminating in long racemes of small short-pedicelled flowers having an adherent 5-toothed calyx and a small tubular corolla, cleft to the base on the upper side, the one-sided limb 5-lobed, and pale blue in the fresh

¹ In case of poisoning by lobelia, the seeds may be recognized by the following microscopic characters. (Fred. Curtis, *Lond. Med. Gaz.*, July, 1851.) They are almond-shaped, about 1-30th of an inch long by 1-75th broad, puce-colored, regularly marked with longitudinal ridges and furrows, and cross ridges generally at right angles with the former, so that the surface presents the appearance of basket work. No other seeds could be mistaken for them, except those of *Lobelia cardinalis*, which, however, are larger, coarser, of a lighter color, and with the superficial rectangular checkering less distinct.

² Two other North American species of lobelia have been used in medicine, but appear to be of very little value.—*L. cardinalis*, or cardinal flower, as an anthelmintic; *L. syphilitica*, as an antisyphilitic. (See W. P. C. Barton's *Medical Botany*.) V. Rosen has found in the *L. nicotianefolia*, which grows in the mountain ranges of Ceylon and the Madras Peninsula, two alkaloids,—one liquid and identical with lobeline, the other a crystalline solid. He believes, as the result of some physiological experiments, that the plant has the same properties as those of *L. inflata*. (*P. J.*, 1886, p. 838.)

state, the five stamens united; capsule inflated, 2-celled, containing numerous minute brownish, ellipsoidal, coarsely reticulate seeds; odor slight, irritating; taste strongly acrid." *U. S.* The powder is greenish. The plant yields its virtues readily to water and alcohol. Water distilled from it has its odor without its acrimony. Procter found the plant to contain an odorous volatile principle, probably volatile oil; a peculiar alkaline principle, named lobeline; a peculiar acid, first noticed as distinct by Pereira, called *lobelic acid*; besides gum, resin, chlorophyll, fixed oil, lignin, salts of lime and potassium with ferric oxide. The seeds contain at least twice as much of lobeline, in proportion, as the whole plant, which yielded only one part in five hundred. They contain also 30 per cent. of a nearly colorless fixed oil having the drying property in an extraordinary degree. *Lobeline* was obtained by Procter by the following process. The seeds were treated with alcohol acidulated with acetic acid, until deprived of acrimony, and the tincture was evaporated; the resulting extract was triturated with magnesia and water, and, after repeated agitation for several hours, the liquor, holding lobeline in solution, was filtered; this was then shaken repeatedly with ether until no longer acrid, and the ethereal solution, having been decanted, was allowed to evaporate spontaneously. The residue, which was reddish brown and of the consistence of honey, was deprived of coloring matter by dissolving it in water, adding a slight excess of sulphuric acid, boiling with animal charcoal, saturating with magnesia, filtering, agitating with ether until this fluid had deprived the water of acrimony, and finally decanting and allowing the ether to evaporate. Thus obtained, *lobeline* is a yellowish liquid, lighter than water, of a somewhat aromatic odor, and a very persistent, acrid taste. It is soluble in water, but much more copiously in alcohol and ether, and the latter fluid readily removes it from its aqueous solution. It has an alkaline reaction, and forms soluble and crystallizable salts with sulphuric, nitric, and hydrochloric acids, and a very soluble but not crystallizable salt with acetic acid. It forms an insoluble compound with tannic acid, which instantly precipitates it from its solution. By a boiling heat it is entirely decomposed, losing all its acrimony, but when combined with acids it may be subjected to ebullition with water without change. (*A. J. P.*, ix. 105, xiii. 1; see also a paper by W. D. Richardson, Jr., *A. J. P.*, 1872, p. 293.)¹ Paschke and Smita (*M. Chem.*, xi. p. 131) obtained the alkaloid as a viscous oil with an odor resembling at once that of honey and that of tobacco. Siebert has also obtained both from the herb and seeds of lobelia a pale-yellow alkaline syrup, the crys-

tallized hydrochloride and chloroplatinate of which indicated the formula $C_{12}H_{13}NO_2$ for the free alkaloid. Enders has also isolated the acrid substance of the drug, and gives to it the name *lobelacrin*. It is obtained in warty tufts of a brown color, soluble in ether and chloroform, but only slightly in water. It is decomposed by boiling with diluted acids or alkalis into sugar and lobelic acid. Lewis (*P. J.* [3], 10, p. 56) considers lobelacrin as only a mixture of lobeline lobelate with free lobelic acid. (*Pharmacographia*, 2d ed., 400.) Lloyd considers the lobelacrin of Enders to be a mixture of inflatin, resin, lobeline, and the fixed oil which lobelia seed contains in the proportion of about 30 per cent. S. Colhoun of Philadelphia, was the first to announce the existence of a peculiar principle in lobelia, capable of forming salts with the acids, but he did not obtain it in an isolated state. An important inference from the effects of heat upon lobeline is that, in preparing lobelia for use, the plant should never be heated in connection with a salifiable base. J. U. Lloyd isolated from lobelia a crystalline substance, melting at 225° C., which had been observed previously by Procter. Lloyd named it *inflatin*; it is colorless, tasteless, and odorless, insoluble in water or glycerin, soluble in carbon disulphide, benzene, chloroform, ether, and least soluble in alcohol. It is a neutral principle, and appears to have no therapeutic value. (*Ph. Rund.*, 1887, 32.)

Uses.—Lobelia is said to have been used as a medicine by the aborigines of America, but was first brought into general professional notice by Cutler of Massachusetts. The leaves or capsules, chewed for a short time, occasion giddiness, headache, general tremors, and ultimately nausea and vomiting. When swallowed in the full dose, the medicine produces speedy and severe vomiting, attended with continued and distressing nausea, copious sweating, and great general relaxation. When toxic doses are taken, these symptoms are very severe, and have added to them burning pain in the fauces or oesophagus, progressive failure of voluntary motion, rapid, feeble pulse, fall of temperature, and finally collapse with stupor or coma; in some cases convulsions precede death. Death has often resulted from its empirical use. Its poisonous effects are most likely to occur when, as sometimes happens, it is not rejected by vomiting. The experiments of I. Ott upon the lower animals show that the poison causes paralysis of the motor nerve trunks, of the peripheral vagi, and probably also of the vasomotor centres. Death seems to occur from failure of respiration, due, in part at least, to the condition of the motor nerves.

As an emetic, lobelia should never be used; at present it is rarely employed at all except in *spasmodic asthma*, the paroxysms of which it often greatly mitigates, and sometimes wholly relieves, even when not given in doses large enough to produce vomiting. It has been used also in *catarrh*, *croup*, *pertussis*, and other

¹ William Bastick of London, published (*P. J.*, Dec. 1850) an article on lobeline, apparently in entire ignorance of the previous work of Procter. His process does not differ essentially from that above given. In one magnesia is used to decompose the native salt of lobeline, in the other lime, the caustic alkalis not being applicable to the purpose, as they decompose this alkaloid with great facility.

laryngeal and pectoral affections, but is chiefly valuable where there is *bronchial spasm*; it must always be employed with caution. The tincture affords the most eligible mode of administration; in asthmatic cases it may be given in doses of fifteen minims (0.9 Cc.) every hour until an effect is produced. The fluidextract and the tincture are official. The process for the vinegar, which was dropped by the U. S. Pharmacopœia of 1890, will be found in the foot-note.¹ Nunes (*T. G.*, 1889) asserts that he has used lobeline in a number of cases of *asthma* with most excellent results in doses of from three-fourths of a grain to six grains a day; but it can scarcely be doubted that he had a very impure alkaloid, and that such doses of a pure sample would be highly dangerous.

Dose, antispasmodic, five grains (0.32 Gm.).

¹ *Acetum Lobeliai*, *U. S.* 1880. *Vinegar of Lobelia*. (*Vinaigre de Lobélie enflée*, *Fr.*; *Lobelinensis*, *G.*) "Lobelia, in No. 30 powder, ten parts [or one and three-fourths ounces av.]; Diluted Acetic Acid, a sufficient quantity, to make one hundred parts [or one pint]. Moisten the powder with five parts [or one fluidounce] of Diluted Acetic Acid, pack it firmly in a conical glass percolator, and gradually pour Diluted Acetic Acid upon it until one hundred parts [or one pint] of filtered liquid are obtained." *U. S.* *Vinegar of Lobelia* may also be prepared by macerating the powder in one pint of Diluted Acetic Acid for seven days, expressing the liquid, and filtering through paper. This is an active preparation of lobelia. *Dose*, as an expectorant for an adult, from thirty minims to a fluidrachm (1.8 to 3.75 Cc.). In the paroxysm of spasmodic asthma one fluidrachm (3.75 Cc.) may be given every two or three hours until relief is obtained.

¹ J. S. Ward found, as the result of an examination, four samples of lupulin, which fairly represent the commercial article, to yield 54.24, 41.49, 40.04, and 39.41 per cent. of extractive soluble in ether, and to yield 27.01, 29.10, 30.86, and 31.42 per cent. of ash. The samples were all gritty. (*P. J.*, 1886, 656.)

LYCOPODIUM. U. S.

LYCOPODIUM

(lŷ-cq-pō'dī-ŭm)

"The spores of *Lycopodium clavatum* Linné or of other species of *Lycopodium* (Fam. *Lycopodiaceæ*)." U. S.

Semen Lycopodii, Pulvis Lycopodii, Sulphur Vegetabile; Vegetable Sulphur; Lycopode, *Fr. Cod.*; Soufre végétal, *Fr.*; Lycopodium, *P. G.*; Bärlapp-samen, Streupulver, Hexenmehl, Blitzpulver, *G.*; Lycopodio, *It.*, *Sp.*

Lycopodium clavatum, Linn., *Sp. Plant.* (1753) 1101; *B. & T.* 299.—This plant, commonly called *club moss*, has a trailing, branching stem, several feet long, and thickly beset with linear-lanceolate, flat, ribless, smooth, partly serrate leaves with a capillary point, curved upward, and of a deep green color. The fructification is in terminal spikes, single or in pairs, with crowded ovate, entire, pointed scales, bearing in the axil a transversely oval sporangium which splits nearly to the base and contains the narrow reticulate spores. The plant is a native of Europe, Asia, and America.

The spores are collected in Switzerland and Germany. *Lycopodium* is "a fine, pale yellowish, very mobile powder, nearly inodorous and tasteless, floating upon water and not wetted by it, but sinking on being boiled with it, and burning with a quick flash when thrown into a flame. Spores tetrahedral with one convex side, the surface being delicately reticulated, from 0.025 to 0.040 Mm. in diameter. The microscope should show no pollen or starch grains or particles of sand. The ash remaining upon ignition should not exceed 5 percent." U. S. Bucholz in 1807 pointed out the existence of a fixed oil. Flückiger, however, by thoroughly comminuting the spores of *lycopodium* with sand, obtained 47 per cent. of a bland oil of bright yellow color and sp. gr. 0.925, which does not congeal even at -15° C. (5° F.). A. Barkowski obtained from the spores of *Lycopodium clavatum* 48.5 per cent. of a neutral non-drying oil, very similar to almond oil. This oil contains 2 per cent. of a fatty acid called *lycopodic acid* ($C_{18}H_{36}O_4$), 80 per cent. of oleic acid, a minute quantity of a vegetable cholesterin similar to that obtained by Hesse from Calabar beans, 8.2 per cent. of glycerin and 3 per cent. of arachidic, palmitic and stearic acids. The lycopodic acid crystallizes in silky needles, it is doubly refracting like quartz, and appears to be isomeric with dioxystearic acid. (*D. C.*, 1891, 155.) Stenhouse found volatile bases to be present in very small amount. The ash amounts to 4 per cent. It contains alumina and 1 per cent. of phosphoric acid, and is not alkaline. (*Pharmacographia*, 2d ed., 732.) *Lycopodium* is often adulterated with the pollen of the pines and firs, and sometimes with tale and starch. In Nashville, Tenn., a specimen came into the possession of Benj. Lillard which was found to contain one-

half of its bulk of dextrin. (*Ch. Ph.*, Sept. 1873.) Folleto recommends two reactions to detect pollen: one by adding to a syrupy solution of zinc chloride, potassium iodide and iodine to saturation; the pollen is colored yellow by this reagent, *lycopodium* is not colored; the other reagent is methyl-green, which colors pollen green, but does not color *lycopodium*. (*Ph. Centralh.*, 1896, 527.)

Uses.—*Lycopodium* is used as an absorbent application to *excoriated surfaces*, especially those which occur in the folds of the skin in infants. In pharmacy it answers the purpose of facilitating the rolling of the pilular mass, and of preventing the adhesion of the pills when formed. The moss itself has been esteemed diuretic and antispasmodic; its decoction has been employed in *rheumatism, diseases of the lungs and kidneys*, and in the removal of *plica Polonica*, but it has fallen into complete desuetude.

MAGNESII CARBONAS. U. S. (Br.)

MAGNESIUM CARBONATE

(măg-nē'sī-i cār'bq-nās)

Approximately $(MgCO_3)_4$. $Mg(OH)_2 + 5H_2O = 482.26$

"Magnesium Carbonate [$(CO_3)_2Mg$] $_4$. $Mg(OH)_2 + 5H_2O$ should yield, upon ignition, not less than 40 percent. of residue, of which not less than 96 percent. should consist of pure magnesium oxide." U. S.

Magnesii Carbonas Levis, Light Magnesium Carbonate, *Br.*; *Magnesii Carbonas Ponderosus*, Heavy Magnesium Carbonate, *Br.*; Magnesia Hydrico-carbonica, Carbonas Magnesicus, Magnesia Alba, Magnesiæ Carbonas, Carbonate of Magnesia; Carbonate de Magnésie officinal, *Fr. G.*; Magnesiumcarbonat, Kohlensaure Magnesia, Wesse Magnesia, *G.*; Idrocarbonato di magnesio, Carbonato di Magnesia, *It.*; Carbonato Magnesico, Magnesia bianca, *Sp.*

In the U. S. P. (8th Rev.) magnesium carbonate is official under one name "*Magnesii Carbonas*;" this corresponds nearly with "*Magnesii Carbonas Levis*" of the British Pharmacopœia.

Magnesium Carbonate sometimes occurs as a native mineral known as *magnesite*, the best deposits of which are those of the Grecian Archipelago, though a common variety is found in Chester Co., Pa. That which is sold in commerce is prepared on a large scale by the manufacturer. In the British Pharmacopœia directions are given for preparing it in two forms: that of *Magnesii Carbonas Levis*, or Light Magnesium Carbonate; and that of *Magnesii Carbonas Ponderosus*, or Heavy Magnesium Carbonate. The following are the directions:

1. *MAGNESII CARBONAS LEVIS*. *Light Magnesium Carbonate*, *Br.*—"This preparation, $3(MgCO_3)_2 \cdot Mg(OH)_2 \cdot 4H_2O$, may be obtained by the following process. Magnesium Sulphate, 10 ounces (Imperial) or 125 grammes;

Sodium Carbonate, 12 ounces (Imp.) or 150 grammes; Distilled Water, a sufficient quantity. Dissolve the Magnesium Sulphate and the Sodium Carbonate each in half a gallon (Imp. meas.) or one litre of cold Distilled Water; mix the two solutions; boil the mixture for fifteen minutes; transfer the precipitate to a calico filter; pour upon it boiling Distilled Water until the washings are free from sulphates; dry at a temperature not exceeding 212° F. (100° C.)." *Br.* The resulting carbonate is characterized in the British Pharmacopœia as "a very light powder, which, when examined under the microscope, is found to consist of amorphous particles with numerous slender prisms intermixed. The other characters and tests are the same as those of Heavy Magnesium Carbonate." *Br.*

2. MAGNESII CARBONAS PONDEROSUS. *Heavy Magnesium Carbonate.* *Br.*—"This preparation, $3(\text{MgCO}_3), \text{Mg}(\text{HO})_2, 4\text{H}_2\text{O}$, may be obtained by the following process. Magnesium Sulphate, 10 ounces (Imperial) or 125 grammes; Sodium Carbonate, 12 ounces (Imp.) or 150 grammes; Distilled Water, boiling, a sufficient quantity. Dissolve the Magnesium Sulphate and the Sodium Carbonate each in a pint (Imp. meas.) or two hundred and fifty cubic centimetres of the Distilled Water; mix the solutions, and evaporate to dryness; digest the residue for half an hour with two pints (Imp. meas.) or five hundred cubic centimetres of the Distilled Water, and having collected the insoluble matter on a calico filter, wash it repeatedly with the Distilled Water until the washings are free from sulphates; dry the product at a temperature not exceeding 212° F. (100° C.)." *Br.*

This is essentially the old process of the Dublin College, and yields a product which is characterized in the British Pharmacopœia as "A white granular powder, which dissolves readily, with effervescence, in the diluted mineral acids, the solutions affording the reactions characteristic of magnesium. 5 grammes calcined at a red heat should be reduced to 2.1 grammes. It should yield no characteristic reaction with the tests for iron, aluminium, or calcium, and only the slightest reactions with the tests for chlorides or sulphates." *Br.*

Potassium carbonate is less desirable than sodium carbonate for the preparation of magnesium carbonate. It is difficult to separate the last portions of potassium sulphate from the precipitate, and potassium carbonate usually contains silica, which is thrown down with the magnesia. The consequence is that, when prepared with that salt, magnesium carbonate is liable to be gritty to the touch and to have a saline taste. The following method is said to be pursued by some of the best manufacturers. To a saturated solution of 100 parts of magnesium sulphate, a solution of 125 parts of crystallized sodium carbonate is gradually added, the solutions being constantly stirred. The mixture is heated to ebullition, to complete

the precipitation of the magnesia, which is then washed with tepid and finally with cold water, until the washings no longer give a precipitate with barium salts. When sufficiently washed, the carbonate is allowed to drain for one or two days on large linen filters, and is then placed in wooden moulds with a porous bottom of brick or gypsum, and subjected to pressure in order to give it a square and compact form. According to Otto and Gabler, very pure magnesium carbonate is made at Naunheim, Germany. Pattinson's process is used. It depends upon the fact that, on treating calcined dolomite, in the presence of water, with carbon dioxide under pressure, the magnesia dissolves as bicarbonate before any of the accompanying lime enters in solution. The calcined and finely powdered mineral is introduced, together with water, into a cylinder with a horizontal axis, and, while it is being kept in constant motion by a stirring apparatus, carbon dioxide, under a pressure of five to six atmospheres, is forced into it. The resulting solution of magnesium bicarbonate, which is perfectly free from lime, if the process has been properly managed, is then transferred to a vertical cylinder, where it is heated with steam, whereby magnesium carbonate is separated, which is collected, formed into prismatic pieces, and dried. The carbon dioxide required issues from the earth immediately outside of the factory, and the dolomite is furnished by the quarries of May and Urban, near Dietz and Steelen on the Lahn. (*A. Pharm.*, Aug. 1880; *N. R.*, Sept. 1881.) J. G. Ferrier criticized the processes for making the carbonates by the British Pharmacopœia; he stated that there was a conspicuous want of uniformity in the results obtained. (*P. J.*, 1904, 586.)

The density of magnesium carbonate is said to depend upon the strength of the solutions from which it is first precipitated, and its fineness and softness to the touch, upon the use of sodium carbonate in its preparation. Much of the magnesium carbonate formerly used in this country was imported from England and Ireland, but that now consumed in the United States is chiefly a home product. The Keasbey & Mattison Company, who are the largest manufacturers of carbonate at the present time, use the process of decomposing calcined dolomite by forcing carbon dioxide into its aqueous mixture, and heating this to precipitate the carbonate. When made from bittern, magnesium carbonate is contaminated with calcium carbonate, salts of lime being contained in sea water, and when it is prepared from magnesite, or from magnesian schist, iron is almost always present. The only way in which these impurities can be avoided is to prepare pure magnesium sulphate by repeated crystallization, and to use a pure sodium carbonate. It is also necessary that the water with which the precipitate is washed should be free from earthy salts, which would be decomposed and contaminate the magnesia. Kippenberger pre-

pares crystallized magnesium carbonate by shaking *freshly* precipitated magnesium carbonate with a solution of potassium bicarbonate at the ordinary temperature; much of the magnesium carbonate dissolves and crystallizes out of the filtered solution upon standing for a day. Sodium bicarbonate may be used instead of the potassium salt, but the crystals are smaller. (*Zeit. Anorg. Chem.*, 1894, 177.)

Properties.—Magnesium carbonate is inodorous, nearly insipid, perfectly white, smooth to the touch, and nearly insoluble in water, requiring 2493 parts of cold and 9000 parts of hot water for solution. It is decomposed by strong heat, by all the acids, by potassium, sodium, calcium, barium and strontium hydroxides, and by acidulous and metallic salts. It is officially described as in "light, white, friable masses, or a bulky, white powder, without odor, and having a slightly earthy taste; permanent in the air. Practically insoluble in water, to which, however, it imparts a slightly alkaline reaction; insoluble in alcohol, but soluble in dilute acids with effervescence. When strongly heated, the salt loses water and carbon dioxide, and is converted into magnesium oxide. A filtered solution of the salt in diluted sulphuric acid, when mixed with ammonium chloride T.S. and an excess of ammonia water, yields with sodium phosphate T.S., a white crystalline precipitate." *U. S.* Pereira states that the *light carbonate*, when examined with the microscope, is seen to consist of an amorphous powder, more or less intermingled with slender prismatic crystals, which appear as if they were eroded or efflorescent; the *heavy carbonate* consists of granules of various sizes, without any traces of the prismatic crystals observed in the former variety.

A solution in carbonic acid water, prepared by passing carbon dioxide into a reservoir containing magnesium carbonate suspended in water, has been introduced into use as a cathartic and antacid. *Dinneford's Magnesia* is a solution of this nature. According to Christison, it contains only nine grains of carbonate in the fluidounce, though alleged to contain twice that quantity. Its taste is more disagreeable than that of the undissolved carbonate. A formula for this preparation has been introduced into the British Pharmacopœia, with the name of *Liquor Magnesiae Carbonatis* (see page 724).

Adulterations and Tests.—The following are the official tests: "If a mixture of 1 Gm. of Magnesium Carbonate with 50 Cc. of water be heated to boiling, and, after cooling, filtered, the filtrate, if evaporated to dryness upon a water-bath, should leave not more than 0.001 Gm. of residue (limit of *foreign soluble salts*). Ten Cc. of a solution of the salt (1 in 50), prepared by the addition of sufficient acetic acid for solution, should not be rendered more than slightly opalescent within five minutes by ammonium oxalate T.S.

(limit of *calcium*). If 1 Gm. of Magnesium Carbonate be ignited in a porcelain crucible, the residue should weigh not less than 0.40 Gm. If 1 Gm. of Magnesium Carbonate be dissolved in 20 Cc. of diluted hydrochloric acid, the solution should be colorless and not give an immediate blue coloration upon the addition of potassium ferrocyanide T.S. (limit of *iron*), nor should another solution of the same strength respond to the Time-Limit Test for other *heavy metals* (see PART III, Test No. 121). If 0.400 Gm. of recently ignited and cooled Magnesium Carbonate be dissolved in 25 Cc. of normal sulphuric acid V.S., not more than 5.8 Cc. of normal potassium hydroxide V.S. should be required for neutralization, methyl-orange T.S. being used as indicator (each Cc. of normal sulphuric acid V.S. consumed, being equivalent to 5 percent. of pure magnesium oxide)." *U. S.* Magnesium carbonate may contain an alkaline carbonate or sulphate, or both, from insufficient washing; also sodium chloride, alumina, and calcium carbonate. If water boiled on it changes turmeric, an alkaline carbonate is indicated. If barium chloride produces a precipitate in the water, the presence of a sulphate or carbonate is shown, and if silver nitrate produces precipitation, a chloride is indicated. When dissolved in an excess of hydrochloric acid, an excess of ammonia will throw down alumina, which is almost always present in minute quantity, and ammonium oxalate, afterwards added to the filtered chloride solution, will throw down calcium oxalate if lime be present. When the same solution, nearly neutralized, is rendered blue by potassium ferrocyanide, iron is indicated.

Composition.—According to Berzelius, magnesium carbonate of commerce (*magnesia alba*) is a combination of three molecules of magnesium carbonate with one of magnesium hydroxide. According to Phillips, whose analysis agrees with a subsequent one by Fownes, four molecules of the carbonate are combined with one of the hydroxide and four of water. (*P. J.*, iii. 480.) The formula given by the British Pharmacopœia is $3\text{MgCO}_3 + \text{Mg}(\text{OH})_2 + 4\text{H}_2\text{O}$; in other words, a combination of three molecules of magnesium carbonate, one of magnesium hydroxide, and four of water, while the *U. S. Pharmacopœia* of 1890 made it $4\text{MgCO}_3 + \text{Mg}(\text{OH})_2 + 5\text{H}_2\text{O}$, which is retained in the *U. S. P.* (8th Rev.). The composition of this salt varies with the mode of preparation.

Uses.—Magnesium carbonate is antacid, and, by combining with acid in the stomach, becomes generally cathartic. When it undergoes no change in the alimentary canal it produces no purgative effect. Under these circumstances it may usually be made to operate by following it with draughts of lemonade. It is useful in all cases which require a laxative antacid, and, though prone to produce flatulence in consequence of the liberation of its carbon dioxide in the stomach and bowels, and therefore in

ordinary cases inferior to calcined magnesia, it sometimes operates favorably, in consequence of this very property, in *sick stomach* attended with acidity. Magnesium carbonate is also an excellent antilithic when uric acid is present in excess. It is best administered in water or milk. In order that it may be uniformly diffused through water, it should be previously rubbed down with syrup or ginger syrup. Magnesium carbonate is a useful agent for diffusing camphor and the volatile oils through water, in preparing unofficial medicated waters, and is also used with a similar purpose as a diffusing agent in preparing syrups or elixirs.

Dose, thirty to one hundred and twenty grains (2 to 7.7 Gm.).

Off. Prep.—Liquor Magnesii Citratis, *U. S.*; Trochiscus Bismuthi Compositus, *Br.* It is used also in several official syrups.

"It should contain, after ignition, not less than 96 percent. of pure Magnesium Oxide. It should be kept in well-closed vessels." *U. S.* "Light Magnesium Oxide, MgO, is prepared by exposing Light Magnesium Carbonate to a dull red heat." *Br.*

Magnesia Levis, Br., Light Magnesia; *Magnesia Calcinata*; *Magnésie calcinée, Fr. Od.*; *Magnésie, Fr.*; *Magnesia Usta, P. G.*; *Gebrannte Magnesia, G.*; *Ossido di magnesio, It.*; *Oxido magnesico, Sp.*

In the British Pharmacopœia 1885 directions were given for preparing two forms of magnesia, one called *Magnesia Levis*,¹ or *Light Magnesia*, from the *Light Carbonate*, and the other *Magnesia Ponderosa*, from the *Heavy Carbonate*. It is the former which corresponds with our ordinary magnesia. Neither Pharmacopœia gives a detailed process.

By exposure to a red heat, the water and carbon dioxide of the magnesium carbonate are expelled, and the earth is obtained pure. According to Black, the carbonate loses seventieths of its weight by calcination. Brande says that the loss varies from 50 to 60 per cent., of which from 15 to 20 per cent. is water:

About the close of the process the earth exhibits a luminous or phosphorescent appearance, which is said to be a good criterion of its freedom from carbon dioxide. (Duncan.) A more certain indication, however, is the absence of effervescence when hydrochloric acid is added

to a little of the magnesia, previously mixed with water. It is an error to suppose that a very intense heat is requisite in the calcination. The temperature of ignition is sufficient for the expulsion of the water and carbon dioxide, and any increase serves only to render the magnesia harder, denser, less readily soluble in acids, and consequently less useful as a medicine. In order to insure a pure product, care should be taken that the carbonate employed be free from lime. It should be rubbed to powder before being introduced into the pot or crucible, and, as in consequence of its lightness it occupies a very large space, the plan has been proposed of moistening and compressing it in order to reduce its bulk; but the French pharmaceutical writers direct that the vessels employed should be sufficiently large to contain a considerable quantity of the carbonate, without the necessity of resorting to compression.¹ The official direction, to keep the magnesia, after it has been prepared, in well closed vessels, is founded on the fact that it absorbs carbon dioxide and water from the air, but, as the absorption of the gas goes on very slowly, and that of water does not injure the preparation, the caution is often neglected. (See *P. J.*, 1898, 389.) The great bulk of the oxide renders its introduction into small bottles inconvenient. A four ounce bottle holds only about an ounce of the purest and finest magnesia. But its specific gravity is greatly increased by trituration, and four times the quantity may be thus pressed into the same space. The density of *Henry's Magnesia*, which is at least four times that of the oxide prepared in the ordinary way, has been ascribed to this cause. It has also been attributed to the influence of intense heat employed in the calcination. The conjecture has even been advanced, that this magnesia, which has enjoyed so great a popularity in England and this country, is prepared by precipitating a solution of magnesium sulphate by potassium hydroxide, as the product afforded by this plan is comparatively dense. It is asserted that the magnesia prepared from the carbonate procured by precipitating magnesium sulphate with potassium carbonate is softer to the touch and bears a closer resemblance to Henry's than that prepared from the ordinary carbonate. The fact is explained by the presence in such magnesia

¹ In a paper by A. Vée (*J. P. C.*, Avril, 1860, p. 84) it is stated that the magnesia of commerce, in consequence of imperfect preparation, is often found dense, granular, harsh, and of difficult solubility in the acids. To remedy this inconvenience the only method heretofore known was to prepare it in small quantities, and to stir the magnesia during calcination with an iron spoon. The difficulty in preparing it properly on the large scale depends upon the unequal action of the heat on large masses, so that the outer part becomes heated in excess before the inner is sufficiently so. To remedy this inconvenience, Vée uses a furnace and crucible of a peculiar shape, so arranged that the magnesia may not be in layers thicker than seven centimeters (2.7 inches), may be exposed equally to heat, and not longer exposed than may be necessary for its decomposition. For an account of the apparatus, and of the proper method of management, see *A. J. P.*, 1862, p. 522.

¹ "Take of Light Carbonate of Magnesium four ounces. Put it into a Cornish or Hessian crucible closed loosely by a lid, and expose it to a low red heat until a small quantity, taken from the centre of the crucible, cooled, moistened with water, and dropped into warm diluted sulphuric acid, causes no effervescence." *Br.* 1885.

of a little potassium sulphate, from which it is difficult entirely to free it in consequence of the sparing solubility of this salt, and of a portion of silica, which originally existed in the potassium carbonate employed to decompose the magnesium sulphate, and of which sodium carbonate is destitute. According to Richard Phillips, Jr., if equivalent quantities of crystallized magnesium sulphate and crystallized sodium carbonate be boiled together in water, the mixture evaporated to dryness, the residual salts calcined, and the sodium sulphate dissolved out by water, the magnesia obtained will be dense. (See *A. J. P.*, xvi. 118.) By packing the carbonate closely in the crucible, or by moistening and then compressing it strongly in a cloth, before calcination, a heavy magnesia is obtained. The advantages of Henry's magnesia, independently of the convenience of its less bulk, are its greater softness and more ready miscibility with water. A preparation similar to Henry's is made by T. J. Husband of Philadelphia. In reference to the preparation of heavy magnesia, T. H. Barr, after trying various methods, obtained the best results either by precipitating a hot concentrated solution of magnesium sulphate with a like solution of sodium carbonate, or by decomposing magnesium chloride by heat. (*A. J. P.*, xxvi. 193.) P. E. Alessandri proposes the following method, which is both simple and rapid, for preparing "heavy" calcined magnesia. Take ordinary calcined magnesia, free from carbonate, moisten it, in a mortar, with pure absolute alcohol, and triturate it, at first gently, afterwards with some force, but not rapidly. During the agitation, the magnesia is to be moistened three or four times with fresh portions of the alcohol, and the operation is suspended when the bulk of the magnesia appears to remain stationary. Then remove the mass, dry it, rub it to powder, and pass it through a sieve. The product occupies only about one-fifteenth of the original bulk; but it is too expensive for practical uses. (*N. R.*, March, 1882.)

Magnesia is now manufactured extensively in the United States, the domestic product having almost entirely supplanted that which was formerly imported from Great Britain. The Keasbey & Mattison Company have erected extensive works at Ambler, Pa., although the greater part of their output is magnesium carbonate, which is used in the arts mainly as a non-conductor of heat. This company also makes light and heavy calcined magnesia for medicinal purposes, and dolomite is now exclusively used as the source of the magnesium compounds. (See *Magnesii Carbonas* for further information.)

Pereira found *light magnesia*, under the microscope, to exhibit the same forms observed in the light carbonate, namely, one portion was amorphous and of a flocculent or granular consistence, and another was composed of fragments of prismatic crystals, while the *heavy magnesia* was homogeneous, exhibiting no traces

of crystals, and consisting of minute granules more or less cohering into small soft balls or masses. (*P. J.*, viii. 235.)

Properties.—Magnesium oxide or magnesia is a very light, white, inodorous powder, of a feeble alkaline taste. Its sp. gr. is commonly stated at 2.3. It was deemed infusible until melted by means of the oxyhydrogen blowpipe of Hare. When sufficiently heated, it conducts electricity and shines with an intense light, which fact is utilized in the Nernst lamp. Water sprinkled upon it is absorbed to the extent of about 18 per cent., but with scarcely any increase of temperature. It is almost insoluble, requiring, according to Fyfe, 5142 parts of water at 60° F., and 36,000 parts of boiling water, for solution. Water thus impregnated has no effect on vegetable colors, but magnesia itself produces a brown stain by contact with moistened turmeric paper. Magnesia is a metallic oxide, consisting of one atom of magnesium and one of oxygen. It is officially described as "a white, very bulky, and very fine powder, without odor, and having an earthy, but not a saline, taste. On exposure to the air, it slowly absorbs moisture and carbon dioxide. Almost insoluble in water, and insoluble in alcohol, but soluble in dilute acids. When moistened with water, it has a faintly alkaline reaction upon red litmus paper. On stirring 1 part of Magnesium Oxide with 15 parts of water, in a beaker, and allowing the mixture to stand for about half an hour, it will form a gelatinous mass of sufficient consistence to prevent it from dropping out when the beaker is inverted. A solution of Magnesium Oxide in diluted sulphuric acid, mixed with ammonium chloride T.S. and an excess of ammonia water, yields, with sodium phosphate T.S., a white, crystalline precipitate. If a mixture of 1 Gm. of Magnesium Oxide with 50 Cc. of water be heated to boiling, and, after cooling, filtered, the filtrate should not show more than a faintly alkaline reaction with red litmus paper, and when evaporated to dryness should not leave more than 0.005 Gm. of residue (limit of *foreign soluble salts*). If a mixture of 0.1 Gm. of Magnesium Oxide with 5 Cc. of water be heated to boiling, and, after cooling, be poured into 5 Cc. of acetic acid, solution should take place without the evolution of more than a few isolated gas bubbles (limit of *carbonate*). Ten Cc. of a solution of Magnesium Oxide (1 in 50), prepared by the addition of sufficient acetic acid for solution, should not be rendered more than slightly opalescent within five minutes by ammonium oxalate T.S. (limit of *calcium*). If 1 Gm. of Magnesium Oxide be dissolved in 50 Cc. of diluted hydrochloric acid, the solution should be colorless and not give an immediate blue coloration upon the addition of potassium ferrocyanide T.S. (limit of *iron*), and a solution of Magnesium Oxide (1 in 20) in diluted hydrochloric acid should not respond to the Time-Limit Test for other *heavy metals* (see PART III, Test No. 121). If Mag-

magnesium Oxide be exposed to a low red heat in a porcelain crucible, it should not lose more than 15 percent. of its weight (limit of *water of hydration*). If 0.400 Gm. of recently ignited and cooled Magnesium Oxide be dissolved in 25 Cc. of normal sulphuric acid V.S., not more than 5.8 Cc. of normal potassium hydroxide V.S. should be required for neutralization, methyl-orange T.S. being used as indicator (each Cc. of the normal sulphuric acid V.S. consumed being equivalent to 5 percent. of pure Magnesium Oxide)." U. S. "A bulky white powder differing from Heavy Magnesia only in its greater lightness, the volumes corresponding to the same weight being to each other in the ratio of three and a half to one." Br.

Magnesia is a white, very brilliant metal, of sp. gr. 1.75, resembling silver, malleable, fusible at a low temperature, and convertible into magnesia by the combined action of air and moisture. It burns with great facility, and yields by its combustion a light which is intensely white and very rich in actinic or chemically active rays, so that it finds wide application in signal lights and for photography. Many of the so-called "flash powders" contain metallic magnesium in a finely divided state as their basis. There is a magnesium hydroxide, possessing the formula $Mg(OH)_2$. With nitric and hydrochloric acids magnesia forms salts which are soluble in alcohol and very deliquescent. It is precipitated from its saline solutions by the pure alkalies in the state of a hydroxide, and by potassium and sodium carbonates as a carbonate, but it is not precipitated by the alkaline bicarbonates, nor by common ammonium carbonate.

Magnesia is liable to contain, as impurities, magnesium carbonate, lime, alumina, silica, and small quantities of the soluble salts employed or produced in the preparation of the carbonate from which it is procured. Lime, which is a very frequent impurity, and imparts to the magnesia a more strongly alkaline and more disagreeable taste, is detected by ammonium oxalate or potassium bicarbonate. Neither of these salts disturbs a neutral solution of pure magnesia in a diluted acid, but if lime is present, both produce a precipitate, the former of calcium oxalate, the latter of calcium carbonate. According to Wittstein, calcium oxalate is soluble in the neutral salts of magnesia, requiring 50 parts of magnesium chloride, and 90 of magnesium sulphate, and consequently there might be no precipitate, or one redissolved by the liquid, should the proportion of lime be very small. (*J. P. C.*, 4e sér., iii. 216.) As magnesia is completely dissolved by hydrochloric acid, silica and other impurities insoluble in that acid would be left behind. Alumina is indicated by the production of a precipitate when ammonia is added in excess to a solution of fifty grains of magnesia in a fluidounce of hydrochloric acid. If the magnesia contain a soluble sulphate or carbonate, barium chloride will reveal it by producing a precipitate with

water digested on the magnesia. Rochelle salt occurs as an impurity in magnesia, probably as the result of accident. (*A. J. P.*, Jan. 1873.)

Uses.—Magnesium oxide is antacid and laxative, and is much used, under the name of *calcined magnesia*, in *dyspepsia*, *sick headache*, *gout*, and other complaints attended with sour stomach and constipation. It is also a favorite remedy in the complaints of children, in which acidity of the *primæ viæ* is often a prominent symptom. Its antacid properties render it useful in *gravel* attended with an excessive production of uric acid. Its advantages over magnesium carbonate are that it may be given in a smaller dose and does not occasion flatulence.¹ The dose as a laxative is from thirty grains to a drachm (2.0 to 3.9 Gm.); as an antacid merely, or an antilithic, from ten to thirty grains (0.65 to 2.0 Gm.) twice a day. When it meets with no acid, it is apt to linger in the stomach or bowels, and may in that case be followed by lemonade. It should be administered in water or milk, and thoroughly triturated so as to render the mixture uniform. If mixed with less than 14 or 15 times its weight of water, and allowed to stand for a day or two, magnesia is apt to form a more or less concrete mass, owing to the production of a hydroxide. This change does not take place, or at least takes place much less readily, when magnesia already saturated with moisture is employed instead of that freshly calcined. In this connection Duncan recommends boiling the magnesia for a few moments with half the quantity of water prescribed to prevent subsequent caking. It has been conjectured that anhydrous magnesia might prove injurious to the stomach by solidifying its liquid contents, and the oxide which has become saturated with moisture by exposure to a damp air is preferably recommended. Freshly precipitated magnesium hydroxide will serve as an antidote to arsenic trioxide, though less efficient than ferric hydroxide. The experiments of Carles have shown that the soluble *magnesium saccharate* is not superior as an antidote for arsenic to simple magnesia. Ohleyer (*L. L.*, July, 1873) employs magnesia as a dressing in *ulcers* and *abrasions*, while Vergely recommends for *burns* calcined magnesia triturated with milk so as to form a paste, which should be applied thickly several times a day.

Dose, thirty to sixty grains (2.0 to 3.9 Gm.).

Off. Prep.—*Ferri Hydroxidum cum Magnesii Oxido*, U. S.; *Fluidextractum Rhamni Purshianæ Aromaticum*, U. S.; *Pulvis Rhei Compositus*, U. S., Br.

¹ *Trochisci Magnesie*. U. S. 1880. *Troches of Magnesia*.—"Magnesia, three hundred grains (19.50 Gm.); Nutmeg, in fine powder, fifteen grains (1.00 Gm.); Sugar, in fine powder, nine hundred grains (58.50 Gm.); Mucilage of Tragacanth, a sufficient quantity, to make one hundred troches. Rub the Magnesia and powder together until they are thoroughly mixed; then, with Mucilage of Tragacanth, form a mass, to be divided into one hundred troches." U. S. These each contain three grains (0.20 Gm.) of Magnesia, and are useful in acidity of the stomach, especially when attended with constipation.

MAGNESII OXIDUM PONDEROSUM.

U. S. (Br.)

HEAVY MAGNESIUM OXIDE, HEAVY MAGNESIA
(Magnesia Ponderosa, Pharm. 1890)

(măg-ně'si-i őr'ł-düm pön'de-rő'süm)

MgO = 40.06

"A white, dense, and very fine powder, which should conform to the reactions and tests given under *Magnesii Oxidum*. It differs, however, from the latter in not readily uniting with water to form a gelatinous hydroxide." *U. S.* "Heavy Magnesium Oxide, MgO, is prepared by exposing Heavy Magnesium Carbonate to a dull red heat." *Br.*

Magnesia Ponderosa, Br., Heavy Calcined Magnesia; Oxide of Magnesium; Magnésie Calcinée pesante, *Fr.*; Schwere gebrannte Magnesia, *G.*

This was directed, in the British Pharmacopœia 1885, to be prepared precisely in the same manner as light magnesia, using, however, the heavy carbonate (Heavy Magnesium Carbonate, *Br.*). It is described by the *Br. Ph.* 1898 as "a white powder, insoluble in water, but readily dissolved by acids, the solutions affording the reactions characteristic of magnesium. It should yield no characteristic reaction with the tests for iron, aluminium, calcium, or carbonates, and only the slightest reactions with the tests for chlorides or sulphates. When heated to dull redness it should lose little or no weight." *Br.* The two varieties of light and heavy magnesia differ only in their weight in the same bulk, the volumes corresponding to the same weight being to each other in the ratio of three and one-half to one. (See *Magnesii Oxidum*, page 753.)

Dose, thirty to sixty grains (2 to 3.9 Gm.).

MAGNESII SULPHAS. U. S., Br.

MAGNESIUM SULPHATE [Epsom Salt]

(măg-ně'si-i sũl'phās)

 $\text{MgSO}_4 + 7\text{H}_2\text{O} = 244.69$

"It should contain not less than 99.7 percent. of pure Magnesium Sulphate [$\text{SO}_2.\text{O}_2\text{Mg} + 7\text{H}_2\text{O}$], and should be kept in well-closed vessels." *U. S.* "Magnesium Sulphate, $\text{MgSO}_4, 7\text{H}_2\text{O}$, may be prepared by the interaction of the native magnesium carbonates and diluted sulphuric acid; or by purifying the native sulphate." *Br.*

Cod.*; Sel d'Epsom, Sel de Sedlitz, Sel amer, *Fr.*; Magnesium sulfuricum, *P. G.*; Magnesiumsulfat, Schwefelsaures Magnesia, Bittersalz, *G.*; Solfato di magnesio, Sulfato magnesico, *Sp.*

Magnesium Sulphate is a constituent of sea water, and of some saline springs. It also occurs native, either crystallized in slender, pris-

matic, adhering crystals, or as an efflorescence on certain rocks and soils which contain magnesia and a sulphate or sulphide. In the United States it is found in the great caves so numerous to the west of the Alleghany Mountains. In one of these caves, near Corydon in Indiana, it formed a stratum on the bottom several inches deep, or appeared in masses sometimes weighing ten pounds, or disseminated in the earth of the cavern, one bushel of which yielded from four to twenty-five pounds of the sulphate. It also appeared on the walls of the cavern, and, if it was removed, acicular crystals again appeared in a few weeks. (Cleveland.)

Under the name of *kieserite*, a mineral is obtained from the saline deposits at Stassfurt, in Germany, which consists chiefly of impure magnesium sulphate. The production of kieserite for the year 1901 was 27,088 tons, and for 1902, 27,576 tons. It is used as a source for preparing magnesium sulphate, and is exported from Germany; for a historical paper on Epsom salt by M. I. Wilbert see *Proc. A. Ph. A.*, 1904, 351.

Magnesium sulphate was originally procured by evaporating the waters of saline springs at Epsom, in England. Grew prepared it in this manner in 1675. It was afterwards discovered that the brine remaining after the crystallization of common salt from sea water furnished by careful evaporation precisely the same salt, and, as this was a much cheaper product, it superseded the former. The residual brine, or bittern, consists of magnesium sulphate and magnesium and calcium chlorides. As the magnesium sulphate crystallizes first, it may with proper care be obtained nearly pure, although most frequently the salt prepared in this way is deliquescent from the presence of magnesium chloride. It may be freed from this impurity by washing the crystals with their own saturated solution. It was from this source that the greater part of the Epsom salt of commerce was long obtained in Europe. The salt works of New England supplied our own market with an impure and deliquescent sulphate. With the improvements of chemistry, other and better processes have been adopted. In the neighborhood of Genoa and Nice, magnesium sulphate is prepared in large quantities from a schistose rock containing magnesia and iron sulphide. The mineral is roasted, and exposed in heaps for some months to the action of air and water. It is then lixiviated, the ferrous sulphate decomposed by lime water, and the salt obtained pure by repeated solution and crystallization.

William Henry of Manchester, whose calcined magnesia became famous throughout the world, took out a patent for a mode of preparing magnesia and its salts from the double magnesium and calcium carbonate,—the *dolomite* of mineralogists. His process was to drive off the carbon dioxide by heat, and to convert the remaining earth into hydroxides. He treated these with a sufficient quantity of hydrochloric

acid to dissolve out the lime, and then converted the magnesia into a sulphate either by sulphuric acid or by ferrous sulphate.

The salt is extensively manufactured in Baltimore and Philadelphia from a silicious magnesium hydroxide. This mineral occurs in veins in the serpentine and other magnesian rocks which abound in the neighborhood of Baltimore and in the southern counties of Pennsylvania. The advantage which it possesses over the dolomite, in the preparation of this salt, is the almost entire absence of lime, owing to which there is little or no waste of acid, and the operation is much simplified. The mineral is reduced to a fine powder and saturated with sulphuric acid. The mass is then dried and calcined at a red heat, in order to convert any ferrous sulphate which may be present into ferric oxide. It is then dissolved in water, and calcium sulphide added to separate any remaining portion of iron. The salt is crystallized and dissolved a third time, in order to purify it. The sulphate prepared by this process is generally very pure and clean, although it sometimes contains a trace of ferrous sulphate. A very pure magnesium sulphate free from chloride is obtained as a side product in the manufacture of carbon dioxide from magnesite when sulphuric acid is used to decompose the carbonate. This industry has assumed large proportions because of the demand for liquified carbon dioxide in the manufacture of aerated and effervescing mineral waters.

Properties.—Magnesium sulphate is in "small, colorless, prismatic needles or rhombic prisms, without odor, and having a cooling, saline, and bitter taste; slowly efflorescent in the air. Soluble in 0.85 part of water at 25° C. (77° F.), and in 0.13 part of boiling water; insoluble in alcohol. When heated to 52° C. (125.6° F.), or exposed to warm air, the salt loses one molecule of water, and is converted into a white powder. At about 130° C. (266° F.) it still retains 1 molecule of water, and at a temperature between 200° and 238° C. (392° and 460.4° F.) it is rendered anhydrous. An aqueous solution of Magnesium Sulphate is neutral to litmus paper. When mixed with ammonium chloride T.S. and ammonia water, the aqueous solution of the salt yields with sodium phosphate T.S., a white crystalline precipitate. With barium chloride T.S. it yields a white precipitate insoluble in hydrochloric acid. Ten Cc. of the aqueous solution of the salt (1 in 20) should not respond to the Time-Limit Test for *heavy metals* (see PART III, Test No. 121). Five Cc. of the aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzeit's Test for *arsenic* (see PART III, Test No. 17)." *U. S.* "Soluble in 1 part of cold water, and possessing a bitter taste. It affords the reactions characteristic of magnesium and of sulphates. 0.5 gramme dissolved in 250 cubic centimetres of water, when set aside for twelve hours with a mixture of solution of ammonia, solution of ammonium

chloride, and solution of sodium phosphate, yields a precipitate which, when thoroughly washed, dried, and heated to redness, weighs 0.22 gramme. Magnesium Sulphate should yield no characteristic reaction with the tests for iron, aluminium, zinc, calcium, sodium, potassium, ammonium, or nitrates, and only the slightest reactions with the tests for chlorides." *Br.* It usually occurs in small acicular crystals, which are produced by agitating the solution while crystallizing. It slowly effloresces in the air.

Magnesium sulphate is completely decomposed by potassium and sodium hydroxides and their carbonates, by lime, barium and strontium oxides, and their soluble salts. Ammonia partially decomposes it, and forms with the remainder a double sulphate. Potassium and sodium bicarbonates do not decompose it, except by the aid of heat. An economic use which has been recommended of magnesium sulphate is the addition of a strong solution to ordinary white-wash, whereby a beautiful whiteness may be given to walls and ceilings. A little of it, moreover, added to starch considerably increases its stiffening properties, and at the same time in some degree resists the action of fire. (*Chem. News*, April, 1867.)

Uses.—Magnesium sulphate is an active but safe cathartic, operating with little pain or nausea, and producing watery stools. It is more acceptable to the stomach than most medicines of its class, and will often be retained when others are rejected. Like many of the other neutral salts, it is refrigerant, and may be made to act as a diuretic by keeping the skin cool and walking about after it has been taken. It is well adapted to the treatment of *fevers and inflammatory affections*. It is also useful in *colic and obstinate constipation*, and may be employed in most cases which require the use of a cathartic without being attended with debility or relaxation of the stomach and bowels. The medium dose is an ounce (31 Gm.), but advantage often results from its administration in divided doses frequently repeated. It is often given in combination with other medicines, especially with senna, the gripping effect of which it tends to obviate. The most agreeable form for administering the salt, and that in which it usually agrees best with the stomach, is a solution in carbonic acid water with lemon syrup. By Henry of Dublin, it is highly recommended in connection with diluted sulphuric acid. To seven ounces of a saturated aqueous solution of the salt he adds an ounce of the diluted sulphuric acid, and gives a tablespoonful of the mixture for a dose, in a wineglassful of water.

The experiments of Recke, Hay, and Henry Curci show that when injected into the veins magnesium sulphate acts as a violent poison, producing at first increase of the blood pressure with slowing of the pulse, and finally lowering of the blood pressure, quickening of the pulse, and death, sometimes by failure of

respiration, at other times by cardiac arrest. As Christison reported the case of a boy ten years old who was said to have been killed by two ounces of the salt without the induction of purgation, it is possible that under some circumstances very large amounts of magnesium sulphate given by the mouth may be sufficiently absorbed to produce poisonous effects.

Many years ago the hypodermic use of magnesium sulphate as a purgative was reported upon favorably by clinicians, but certainly this use of the remedy failed to become at all general. The method has been recommended by Fineke, Rohé, Wade, James Wood, and by MacCallum, who assert that the hypodermic injection of from one and a half to four and a half grains of the magnesium sulphate will produce watery stools in the majority of cases, but no purgation follows in from twenty to forty per cent. of the cases. The effects of the injection of large doses into the lower animals must cause some hesitation in the use of large amounts of the magnesium sulphate hypodermically. Rectal injections of from one to three ounces of the saturated solution of the magnesium sulphate often act very favorably, but are somewhat uncertain.

Dose, one to eight drachms (3.9 to 31 Gm.).

MAGNESII SULPHAS EFFERVESCENS. U. S., Br.

EFFERVESCENT MAGNESIUM SULPHATE (măg-nē'sŭ-i sŭl'phās ēf-fer-vēs'cens)

Magnesium Sulphuricum Effervescens; Magnesii Sulphas Effervescens; Effervescent Sulphate of Magnesia; Effervescent Epsom Salt; Brausendes Magnesiumsulfat, *G.*; Sulfato magnesico effervescente, *Sp.*

* "Magnesium Sulphate, uneffloresced crystals, five hundred grammes [or 17 ounces av., 279 grains]; Sodium Bicarbonate, dried and powdered, four hundred and three grammes [or 14 ounces av., 94 grains]; Tartaric Acid, dried and powdered, two hundred and eleven grammes [or 7 ounces av., 193 grains]; Citric Acid, uneffloresced crystals, one hundred and thirty-six grammes [or 4 ounces av., 349 grains], to make one thousand grammes [or 35 ounces av., 120 grains]. Dry the Magnesium Sulphate on a water-bath, until it ceases to lose weight, then, after powdering the dry salt, mix it intimately with the Citric Acid, which has previously been powdered, and the Tartaric Acid, and thoroughly incorporate the Sodium Bicarbonate. Place the mixed powders on a plate of glass or in a suitable dish, in an oven heated to between 93° and 104° C. (199.4° and 219.2° F.). When the mixture has acquired a moist consistence by the aid of careful manipulation with a wooden

spatula, rub it through a No. 6 tinned-iron sieve, and dry the granules at a temperature not exceeding 54° C. (129.2° F.). Keep the product in well-stoppered bottles." *U. S.*
"Magnesium Sulphate, in crystals, 50 ounces (Imperial) or 500 grammes; Sodium Bicarbonate, in powder, 36 ounces (Imp.) or 360 grammes; Tartaric Acid, in powder, 19 ounces (Imp.) or 190 grammes; Citric Acid, in powder, 12½ ounces (Imp.) or 125 grammes; Refined Sugar, in powder, 10½ ounces (Imp.) or 105 grammes. Dry the Magnesium Sulphate at about 130° F. (54.4° C.) until it has lost twenty-three per cent. of its weight; powder the product; mix it with the Refined Sugar and then with the other ingredients. Place the mixture in a dish or pan of suitable form heated to between 200° and 220° F. (93.3° and 104.4° C.). When the mixture, by the aid of careful manipulation, has assumed a granular character, separate it into granules of uniform and convenient size by means of suitable sieves. Dry the granules at a temperature not exceeding 130° F. (54.4° C.). The product should weigh about 100 ounces (Imp.) or 1000 grammes." *Br.*

This effervescent salt is intended to furnish a less disagreeable form of administering Epsom salt.

Dose, from two drachms to one ounce (7.7 to 31 Gm.).

MALTUM. U. S.

MALT

(māl'tŭm)

"The grain of barley, *Hordeum distichon* Linné (Fam. *Gramineæ*), partially germinated artificially, and then dried." *U. S.*

Maltum Hordel; Barley Malt; Malt d'Orge, *Fr.*; Gerstenmalz, *Malz, G.*

Preparation.—Malt is prepared on an enormous scale for brewing purposes in all parts of the world where the climate is suited to the growth of barley. The object of the process for making malt, commonly known as malting, is to allow germination of grain to go just far enough to develop the maximum amount of diastase, the ferment by which the starch is converted into sugar, which may afterwards undergo the alcoholic fermentation during the process of brewing. In order to achieve this, the barley is first steeped,—i.e., allowed to remain one or two days in cold water, of which it absorbs from 10 to 50 per cent.; second, *couché*,—i.e., thrown into heaps upon a floor and allowed to develop heat and germinate; third, when the *acrosipire* or shoot is one-third the length of the grain, the latter is *floored*,—i.e., spread upon wide floors to dry; fourth, *kiln-dried*,—i.e., exposed to such a temperature as thoroughly to dry it and kill the young plant. If the temperature be raised high enough to scorch the grain, it becomes *Amber Malt*, or *Black Malt*, according to the extent of the cara-

melizing. Besides the diastase, a second soluble ferment is formed during the malting process, the so-called *peptase*, which in the after-mash process changes the proteids of the malt into peptones and parapeptones which give nutritive value to the beer.

Properties.—It is composed of germinated grains with the radicles and acrospires adhering, and is officially described as follows: "Yellowish or amber-colored grains, shading to brown; crisp when fractured, the interior surface whitish, or tinged with brown if the grains have been heated sufficiently to cause caramelization. It should have an agreeable, characteristic odor, and a sweet taste due to the conversion of the starch in the seed into maltose, through the action of diastase. Malt should float on cold water. The solid soluble constituents of Malt, obtained by evaporating an aqueous infusion to dryness, should weigh not less than 70 percent. of the dried Malt from which they are derived. The acidity of Malt (calculated as lactic acid), should not exceed 0.3 percent." *U. S.*

Uses.—Malt is not itself used directly in medicine, but is official as the basis of Malt Extract. From it are also prepared the so-called *Malt Liquors* by making an infusion (*wort*) of the bruised malt, adding hops and various other substances, and fermenting. *Ale*, *brown stout*, and *porter* are made by rapid fermentation at a comparatively high temperature (75° F.), while *lager beer* is prepared by a very slow, prolonged fermentation at a low temperature.

MANGANI DIOXIDUM PRÆCIPITATUM. U. S. (Br.)

PRECIPITATED MANGANESE DIOXIDE
[To replace Mangani Dioxidum, Pharm. 1890]

(măn'gā-nī dī-ōx'ī-dūm præ-cīp'ī-tā'tūm)

"Chiefly Manganese Dioxide [$\text{MnO}_2 = 86.36$] with small amounts of other oxides of manganese, corresponding to not less than 80 percent. of Manganese Dioxide." *U. S.* "The powdered native peroxide, MnO_2 , pyrolusite." *Br. Appendix.*

Manganese Peroxide, Br. 1898, Appendix: Manganium Hyperoxydatum; Oxydum Manganicum; Peroxide of Manganese; Deutoxide of Manganese, Black Oxide of Manganese, Pyrolusite; Oxyde (Bl.) de Manganèse, *Fr. Cod.*; Oxyde noir de Manganèse, *Fr.*; Braunstein, *G.*; Bissido di manganese, *It.*; Manganesa, Pyrolusita, *Sp.*

• "Manganese Sulphate, fifty grammes [or 1 ounce av., 334 grains]; Ammonia Water, two hundred and fifty cubic centimeters [or 8 fluidounces, 218 minims]; Solution of Hydrogen Dioxide, two hundred and fifty cubic centimeters [or 8 fluidounces, 218 minims]; Distilled Water, a sufficient quantity. Dissolve the Manganese Sulphate in one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Distilled Water. Dilute the Ammonia Water with an equal volume of Distilled Water, and

mix it with the Solution of Hydrogen Dioxide, which has also been diluted with an equal volume of Distilled Water. Pour the mixed solutions, slowly, with constant stirring, into the solution of Manganese Sulphate. Allow the mixture to stand for one hour, stirring frequently. Then decant the supernatant clear liquid from the precipitate, and wash the latter repeatedly by affusion and decantation with hot Distilled Water, using one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] each time. Collect the precipitate on a plain filter, and continue the washing with hot Distilled Water until the washings no longer have an alkaline reaction upon red litmus paper, and produce no turbidity when mixed with barium chloride test solution. Allow the precipitate to drain, then dry it at 150° C. (302° F.)." *U. S.* The official precipitated manganese dioxide of the U. S. P. (8th Rev.) is prepared from manganous sulphate by the simultaneous action of ammonium hydroxide (which precipitates manganese hydroxide), and of hydrogen dioxide, which oxidizes this at once into the hydrated manganese dioxide. This precipitate, after thorough washing, is dried at 150° C., so that there remains MnO_2 as the final product.

A change was made in the U. S. P. (8th Rev.) and a process for preparing manganese dioxide was introduced; this was due to the fact that it has become very difficult to obtain native manganese dioxide of good quality; the official precipitated manganese dioxide is of course more expensive than the native oxide, but much to be preferred in making pharmaceutical preparations. *Metallic manganese* was discovered by Scheele and Gahn in 1774, and is obtained from the native black oxide by intense ignition with charcoal. As obtained by C. Brunner, manganese is brittle, grayish white, and very hard, being capable of cutting glass and scratching the best tempered steel. It is susceptible of the most perfect polish, and decomposes water at a boiling temperature. Its sp. gr. is about 7.2.

Déville obtained the metal by heating the black oxide with charcoal in excess in a lime crucible. The metal thus obtained is more refractory than iron, while that procured by Brunner fused at the same heat as white cast iron. Greene and Wahl have lately succeeded in getting the metal in large masses by the reduction of the ores with the aid of silicon, which they add in the form of an iron silicide. The atomic weight of manganese is 54.6. With oxygen it forms five and possibly seven compounds: MnO , Mn_2O_3 , Mn_3O_4 , MnO_2 , and Mn_2O_7 . The monoxide is of a light green color, and is the oxide present in or corresponding to manganous salts. The sesquioxide is black or dark brown, when in the hydrated state; the magnetic oxide, Mn_3O_4 , is red; the dioxide is black; and the permanganic oxide, Mn_2O_7 , is, when in the free state, a very unstable dark reddish-brown liquid. The monoxide is

a stable base, the sesquioxide is feebly basic, and the dioxide when acted upon by acids yields manganous salts, while oxygen is evolved. The highest oxide is acid-forming, yielding permanganic acid, HMnO_4 , the salts of which are known as permanganates. (See *Potassii Permanganas*.) There exists also an acid, H_2MnO_4 (manganic), of which the salts formed are called manganates. The oxide corresponding is not known, however. Metallic manganese is an occasional constituent of organic matter. It has been detected in minute quantity in bone, hair, brain, epidermis, gastric juice, bile, urine, and pus, and has been found by Millon and others in the blood. Glénard of Lyons, denies that it is a normal constituent of the blood, although sometimes present, but the evidence of numerous experimenters shows that it generally exists in that fluid, and when not detected it may be because the quantity present is too minute to be easily discovered.¹ According to E. Davy, potassium hydroxide, dissolved in an equal weight of water, forms a delicate test for manganese, not obscured by the presence of other metals. The smallest portion of matter suspected to contain the metal, being finely pulverized or in solution, is placed upon a slip of silver foil, and a drop of the test added. Upon evaporation to dryness with a spirit lamp, and raising the heat, the characteristic green potassium manganate will appear on the foil. (*Chem. Gaz.*, March 15, 1854.) Manganese is a constituent of all arable land, and is found in the ashes of most of the vegetables which form the food of man and the inferior animals. In the mineral kingdom it occurs sometimes as silicate (*rhodonite*) or carbonate (*diallogite*), and very abundantly as the black oxide, or dioxide, called *pyrolusite*. It is the latter mineral which constitutes the British official oxide.

But few mines of manganese dioxide exist, though the metal itself is very generally diffused throughout the mineral kingdom. It occurs most abundantly in the Russian Caucasus, which furnishes nearly half of the annual production of the world, in Chili, Cuba, Great Britain, Turkey, and Australia. In the United States it occurs in largest amount at Crimora, Va., Cartersville, Ga., and Batesville, Ark.; other isolated localities exist in California, Utah, Alabama, and Tennessee. The amount of manganese ore mined in the United States is at present very small, being only 3,146 tons in 1904, although large quantities of manganiferous iron ores, manganiferous silver ores and manganiferous zinc residues are obtained, which go into the manufacture of spiegeleisen and ferro-manganese. On the other hand, very pure manganese ore is imported chiefly from the Caucasus, the amount in 1905 having been 257,033 tons. It comes packed in casks or barrels, generally in lumps and coarse powder, just as it is

dug out of mines, though occasionally it is received from England in a pulverized condition. It is a good rule to buy it unpowdered, as its quality can be better judged in that state. A dark shining crystalline appearance is an indication of good quality, although an assay will alone determine its quality with certainty.

Properties.—Manganese dioxide, as it occurs in nature, is very diversified in its appearance. Its sp. gr. varies from 4.7 to 4.9. It is found sometimes in brilliant needle-shaped crystals, often in compact masses having the metallic lustre, but far more frequently in the form of a dull earthy-looking substance of a black or brown color. It is purest when crystallized. As it occurs in commerce, it is usually in the form of a black powder, insoluble in water, and containing more or less oxidized iron, calcium carbonate, barium sulphate, and earthy matter. Iron, which is rarely absent, is detected by the production of a greenish or blue tint on the addition of potassium ferrocyanide to its hydrochloric solution. When exposed to a red heat it yields a portion of its oxygen, and is reduced to manganoso-manganic oxide. Hence its use in obtaining that gas. Good samples, after being dried, lose, when heated to whiteness, 12 per cent. of oxygen. It is distinguished from antimony sulphide by its infusibility, and by causing the evolution of chlorine on being heated with hydrochloric acid. When of a brown color, it is not of good quality.

The U. S. Pharmacopœia describes the precipitated manganese dioxide as "a heavy, very fine, black powder, without odor or taste; permanent in the air. Insoluble in water or alcohol. It is not affected by concentrated sulphuric acid, but when heated with this acid it is converted into manganous sulphate, with the evolution of oxygen. When heated with hydrochloric acid, it is converted into manganous chloride, with the evolution of chlorine. At a red heat Precipitated Manganese Dioxide gives off oxygen, and is converted into reddish-brown manganoso-manganic oxide (Mn_2O_3). On intimately mixing 1 part of the Dioxide with 1 part of potassium hydroxide and 1 part of potassium chlorate, introducing the mass into a crucible, moistening with water, drying and igniting, a dark fused mass is obtained which yields, with water, a green solution, changing to purplish-red on being boiled, or on the addition of diluted sulphuric acid. If to 1 Gm. of the Dioxide and 2 Gm. of oxalic acid, 20 Cc. of water be added, followed by 3 Cc. of sulphuric acid, and the mixture digested for several hours on a water-bath, complete solution should be effected (absence of antimony sulphide and insoluble substances). If 0.2 Gm. of Precipitated Manganese Dioxide be dissolved in a mixture of 50 Cc. of tenth-normal oxalic acid V.S. and 3 Cc. of sulphuric acid contained in a flask and heated on a water-bath, the resulting solution, after dilution with 100 Cc. of warm water, should

¹ For an elaborate article on the absorption of manganese, see A. E. P. P., xviii. p. 129.

require the addition of not more than 13 (12.95) Cc. of tenth-normal potassium permanganate V.S. to produce a slight pink tint (corresponding to not less than 80 percent. of pure Manganese Dioxide)." *U. S.*

Uses.—Manganese dioxide is deemed tonic and alterative. When slowly introduced into the system, as happens to those engaged in grinding the mineral, it acts, according to Coupar of Glasgow, as a cumulative poison, inducing a disease which begins with a staggering gait and ends in paraplegia. It has been used in *amenorrhœa*, *syphilis*, *chlorosis*, *scurvy*, and various *skin diseases*, especially *itch* and *porrigo*. It has been employed, in a purified state, with alleged great advantage by Arthur Leared, in *stomachic pains* of a purely nervous character, such as are apt to come on after eating. He has also found it useful in *pyrosis*, and in other irritable states of the stomach which are purely functional. It has the advantage over the preparations of bismuth, in these cases, that it does not constipate. (*Glasgow Med. Journ.*, Jan. 1865, p. 79.) For external use, an ointment may be made of one or two drachms of the oxide to an ounce of lard. The hypophosphite and the sulphate are official. For other compounds of manganese, see PART II.

The native oxide is used in the arts for obtaining chlorine in the manufacture of bleaching powder, for giving a black glazing to pottery, and for freeing glass from the color which it derives from iron. In the laboratory it is employed to obtain oxygen and chlorine, and to form the salts of manganese. It is also used for liberating chlorine from hydrochloric acid and from sodium chloride, and iodine from sodium iodide contained in kelp.

Dose, three to twenty grains (0.2 to 1.3 Gm.).

MANGANI HYPOPHOSPHIS. U. S.

MANGANESE HYPOPHOSPHITE

(măn'gā-nī hŷ-pō-phōs'phīs)

"It should contain not less than 97 percent. of pure Manganese Hypophosphite [$(\text{PH}_2\text{O.O})_2\text{Mn} + \text{H}_2\text{O}$], and be kept in well-stoppered vials." *U. S.*

Manganum Hypophosphorolum; Manganous Hypophosphite; Hypophosphite de Manganèse, Hypophosphite manganoux, *Fr.*; Unterphosphorigsaures Manganoxydul, *G.*

Preparation.—Manganese hypophosphite may be prepared by the interaction of manganese sulphate and calcium hypophosphite by mixing a solution containing 1.31 parts of the former with a solution containing 1 part of the latter, filtering out the precipitated calcium sulphate, evaporating and crystallizing. This salt was introduced into the *U. S. P.* (8th Rev.) solely for its use in making the Compound Syrup of Hypophosphites.

Properties.—Manganese hypophosphite is officially described as follows: "A pink crystalline powder, odorless, and nearly tasteless; permanent in the air. Soluble in 6.6 parts of water at 25° C. (77° F.), and in 6 parts of boiling water; almost insoluble in alcohol. The aqueous solution of the salt (1 in 20) is neutral to litmus paper, and yields, with ammonium sulphide T.S., a salmon-colored precipitate of manganese sulphide, soluble in acetic acid. When strongly heated in a dry test-tube, the salt evolves spontaneously inflammable hydrogen phosphide gas, and on complete ignition leaves a residue of manganous pyrophosphate. Manganese Hypophosphite is readily oxidized by nitric acid and other oxidizing agents. If a small quantity of an aqueous solution of the salt (1 in 20) be acidulated with hydrochloric acid, and mercuric chloride T.S. added in excess, a white precipitate of mercurous chloride will be produced, which, upon further addition of the acidulated solution, is reduced to metallic mercury. If to 0.5 Gm. of the salt 5 Cc. of acetic acid be added, no effervescence should occur (absence of *carbonate*). If 0.25 Gm. of the salt be boiled with 10 Cc. of potassium hydroxide T.S., a light salmon-colored precipitate will be produced which gradually acquires a brown color on exposure to the air, and if the filtered liquid, after being slightly acidulated with hydrochloric acid and then rendered alkaline with ammonia water, be divided into two portions, one should yield no precipitate upon the addition of magnesia mixture T.S. (absence of *phosphate*), while the remaining portion should not be affected by ammonium oxalate T.S. (absence of *calcium*). If 5 Cc. of the aqueous solution of the salt (1 in 10) be poured into an evaporating dish containing 3 Cc. of nitric acid, diluted with about 10 Cc. of water and evaporated to dryness on a water-bath, the residue should not respond to the Modified Gutzeit's Test for *arsenic* (see PART III, Test No. 17)." *U. S.*

Uses.—See *Calcii Hypophosphis*.

Dose, three to five grains (0.2 to 0.32 Gm.).

Off. Prep.—Syrupus Hypophosphitum Compositus, *U. S.*

MANGANI SULPHAS. U. S.

MANGANESE SULPHATE [Manganous Sulphate]

(măn'gā-nī sŭl'phās)

"It should contain not less than 99.5 percent. of pure Manganese Sulphate [$\text{SO}_2.\text{O}_2\text{Mn} + 4\text{H}_2\text{O}$], and should be kept in well-stoppered bottles." *U. S.*

Manganesi Sulphas. *U. S.* 1870; Manganum Sulphuricum, Sulfas Manganosus; Sulfate de Manganèse, *Fr. Cod.*; Sulfate manganoux, *Fr.*; Schwefelsaures Manganoxydul, Mangansulfat, *G.*; Sulfato manganoso, *Sp.*

This salt may be prepared by heating the native black oxide with concentrated sulphuric acid. Oxygen is thereby evolved, and the sulphate is formed. The product, when exhausted by water, furnishes a solution of the salt which must be heated nearly to the boiling point, and treated with manganese carbonate, added in small portions at a time, which will precipitate any iron present, and change the color of the liquid from a dark red to a pale rose tint. The liquid is then filtered, evaporated to the consistence of a thin syrup, and set aside to crystallize. C. Lewis Diehl has obtained by means of the following process an abundant product of the pure salt. A mixture of 5 parts of black manganese oxide and 0.75 part of coarsely powdered charcoal is exposed to a red heat, in a covered crucible, until all the charcoal is consumed. The contents of the crucible, after cooling, are put into a porcelain dish, and treated with 6.5 parts of sulphuric acid. The whole is then evaporated to dryness, and the residue, being returned to the crucible, is again heated to redness. When cool, the mass is rubbed to powder if necessary, and treated twice with eight parts of boiling water, and the liquors, having been mixed, are filtered, evaporated until a pellicle appears, and set aside to crystallize. It is important that the liquid should be removed from the sand bath as soon as the pellicle begins to form, as, if the heat be continued longer, an insoluble sulphate will be deposited. If the black manganese oxide employed be of good quality, a pure sulphate will be obtained, any salt of iron or copper present being rendered insoluble by the heat. (*A. J. P.*, 1867.) Laster's process is as follows:

"Take of Black Oxide of Manganese 40 parts, Commercial Hydrochloric Acid 200 parts. Dissolve the black oxide in the acid beneath a chimney-flue, and, when solution is complete, and chlorine no longer evolved, mix very gradually 53 parts of sulphuric acid with the reddish liquid; continue the evaporation beneath the flue until acid vapor is no longer driven off, and the mass becomes dry. Dissolve this mass in 350 parts of water heated to the boiling point. Treat the solution with manganese carbonate until it becomes rose-red, filter or decant, evaporate and crystallize." (*A. J. P.*, 1868.) F. Mahla of Chicago, proposes to utilize chlorine residues. He takes the liquid remaining in the retort after the preparation of chlorine, adds to it sodium carbonate sufficient to precipitate all the metallic oxides, or at least to cause a slight alkalinity, collects the precipitate thus produced on a muslin filter, and washes it with pure water, until the filtrate no longer produces an obvious reaction with silver nitrate. Three-fourths of the moist mass are removed from the filter to an evaporating dish, and sufficient diluted sulphuric acid is added to dissolve it completely. The solution is heated nearly to the boiling point, and the remaining fourth of the mass

from the filter is gradually added to it, until the liquid, after being filtered, is no longer blackened by tannic acid. The whole solution is then filtered, and the filtrate, with the waters, after washing, is evaporated to crystallization. The first crop of crystals is sometimes contaminated with calcium sulphate, from the calcium carbonate in the commercial black oxide employed in the process. To separate this impurity, evaporate to dryness, redissolve the residue in a little water, which leaves the calcium sulphate undissolved, and the pure solution of manganese sulphate is obtained by filtration. (*A. J. P.*, 1869.) Edo Claassen adds alcohol to the concentrated solution to promote crystallization. (*Ph. Rund.*, 1887.)

Properties.—Manganese sulphate has the formula $MnSO_4$, in which the dyad metal manganese replaces the H_2 of H_2SO_4 . From its aqueous solution it crystallizes in rhombic prisms, which contain variable proportions of water of crystallization according to the temperature of the solution and other circumstances. Obtained by evaporation at a gentle heat, they contain four molecules of water; between 45° and 68° , five molecules; under 42° , seven molecules; and a concentrated solution, mixed with sulphuric acid, and evaporated, yields granular crystals with one molecule. Heated to 240° , these crystals lose three molecules of water, and at a red heat become anhydrous. (Brande and Taylor.) The crystals usually have a pale-rose or pink color. The salt has an astringent and bitterish taste. It is very soluble in water, but its solubility varies with its water of crystallization. When anhydrous, it is dissolved by two parts of water at 15.5° C. (60° F.), and in its own weight at 100° C. (212° F.). If carelessly prepared, it is likely to contain copper and arsenic, as well as iron. As it is the source of nearly all the preparations of manganese, it is of importance that it should be pure; hence the sulphate, as first obtained, should be calcined at a low red heat at least twice, to render the contaminating metals insoluble, and then tested in solution, to be sure of its purity. According to A. Görgen, copper and iron, as well as nickel and cobalt, are completely precipitated by manganese sulphide. In applying this reagent, the impure solution is shaken for about a quarter of an hour with the sulphide, and then boiled for a few minutes. The description of it in the U. S. Pharmacopœia is as follows:

"Colorless, or pale rose-colored, translucent, tetragonal prisms (crystallized at a temperature between 20° and 30° C. (68° and 86° F.), and containing 4 molecules, or 32.29 per cent. of water of crystallization); odorless, and having a slightly bitter and astringent taste. Slightly efflorescent in the air. Soluble in about 0.7 part of water at 25° C. (77° F.), and in 0.53 part of boiling water; insoluble in alcohol. The aqueous solution (1 in 20) is neutral or very slightly acid to litmus paper, and yields, with ammonium sulphide T.S., a

salmon-colored precipitate soluble in dilute acids; with potassium ferrocyanide T.S., a reddish-white precipitate; and with potassium ferricyanide T.S., a brown precipitate. With barium chloride T.S., it yields a white precipitate insoluble in hydrochloric acid. If a fragment of Manganese Sulphate be mixed with a little sodium hydroxide and the mixture fused, it will yield a dark green mass, dissolving in water with a green color. The aqueous solution of the salt (1 in 20), to which a few drops of hydrochloric acid and a few drops of chlorine water have been added, should, after having been boiled, not be colored red by potassium sulphocyanate T.S. (absence of iron). Another portion of the solution should not respond to the Time-Limit Test for heavy metals, omitting the addition of ammonia water (see PART III, Test No. 121). If the manganese be completely precipitated from an aqueous solution of 3 Gm. of the salt by the addition of ammonium carbonate T.S., the filtrate, on evaporation and gentle ignition, should leave no weighable residue (absence of salts of the alkalies, and of magnesium). A solution of 1 Gm., each, of the salt, and of sodium acetate, in 10 Cc. of water, to which a few drops of acetic acid have been added, should not be affected by hydrogen sulphide T.S. (absence of zinc). If 1 Gm. of the salt be gently ignited, in a porcelain crucible, it should lose not more than 0.323 Gm. of its weight (distinction from *Manganese Sulphate containing a larger amount of water of crystallization*)." U. S.

Uses.—At one time manganese sulphate was said to be an active cholagogue and purgative, but it has failed to come into use as such. According to Thomas Thomson of Glasgow, it resembles sodium sulphate both in taste and in effect, operating as a purgative in the dose of from one to two drachms (3.9 to 7.5 Gm.). From the circumstance that manganese had been found in small proportion in the blood, it was conjectured that this metal, like iron, might play an important part in the human economy, and trial was made of it in *anæmia*, as an adjuvant of the chalybeates, but the results have not been satisfactory and it is at present rarely given.

Dose, as a tonic, from five to twenty grains (0.32 to 1.3 Gm.).

Off. Prep.—Mangani Dioxidum Præcipitatum, U. S.

MANNA. U. S.

MANNA

(mân'na)

"The concrete saccharine exudation of *Fraxinus Ornus* Linné (Fam. *Oleaceæ*)." U. S.

Manne, *Fr. Cod.*; Manna, *P. G., It.*; Mana, *Sp.*

Manna is said to be obtained from several other trees besides *Fraxinus Ornus*, among which

F. rotundifolia, *F. excelsior*, and *F. parviflora* have been particularly designated. Many saccharine substances, generally exudations from plants, have, from their resemblance to this substance, obtained the name of manna, and attracted more or less attention from writers. They are described in a note.¹

¹ **False Mannas.**—An efflorescence of mannite is said to occur upon certain sea weeds upon exposure to the air. (*J. P. C.*, Avril, 1859.) The term "manna" has been applied to certain substances which have no relation to true manna, notably to the lichen *Lecanora esculenta*, which at times has suddenly fallen like rain over immense tracts of country, from Persia to the African Sahara. It occurs in the form of small roundish lumps, from the size of a pin's head to that of a pea, yellowish or grayish externally and whitish within, hard, inodorous, and insipid. It has been affirmed that this lichen does not contain starch, but it is really used as an article of food, and good bread is said to have been made out of it. (*Nature*, Jan. 1891.) It is probable that it is the manna of Scripture. A false manna produced in quantities on the old olive trees round about Mansourah is said to contain 52 per cent. of true mannite with 7.3 per cent. of reducing sugar. (*J. P.*, xlv. 289.)

The proper false mannas, exudations from various trees, are best considered under the headings of the countries which yield them:

European False Manna, or Briançon Manna, an exudation from the common European larch (*Larix europæa*, or *Pinus Larix*), differs chemically from ordinary manna in containing no mannite. Berthelot found in it a peculiar sugar, which he named *melastose*. (See *A. J. P.*, 1859, p. 61.) To this the formula $C_{12}H_{22}O_{11} + 2H_2O$ is given showing that it belongs to the class of the saccharides.

American False Manna.—A substance resembling manna, of a sweet, slightly bitter and terebinthinate taste, and actively purgative, exudes from incisions in *Pinus lambertiana*, of Oregon, and is used by the natives. (*Nar. of U. S. Eepl. Exped.*, v. 232.) Berthelot has extracted from this product a peculiar saccharine principle, which he calls *pinite*. It is very sweet, but does not undergo the vinous fermentation. (See *A. J. P.*, xxviii. 157.) Pinite was for a long time classed among the sugars, but the latest researches seem to show that it is a hexahydric phenol derived from hexahydrobenzene. The formula is $C_6H_4(OH)_6$, and it is a methyl derivative of inosite.

California Manna, or Father Picolo's Manna. Proust (*Ann. d. Chim.*, 1806, 145) alludes to manna mentioned by Father Picolo as being deposited on a species of grass in California. J. U. Lloyd (*A. J. P.*, 1897, 337) believes Picolo's manna to be a saccharine deposit, caused by aphides on *Phragmites communis*. It is apparently still collected by the Indians.

African False Mannas.—**Turkish Manna** is a sweet product obtained from *Echinops persica*, Fisch., and is obtained by treating the cocoons of a coleopterous insect (*Larinus maculatus*) with hot water, filtering and crystallizing the sugar. From it Berthelot obtained a new variety of sugar, *trehalose*, $C_{12}H_{22}O_{11} + 2H_2O$. (*Gaz. Méd. de Paris*, 1857.) **Pinus Cedrus**, of Mount Lebanon, yields a similar product, which has some repute in Syria as a remedy in phthisis. (*P. J.*, xlii. 411.) In the neighborhood of Diarbekir, in Asiatic Turkey, a saccharine substance, known as *Diarbekir manna*, is found on the leaves of dwarf oaks, from which it appears to be exuded. (*Ibid.*, Nov. 1862, p. 646.) The manna of the oak of Kurdistan, spoken of by Flückiger, is probably the same as that of Diarbekir, which may be its entrepôt. According to Flückiger, this consists chiefly (90 per cent.) of a crystallizable sugar. It deviates to the right the plane of polarized light, and reduces in the cold the solution of copper oxide in soda and glycerin. This manna contains a muilage, but no cane sugar or dextrin. (*J. P. C.*, Avril, 1873, p. 335.) *Quercus Villorea*, Kotschy, and *Q. persica*, Jaub. et Spach, yield "oak manna," through insect agency, while certain species of *Echinops* (probably *E. persica*, Fisch.) yield the singular manna-like substance that is known as *Trehala* in Syria and as *Shukkar Tigal* in India. *Pyrus glabra* yields a manna which is collected by the people of Luristan in Persia. It has long been known that *Salix fragilis* and probably other species of willow yield to the Persians a manna-like exudation. According to Raby (*L'Union Pharm.*, Mal. 1889), there are two varieties, *chirkhest* and *bîdenguêth*, which con-

Fraxinus Ornus, L., *Sp. Pl.* (1753) 1057; Willd., *Sp. Plant.* iv. 1104; B. & T. 170. *Ornus europæa*, Persoon, *Synops.* i. 9; Lindley, *Flor. Med.* 547; Carson, *Illustr. of Med. Bot.*, ii. 8, pl. 61.—The flowering ash¹ is a tree of moderate height, usually from twenty to twenty-five feet, very branching, with opposite, petiole, pinnate leaves, composed of three or four pairs of leaflets, and an odd one at the end. The leaflets are oval, acuminate, obtusely serrate, about an inch and a half in length, smooth, of a bright green color, and supported on short footstalks. The flowers are white, and usually

expand with the leaves. They grow in close panicles at the extremities of the young branches, and have a very short calyx with four teeth, and four linear-lanceolate petals.

Both *Fraxinus Ornus* and *Fraxinus rotundifolia* are natives of Sicily, Calabria, and Apulia, and both contribute to supply the manna of commerce. The former is cultivated in Sicily, yields manna after the eighth year, and continues to yield it for ten or twelve years, when it is usually cut down and young sprouts are allowed to grow up from the root. (Stettner, *A. Pharm.*, liii. 194.) During the hot months the juice exudes spontaneously from the bark, and concretes upon its surface, but, as the exudation is slow, it is customary to facilitate the process by making deep longitudinal incisions on one side of the trunk. In the following season these are repeated on the other side, and thus alternately for the whole period during which the tree yields manna, extending sometimes, it is said, to thirty or even forty years. Straw or chips are frequently placed so as to receive the juice, which concretes upon them. The manna varies in its character according to the mode of collection, the nature of the season, and the period of the year at which the exudation takes place. That procured in Sicily is said to be the best. Daniel Hanbury travelled through the old manna region, and satisfied himself that the collection of manna for commercial purposes is confined almost exclusively to Sicily. (*P. J.*, Nov. 1872, 421.) But a more recent writer (*Ibid.*, Nov. 1879) asserts that the manna trees are still cultivated in Calabria. For still later information on manna collection in Sicily, see notes by J. S. Ward. (*Ibid.*, 1893, 381.) For an interesting description of California mannas by J. U. Lloyd, particularly *Piccolo's manna*, see *A. J. P.*, 1897, 329.

In commerce three varieties are distinguishable:

1. **FLAKE MANNA**, or *manna camulata*, is the purest variety. It exudes spontaneously, or from incisions, during the hottest and driest weather in July and August. According to Stettner, it is furnished by the upper incisions upon the trunk, while the lower incisions yield the inferior varieties. It is in irregular, unequal pieces, often several inches long, resembling stalactites, rough, light, porous, brittle, whitish or yellowish-white, and frequently concave on the surface by which they were attached to the trunk, and which is often soiled by impurities, sometimes by adherent fragments of the bark. When broken, these pieces exhibit a crystalline or granular structure. This variety is sometimes in small fragments, generally less than an inch in length.

2. **COMMON MANNA**—the *manne en sorte* of French pharmacy—is next in quality, and is collected in September and the beginning of October, when the heat of the weather has begun to moderate. The juice does not now concrete so readily, and a portion, falling on the ground at the root of the tree, becomes more

tain respectively, according to the analysis of Ludwig, *chirchæstie* ($C_6H_{14}O_6$), allied to sorbite, and *videnguebinæ* ($C_{12}H_{22}O_{11}$), allied to melezitose. Whether these mannas are really distinct from those sold in the Indian bazaars as coming from Afghanistan and Persia seems uncertain. Of these bazaar mannas the most important is the *Shirkoti* or *Oriental manna*. By Haussknecht it is referred to *Atraphaxis spinosa*; but J. E. T. Aitchison states that it is yielded by the *Cotoneaster nummularia*, Fisch. et Mey., a tall, stout shrub, whose smaller branches in July become covered with an exudation, which is eaten as a sweetmeat, and exported in quantity to Russia and India. The second variety, *Taranjabin*, is yielded by the camelthorn, *Alhagi Camelorum*, Fisch., in Persia and Afghanistan, and probably by *Alhagi Maurorum* of De Candolle, a leguminous thorny shrub abundant in India,—if indeed the two species be distinct. According to A. Villiers, it is nearly pure melezitose. (*P. J.*, 3d ser., vii. 917.) A third kind of manna is *Gazanjabin*, or *Gazanjabin*, yielded by *Tamarix gallica*, Linn., var. *mannifera*, a fourth kind is obtained from the *Salsola fatida*, DC. (*P. J.*, Dec. 11, 1886, 467.) The *tamarisk* of Northern Africa (*Tamarix gallica*, Ehrh.), which produces the small *tamarisk galls* of Mogador, containing 40 per cent. of tannic acid (*A. J. P.*, 1878, p. 27; also *N. R.*, 1877, p. 41), according to Burckhardt also gives origin to a species of manna that is used by the Bedouin Arabs near Mount Sinai with their food. This substance, however, according to Mitscherlich, contains no mannite, but consists wholly of muclaginous sugar. Berthelot found a manna from Sinai to consist of 55 per cent. of cane sugar, 25 of levulose and glucose, and 20 of dextrin and analogous substances. (*Ann. Ch. Phys.*, lxxv.)

Persian Manna, or *Gez*, has been identified (*O. D.*, 1894, 790) as being derived from *Astragalus anisacanthus*, and is found in the districts of Khonsar, Feridan and Chahar Mahal, and Isfahan. In the form of sweetmeat, having the appearance of flour, it is sent all over Persia and much esteemed.

Australian Mannas.—A manna-like exudation on the *Eucalyptus viminalis*, Labill., growing in New South Wales, contains a saccharine matter called *melitose*, different in properties from mannite and from all the varieties of sugar, though isomeric with glucose. It is susceptible of the vinous fermentation. (See *A. J. P.*, xxviii. 157.) *Lerp* is produced upon the leaves of *Eucalyptus dumosa*, when very small, and sometimes appears spread over large extents of country like a kind of snow. The natives use it for food. It is a complex body, containing an unfermentable sugar, *eucalin*, gum, starch, inulin, and lignin. (*J. P. C.*, xvi. 240.) It is said to be a secretion from an insect, formed into minute cells, each of which is the abode of one of the insects. (See *A. J. P.*, 1862, p. 547.) *Myoporum platycarpum*, R. Br., the sandalwood- or dogwood-tree of Australia, exudes an exceedingly sweet and pleasant manna, which is much used as an article of food. F. W. Passmore obtained from *Eucalyptus Gunnii*, Hook., a sugar termed *melitriose*. (*P. J.*, 1891, 718.)

New South Wales Manna.—According to R. T. Baker (*Journ. and Proc. Roy. Soc. New South Wales*, xxx. 1897), this manna is produced in the form of nodules at the nodes of the stems of the blue grass *Andropogon annulatus*. It contains numerous crystals of mannite, amounting, according to the analysis of H. G. Smith, to 50 per cent.

¹ A syrup prepared from the inner bark of this tree has been employed in Europe by Devergie, with supposed advantage, in chronic *eczema* and *impetigo*. The bark contains much tannin, and a muclaginous principle which renders diluted alcohol a better menstruum than boiling water. (*J. P. C.*, 3e sér., ix. 347.)

or less mixed with impurities, and forms imperfectly solid masses, which require to be further dried in the sun. Common manna consists of whitish or yellowish fragments, similar to the pieces of flake manna, but much smaller, mixed with a soft, viscid, uncrystallized brownish matter, identical with fat manna.

3. **FAT MANNA** is collected in the latter part of October and November, when the weather is cooler and rains are more common. The juice is now still less disposed to concrete, and flowing down the trunk is received in a small excavation at its base. As found in commerce, it is in the form of a soft, viscous mass, containing few crystalline fragments, of a brown or yellowish-brown color, and full of impurities. The U. S. Pharmacopœia directs that such manna should be rejected.¹

Properties.—Manna is officially described as "in irregular, more or less elongated, flattish, 3-sided pieces; externally yellowish-white; friable, somewhat waxy; internally whitish, porous and crystalline; odor suggestive of maple sugar; taste sweet, slightly bitter and faintly acid. On heating 5 parts of Manna with 100 parts of alcohol to boiling, and filtering, the filtrate should rapidly deposit crystals of mannite." U. S. Manna has a slight, peculiar odor, and a sweet taste, which in the impure kinds is also very nauseous, but in the finest flake manna scarcely so much so as to be disagreeable. Its sp. gr. is 0.834. It melts with heat, and takes fire, burning with a blue flame. When pure it is soluble in three parts of cold and in its own weight of boiling water. From a boiling saturated aqueous solution it separates in partially crystalline masses on cooling. Alcohol also dissolves it. Boiling alcohol will dissolve 15 parts of manna, and upon cooling deposit beautiful crystals of mannite.

¹ **Fictitious Manna.**—Attempts have been made to counterfeit manna, but the facility of detection renders such frauds unprofitable, and they are not often practised. R. P. Thomas described (*A. J. P.*, xxiv.) a sophisticated manna which differed from the genuine drug both in sensible and in chemical properties, not even containing mannite. Baumé describes a method in which common manna is purified so as to resemble flake manna. It consists in dissolving common manna in a little water, allowing the liquid to settle, decanting it in order to separate the impurities, then inspissating it so that it will congeal on cooling, and immersing threads in the inspissated liquid, several times successively, in the manner practised by candle makers. It may be still further purified by the use of animal charcoal. Thus prepared, it contains less mannite than flake manna, and less of the nauseous principle, but is said not to operate less effectively as a laxative. A fictitious manna is described by Edmond Histed (*P. J.*, April, 1870) as having been taken from Paris to London, which bears a close resemblance to flake manna, for which it might be mistaken upon a hasty notice. The resemblance is, moreover, increased by the fact that it contains mannite, of which Histed obtained 40 per cent., while fine natural flake manna yielded him 70 per cent. Closely examined, it is found to differ essentially from genuine flake manna, showing no crystals of mannite when broken, not having the taste and smell characteristic of good manna, and, besides, being cleaner, lighter-colored, more solid, and making a clearer solution in water. (See *A. J. P.*, 1870.) May not this have been a specimen of artificial flake manna, prepared from the inferior or common manna?

Fourcroy and Vauquelin found manna to consist of—1, a peculiar sweet principle, *mannite*, which constitutes 75 per cent.; 2, a variety of sugar; 3, a yellow nauseous matter, upon which the purgative property is thought chiefly to depend; and, 4, a little mucilage. Leuchtweiss obtained from 105 parts of manna 11.6 of water, 0.4 of insoluble matter, 9.1 of sugar, 42.6 of mannite, 40.0 of a mixture of mucilaginous matter containing mannite, resin, organic acid, and a nitrogenous substance, and 1.3 of ashes. In *manna canellata in fragmentis* he found 37.6 per cent. of mannite, and in *manna Calabrina* 32 per cent. (*Pflanzenstoffe*, 2d ed., p. 180.) Buignet discovered in manna a considerable proportion of dextrin. He appears to have been led to this discovery by observing a very energetic dextrogyrate power in flake manna, which could not be owing to the saccharine matter it contained, because the same power continued after all the sugar had been destroyed by fermentation. Dextrin forms about one-fifth part of flake manna, and a much larger part of the inferior kinds. It may be readily obtained separate by triturating 200 parts of flake manna with 400 of alcohol at 70° F. in successive portions, filtering the resulting mixture, by which the mannite is left behind, and then separating the sugar and dextrin contained in the clear liquor. This is done by concentrating the liquor to a syrupy consistence, and adding about 10 parts of alcohol at 90° F. The mixture separates into two layers, the upper consisting of a strong alcoholic solution of sugar, the lower of a saturated solution of dextrin in weak alcohol. The latter is separated, washed repeatedly with alcohol at 90° F., and then, after dilution with water, decolorization, and filtration, is evaporated gently by a water bath until it ceases to lose weight. The substance remaining is dextrin. The saccharine matter of manna is a mixture of cane sugar and levulose, which are in such proportion as almost to neutralize their reciprocal optic properties. All the forms of commercial manna contain both sugar and dextrin, and, though the quantity of the two jointly varies considerably, yet their relative proportion is invariable, being 2 molecules of dextrin and 1 molecule of sugar. This is the same result that is reached in the saccharification of starch, and the inference is fair that the dextrin and sugar in manna are the result of a transformation of starch in the plant. (*J. P. C.*, Juillet, 1868.) It is owing to the presence of glucose and dextrin that manna is capable of fermenting. Flückiger found in all samples of mannite examined a small amount of a dextrogyrate mucilage, which is precipitated by neutral lead acetate, and yields mucic acid when boiled with strong nitric acid. The greenish color of certain pieces of manna is produced by *fraxin*, $C_{12}H_{12}O_{10}$, a glucoside closely resembling *asculin*. Fraxin crystallizes in colorless prisms, easily soluble in hot water and in alcohol, and has a faintly astringent and bitter taste. By diluted acids it is

resolved into *fraxetin*, $C_{10}H_{16}O_8$, and *glucose*, $C_6H_{12}O_6$. Even its diluted solutions are fluorescent. (*Pharmacographia*, 2d ed.)

Mannite (*mannitol*) is white, inodorous, crystallizable in semi-transparent needles, of a sweetish taste, soluble in five parts of cold water, scarcely soluble in cold alcohol, but readily dissolved by that liquid when hot, and deposited when it cools. Its composition is $C_6H_{14}O_6$, and it is considered as belonging to the class of *hexatomic alcohols*. If mixed with chalk and cream-cheese and kept for some weeks at the temperature of 40° C. (104° F.), it yields alcohol largely, with the disengagement of carbonic acid and hydrogen and the production of lactic acid. No fungus is produced, as in the ordinary fermentation of sugar. (Berthelot, *J. P. C.*, xxx.) With lime, barium and strontium oxides, it forms definite compounds, soluble in water, and precipitable from their aqueous solutions by alcohol. (*Ibid.*, Jan. 1860.) It does not reduce an alkaline solution of copper oxide; and a test of its purity is thus presented. (*A. J. P.*, Jan. 1861, p. 26.) Its optical activity can be observed only after the addition of borax. It is then found to be dextro-rotatory. Emil Fischer has shown that there are three mannites obtainable; the ordinary mannite is the dextro-rotatory variety, and is always obtained in the reduction of *a*-mannose with sodium amalgam; a lævo-rotatory variety is obtained by the reduction of *l*-mannose; and an inactive mannite is obtained from the inactive mannose. These three physical isomers differ slightly in their fusing points and crystalline form. The native variety may be obtained by boiling manna in alcohol, allowing the solution to cool, and redissolving the crystalline precipitate; pure mannite is now deposited. Another method is to dissolve flake manna in water, precipitate by solution of lead subacetate, filter, throw down the excess of lead by sulphuric acid, evaporate the solution, and mix with alcohol. On cooling, the mannite is deposited. (Bonsall, *A. Pharm.*, cxxxiv. 70.) This principle has been found in numerous vegetables. It is said to be gently laxative in the dose of from one to two ounces (31 to 62 Gm.).

Manna, when long kept, acquires a deeper color, softens, and ultimately deliquesces into a liquid, which on the addition of yeast, undergoes the vinous fermentation. This is probably owing to its conversion into sugar by the absorption of enough oxygen to cause it to pass over into some variety of glucose or fermentable sugar. That which is driest resists this change the longest. It is said that manna recently gathered is less purgative than it afterwards becomes.

Uses.—Manna is a gentle laxative, usually operating mildly, but in some cases producing flatulence and pain. It is usually prescribed with other purgatives, particularly senna, rhubarb, magnesia, and the neutral salts, the taste of which it conceals, while it adds to the purga-

tive effect. The *dose*, for children, is from one to four drachms (3.9 to 15.5 Gm.). It is usually given dissolved in water or some aromatic infusion; but the best flake manna may be administered in substance. Manna forms a combination with iron, which it preserves against oxidation. (See *P. J.*, March, 1873.)

Dose, half to one ounce (15.5 to 31 Gm.).

Off. Prep.—Infusum Sennæ Compositum, *U. S.*

MARRUBIUM. U. S.

MARRUBIUM [Hoarhound, Horehound]

(mar-rû-bi-ûm)

"The dried leaves and flowering tops of *Marrubium vulgare* Linné (Fam. *Labiatae*)."
U. S.

Herba Marrubii; Marrube blanc, *Fr. Cod.*; Andornkraut, Weisser Andorn, *G.*; Marrubio, *It.*, *Sp.*

Marrubium vulgare, L., *Sp. Pl.* (1753) 583; Willd., *Sp. Plant.* iii. 111; B. & T. 210.—*White Hoarhound* has a perennial fibrous root, and numerous annual stems, which are quadrangular, erect, very downy, and from twelve to eighteen inches high. The leaves are about an inch long, roundish-ovate, dentate or deeply serrate, obtuse, wrinkled, veined, downy above, hoary on the under surface, and supported in pairs on strong footstalks. The flowers are white, and in crowded axillary woolly whorls. The calyx is tubular, and divided at the margin into ten narrow segments, which are hooked at the end. The corolla is also tubular, whitish, with a labiate margin, of which the upper lid is bifid, the under reflected and three-cleft, with the middle segment broad and slightly scalloped; stamens four, included. The seeds are four, in the bottom of the calyx. The plant is a native of Europe, but has been naturalized in this country, where it grows on the roadsides, and flowers in July and August. The herb has a strong, rather agreeable odor, which is diminished by drying and lost by keeping. It is officially described as having "branches quadrangular, grayish-green, densely white-hairy; leaves opposite, petiolate, roundish-ovate, 1.5 to 5 Cm. long, obtuse, coarsely crenate, strongly rugose-veined, more or less white-hairy, especially underneath; flowers in dense axillary whorls, with a 10-toothed calyx, the divisions of which are slightly unequal, erect-spreading and pungent; corolla small, whitish, bilabiate; stamens four, included; fruit of four ovoid, obtuse, nearly smooth nutlets, about 1.5 Mm. long; odor distinct, rather agreeable; taste somewhat aromatic and bitter." *U. S.* The bitterness is extracted by water and alcohol. It contains a volatile oil, resin, tannin, lignin, and a bitter principle called *marrubiin* by Meisner. This marrubiin is slightly soluble in cold water, crystallizes from alcohol in prismatic and from ether in tabular crystals, is not precipitated by tannin, and has a very bitter and somewhat acrid taste. The fusing point of the crystals

is 160° C., according to Kromayer. Marrubiin was afterwards obtained by Harms (*A. Pharm.*, 116, 141), by Hertel (*A. J. P.*, June, 1890), and by Morrison (*Ibid.*, July, 1890). A more recent study was by Matusow (*Ibid.*, 1897, 201). He gives to it the formula $\text{C}_{40}\text{H}_{48}\text{O}_6$, and states the melting point of the purified substance to be from 154° to 155° C. According to him, it is not a glucoside.

Uses.—Hoarhound is tonic, in large doses laxative, and may be so given as to increase the secretion from the skin, and occasionally from the kidneys. It was formerly considered a valuable deobstruent, and was recommended in *chronic hepatitis, jaundice, amenorrhœa, phthisis*, and various *cachetic affections*. By its gently tonic powers it may have proved advantageous in some of these complaints, but it exerts no specific influence over any of them, and has passed mainly from the hands of physicians into domestic use. It is employed chiefly in *catarrh*, and in other *chronic affections of the lungs*, attended with cough and copious expectoration. The infusion, made in the proportion of an ounce of the herb to a pint of boiling water, may be given in wine-glassful doses.

Dose, thirty grains to a drachm (2.0 to 3.9 Gm.).

MASSA FERRI CARBONATIS. U. S.

MASS OF FERROUS CARBONATE [Vallet's Mass]

(mă'ssə fēr'ri cār-bō-năt'is)

Pilula Ferri Carbonatis, Br. 1885, also U. S. 1870; *Pilula Ferri Carbonici*, *Pilula Ferrata* Vallet; *Pill of Carbonate of Iron*, Vallet's *Ferruginous Pills*, Vallet's *Pill Mass*; *Pilules de Carbonate ferreux*, Fr. *Od.*; *Pilules ferrugineuses*, *Masse Pilulaire de Vallet*, Fr.; *Valletsche Pillen*, G.; *Pillule* di Vallet, It.

* "Ferrous Sulphate, in clear crystals, *one hundred grammes* [or 3 ounces av., 231 grains]; Monohydrated Sodium Carbonate, *forty-six grammes* [or 1 ounce av., 272 grains]; Clarified Honey, *thirty-eight grammes* [or 1 ounce av., 150 grains]; Sugar, in coarse powder, *twenty-five grammes* [or 386 grains]; Syrup, Distilled Water, each, *a sufficient quantity*, to make *one hundred grammes* [or 3 ounces av., 231 grains]. Dissolve the Ferrous Sulphate and the Monohydrated Sodium Carbonate, each separately, in *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of boiling Distilled Water, and, having added *twenty cubic centimeters* [or 325 minims] of Syrup to the solution of the Iron salt, filter both solutions, and allow them to become cold. Introduce the solution of Monohydrated Sodium Carbonate into a bottle having a capacity of about *five hundred cubic centimeters* [or 16 fluidounces, 435 minims], and gradually add the solution of the Iron salt, rotating the bottle constantly or frequently, until carbonic acid gas no longer escapes. Add a sufficient quantity of Distilled Water to fill the bottle; then cork it and

set it aside, so that the Ferrous Carbonate may subside. Pour off the supernatant liquid, and, having mixed Syrup and Distilled Water in the proportion of *one volume* of Syrup to *nineteen volumes* of Distilled Water, wash the precipitate with the mixture by decantation until the washings no longer have a saline taste. Drain the precipitate on a muslin strainer, and express as much of the Water as possible. Lastly, mix the precipitate at once with the Honey and Sugar, and, by means of a water-bath, evaporate the mixture in a tared dish, with constant stirring, until it is reduced to *one hundred grammes* [or 3 ounces av., 231 grains]." U. S.¹

The effect of saccharine matter in protecting iron from oxidation has been explained under the heads of *Ferri Carbonas Saccharatus* and *Syrupus Ferri Iodidi*. The U. S. mass of ferrous carbonate is another example of a ferruginous preparation in which the iron is protected from further oxidation by the same means. The process of the U. S. P. (8th Rev.) is nearly the same as that of the U. S. P. 1890, excepting that the monohydrated sodium carbonate has replaced the crystallized variety, and the quantity of the alkaline salt has been somewhat increased. The salts employed are the same as those used for obtaining the formerly official ferric subcarbonate, but in forming that preparation the carbonate which is at first precipitated absorbs oxygen, and loses nearly all its carbon dioxide in the processes of washing and drying. When, however, as in the U. S. formula above given, the reacting salts are dissolved in weak syrup instead of water, and the washing is performed with weak syrup also, the absorption of oxygen and loss of carbon dioxide during the separation of the precipitate are almost completely prevented. It only remains, therefore, to preserve it unaltered, and to bring it to the pilular consistence, and this is effected by admixture with honey and sugar, and evaporation by means of a water bath. It is essential to the success of this process that the ferrous sulphate should be pure, otherwise some ferric oxide will be present in the product. The process is that of Vallet of Paris, after whom the preparation is popularly called. The present U. S. process differs from that of 1870 in omitting to direct

¹ Wm. Silver Thompson states that the mass is more stable when made by the following formula than when prepared in the official manner. Take of Ferrous Sulphate eight ounces; Sodium Bicarbonate six ounces; Sugar, in fine powder, four and a half ounces; Clarified Honey half an ounce; Syrup, Water, each, a sufficient quantity. Dissolve each salt separately in water, add the sodium solution to the iron solution gradually, constantly stirring until the effervescence ceases, then add about a fluidounce of syrup, and again stir. After the carbonate has subsided, draw off the supernatant liquid, and repeat the washing with cold water slightly sweetened with syrup, until the washings are free from a saline taste; when, having again drawn off the supernatant liquid, transfer the precipitate to a muslin cloth, and express as much of the water as possible. To the precipitate, in a porcelain dish placed over a water bath, add the honey and sugar, and with frequent stirring evaporate to the pilular consistence. (*A. J. P.*, 1870, p. 30.)

boiled water for washing the precipitated ferrous carbonate. This is an important omission, because there is likely to be some oxidation of the salt, due to the air in the water. The British Pharmacopœia 1898 omitted Vallet's mass. (See *Ferri Carbonas Saccharatus*.) Gonnermann prepares *powdered Vallet's mass* by mixing intimately ten parts of milk sugar and five parts of powdered licorice root with sufficient freshly precipitated ferrous carbonate to make, when dried, thirty-five parts, and adding enough powdered licorice root to make the whole weigh forty parts. (*Ph. Post*, 1893, 238.)

Properties.—The U. S. preparation is in the form of a soft pilular mass, of a dark greenish-gray color, becoming black on exposure, and with a strong ferruginous taste. When carefully prepared, it is wholly and readily soluble in acids. It contains nearly half its weight of ferrous carbonate. The corresponding pill, obtained from the saccharine carbonate, may be supposed to contain one-third of ferruginous matter.

Uses.—The U. S. mass of ferrous carbonate, or Vallet's ferruginous mass, is an excellent preparation for use in simple *anæmia* and *chlorosis*. Its chief merits are its unchangeableness, its freedom from astringency, and its ready solubility in acids.

Dose, in pills, from three to five grains (0.20 to 0.32 Gm.), after meals.

MASSA HYDRARGYRI. U. S. (Br.)

MASS OF MERCURY [Blue Mass]

(mäs'sä hÿ-drär'gy-ri)

Pilula Hydrargyri, *Br.*; Mercury Pill; **Pilulæ Hydrargyri**, *U. S.* 1870; **Pilulæ Cæruleæ**, *Massa Cærulea*; **Blue Pills**, *Pills of Mercury*; **Mercurial Pill**; **Pilules mercurielles simples**, *Fr. Cod.*; **Pilule de Mercure**, *Pilules bleues*, *Fr.*; **Mercurialpillenmasse**, *G.*

* "Mercury, *thirty-three grammes* [or 1 ounce av., 72 grains]; Glycyrrhiza, in No. 60 powder, *ten grammes* [or 154 grains]; Althæa, in No. 60 powder, *fifteen grammes* [or 231 grains]; Glycerin, *nine grammes* [or 139 grains]; Honey of Rose, *thirty-three grammes* [or 1 ounce av., 72 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Triturate the Mercury with the Honey of Rose until it is extinguished and globules of Mercury are no longer visible under a lens magnifying at least ten diameters. Add the Glycerin, then the Glycyrrhiza and Althæa gradually, and continue the trituration until the mass is homogeneous. Keep the product in well closed containers." *U. S.*

"Mercury, 2 ounces (Imperial) or 40 grammes; Confection of Roses, 3 ounces (Imp.) or 60 grammes; Liquorice Root, in fine powder, 1 ounce (Imp.) or 20 grammes. Rub the Mercury with the Confection of Roses until metallic globules are no longer visible; add the Liquorice Root; beat together until thoroughly mixed." *Br.*

The mercury constitutes one-third of the mass. The ingredients for this mass do not differ essentially from those of the U. S. 1880 formula. The U. S. process is well suited for the needs of the pharmacist, as the mass can be made with ordinary apparatus extemporaneously.

The proportion of glycerin, in the formula of the U. S. (8th Rev.), has been slightly increased, and this modification overcomes the tendency to harden slowly and become unfitted for use which was characteristic of the U. S. 1890 preparation.

The precise condition of the mercury in this preparation is somewhat uncertain. By far the greater proportion is in a state of minute mechanical division, and not chemically altered. Some maintain that the whole of the metal is in this state, others, that a small portion is converted during the trituration into mercurous oxide, and that this is the ingredient upon which the activity of the pill depends. The supposed oxidation is attributed partly to the influence of the air upon the surface of the metal, greatly extended by the separation of its particles, partly to the action of the substance used in the trituration. If the mercury is not oxidized during the trituration, there can be little doubt that it becomes so, to a slight extent, by subsequent exposure. The obvious changes which the mass undergoes by time can be explained in no other way, and mercurous oxide is asserted to have been actually extracted from old mercurial pill. Harold Senier analyzed a number of samples of blue mass, with the view of determining the amount of metallic mercury and of mercurous and mercuric oxides. The results showed that the latter gradually increased in quantity with the age of the blue mass, which, 18 hours after preparation, contained but a trace of mercurous oxide; after three months, 0.24 per cent. of mercuric and 0.62 per cent. of mercurous oxides were obtained, and in another sample, 0.44 and 1.60 per cent. respectively. After two years, 1.80 per cent. of mercuric and 4.22 per cent. of mercurous oxides were present. (*P. J.*, 1876.) Nevertheless, it scarcely admits of dispute that the metal, independently of oxidation out of the body, is capable of producing the peculiar mercurial effects when introduced into the stomach, probably undergoing chemical changes there. The U. S. P. provides a test which limits the quantity of mercurous oxide and proves the absence of mercuric oxide; it will be difficult for the ordinary "blue mass" of commerce to withstand these requirements: "If a portion of the Mass be triturated in a mortar, with warm acetic acid, the filtrate should not become more than slightly opalescent on the addition of a few drops of hydrochloric acid (limit of mercurous oxide). If another portion of the Mass be digested with warm, diluted hydrochloric acid and a little purified animal charcoal, the filtrate should not be affected by hy-

drogen sulphide T.S., or by stannous chloride T.S. (absence of *mercuric oxide*).” *U. S.* According to Mialhe, mercury is slowly converted into corrosive sublimate in the stomach, under the combined agency of air and sodium chloride. All agree that the efficacy of the preparation is proportionate to the extinction of the mercury; in other words, to the degree in which the metallic globules disappear. This extinction may be effected by trituration with various substances, and manna, syrup, honey, licorice, mucilage, soap, guaiac, and extract of taraxacum have been recommended, among others, for this purpose; but the confection or honey of rose has been adopted by the Pharmacopœias, as less open to objection than any others. The mercury is known to be completely extinguished when, upon rubbing a portion of the mass with the end of the finger upon a piece of paper, no globules appear, or the extinguishment may be more accurately judged by the official microscopic test. Powdered licorice root and powdered marshmallow root are added in order to give due consistence to the mass. The process now official was proposed by C. Lewis Diehl, and since the increase in the quantity of glycerin is very satisfactory. It is possible for the apothecary to make moderate quantities extemporaneously with no other appliances than the mortar and pestle. As the trituration requires to be long continued, which renders the process very laborious when conducted on the large scale, it is customary to prepare the mass by machinery. At Apothecaries’ Hall, in London, the trituration is effected by the agency of steam. The machine there employed consists of “a circular iron trough for the reception of the materials, in which revolve four wooden cylinders, having also a motion on their axes.” A machine for preparing blue mass, capable of being worked by hand or steam power, was invented by J. W. W. Gordon of Baltimore, and, having been found to answer well, was at one time in extensive use. (*A. J. P.*, xxi. 6.) We have referred, under *Hydrargyrum cum Creta* (page 638), to another ingenious apparatus, invented by Squibb, by which the extinguishment of mercury is very satisfactorily effected. Formerly much of the blue mass used in this country was imported, but at present the market is chiefly supplied by our own manufacturers. The preparation slowly changes color upon being kept, assuming an olive and sometimes even a reddish tint, in consequence, probably, of the further oxidation of the mercury.¹

¹ Blue mass frequently contains less than the due proportion of mercury. The fraud may be detected by the following plan, suggested by Reid of New York, and modified by a committee of the Philadelphia College of Pharmacy.

A certain weight of the mercurial mass, say fifteen grains, is mixed with about one-fourth of its weight of iron filings, and introduced into a small green glass bulb, at the end of a somewhat curved tube, the open extremity of which is inserted, through a cork into alcohol, contained in a broad-mouthed glass vial; another tube, open at both ends, passing through the cork, in order to permit the escape of

uncondensed gases. Heat is then applied to the bulb by means of a spirit lamp, is gradually increased until the glass becomes red hot, and continued for an hour. The alcohol in the vial dissolves the empyreumatic products, and, by being allowed to rise in the tube, and then expelled, serves to wash out any mercury that may be condensed upon its sides. The alcohol is poured off from the condensed mercury, which is then washed with fresh alcohol, dried, and weighed. (See *A. J. P.*, xviii.)

In consideration of the incomplete extinguishment of the mercury in many specimens of the blue pill, arising from the tedious process employed, F. B. Bengner proposes to obtain the metal in a state of minute division. For this purpose he adds to a solution of an ounce of stannous chloride, in a mixture of two drachms of hydrochloric acid and two ounces of cold water, a boiling hot solution of 136 grains of corrosive sublimate in four ounces of distilled water, and stirs the mixture for a few seconds. The mercury of the corrosive chloride is thrown down in the form of a black powder, to which, after the liquid has been drawn off by means of a pipette, 30 grains of sugar, 100 grains of powdered licorice, and about a drachm of glycerin are added. The mass, being transferred to a porcelain slab, is allowed to become sufficiently dry, and then mixed with enough glycerin and licorice to make it weigh 300 grains. (*P. J.*, ii. 165.) Theoretically, this appears to be a good process, but only a long experience of its practical advantages would justify its substitution for a plan which has been followed for so many years with results, upon the whole, so satisfactory. An obvious objection to the process is the possibility, with carelessness of manipulation, of having in the preparation a minute proportion of corrosive sublimate or stannous chloride.

The blue pill is sometimes wanted in the state of powder, but, from its peculiar constitution, it is not eligible for reduction to this form, as the mercury is disposed to aggregate during pulverization, and, from the honey it contains, it is likely, when pulverized, to attract moisture from the air. Chas. Bullock recommended the following method of preparing a powder which, as nearly as possible, represents the blue pill, in reference to its therapeutic effects:

Powdered Blue Mass.—Take of finely powdered Elm bark, finely powdered Sugar, and Mercury, equal parts, and of Alcohol a sufficiency. Rub the mercury with the powdered bark, adding from time to time enough alcohol to maintain a pasty consistence, until the mercury is completely extinguished; then spread the mass on paper to dry. When dry, powder it, add the sugar, and rub the mixture thoroughly until the powder will pass through a sieve of fine bolting cloth. (*A. J. P.*, 1859, p. 271.)

Uses.—This mass is among the mildest of the mercurials, being less liable than most others to act upon the bowels, and exercising the peculiar influence of the remedy upon the

uncondensed gases. Heat is then applied to the bulb by means of a spirit lamp, is gradually increased until the glass becomes red hot, and continued for an hour. The alcohol in the vial dissolves the empyreumatic products, and, by being allowed to rise in the tube, and then expelled, serves to wash out any mercury that may be condensed upon its sides. The alcohol is poured off from the condensed mercury, which is then washed with fresh alcohol, dried, and weighed. (See *A. J. P.*, xviii.)

system with less irritation. It is much employed for producing the sialagogue and alterative action of mercury, in doses of one to three grains (0.065 to 0.20 Gm.), guarded with opium if it disturbs the bowels. With a view to the alterative effect upon the digestive organs, three grains (0.20 Gm.) may be given every night, or every other night, for a time, and followed in the morning, if the bowels should not be opened, by a small dose of laxative medicine.

Dose, as a laxative, from five to fifteen grains (0.32 to 1.0 Gm.). It may also be used as a cholagogue cathartic combined with or speedily followed by a more certain purgative.

MASTICHE. U. S.

MASTIC

(mäs'tj-chē)

"A concrete resinous exudation from *Pistacia Lentiscus* Linné (Fam. *Anacardiaceæ*)." U. S.

Mastich; Mastix; Mastic, *Fr. Cod.*; Resina Mastiche, *G.*; Almaciga, Mastic, *Sp.*; Sakes, *Turk.*; Arah, *Arab.*

Pistacia Lentiscus, L., *Sp. Pl.* (1753) 1026; Willd., *Sp. Plant.* iv. 753; B. & T. 68.—The *lentisk* is a shrub or small tree, seldom more than twelve feet in height, much branched towards the top, and furnished with petiolate, abruptly pinnate leaves. The leaflets are from eight to twelve, and usually alternate, with the exception of the two upper, which are opposite. They are ovate-lanceolate, entire, obtuse, often mucronate, and sessile upon the common foot-stalk, which has a narrow foliaceous expansion on each side. The flowers are diœcious, and very small. The male are in an axillary ament; the female are arranged alternately upon a common peduncle, which is also axillary. The tree is a native of the countries bordering upon the Mediterranean. The fruit yields by expression a fixed oil, of a deep green color, and liquid at about 90° F., which the Arabs of North Africa use both as an article of diet and for light. A resinous exudation from the stem and branches is the official part, but it does not appear to be collected in all places where the tree flourishes. Under the name of *Bombay mastic* there occur in India masses of oleoresin said to be derived from the *Pistacia Terebinthus*, having the general appearance of true mastic with a deeper color, but lacking fragrance, and dissolving in hot alcohol. For an account of the collection of mastic from *P. Terebinthus* growing in the island of Cyprus, see *C. D.*, 1897, 273.

Mastic is obtained chiefly from the island of Seio, or Chios, in the Grecian Archipelago, where the tree is cultivated for this product. Incisions¹ are made in the trunk and principal

branches, from which the juice slowly exudes, and either hardens in tears upon the bark, or drops on the ground, where it is received upon cloths or the bare earth, and concretes in irregular masses. The tears are most esteemed, and are the only form recognized by the U. S. P. They are of various sizes, oval or roundish, often compressed, smooth, semi-transparent, of a pale-yellow color, of a shining fracture, friable, and usually covered with a whitish powder, occasioned by their friction against each other. They are brittle, but become plastic when chewed. The masses consist of yellowish agglutinated tears, with others of a darker color and less translucent, and often fragments of wood, bark, or earthy matter intermingled.

It is officially described as "in subglobular, lenticular, elongated or pear-shaped tears, about 3 Mm. in diameter, pale yellow or greenish-yellow, transparent, having a glass-like lustre, the surface sometimes very slightly dusty; brittle, becoming plastic when chewed; odor slight, balsamic; taste mild, terebinthinate. Mastic is completely soluble in ether and almost completely soluble in alcohol. The acid number should not be less than 65 (see PART III, Test No. 98)." U. S.

Mastic is nearly inodorous, unless rubbed or heated, when it becomes fragrant. Its taste is weak, but agreeably terebinthinate, and, after long chewing, very slightly acrid. It is at first friable under the teeth, but soon becomes soft and ductile, and acquires a white opaque appearance. Its sp. gr. is 1.074. It is fusible and inflammable by heat. Alcohol dissolves about 90 per cent. of it, leaving a viscid substance which becomes brittle when dried, and for which the name of *masticin* or *beta-resin of mastiche* has been proposed. This substance, though not dissolved by alcohol, softens and swells up in it, as gluten does in water. Hlasiwetz gives $C_{20}H_{31}O$ as the formula of the resin. The portion dissolved by the alcohol is called by Johnston *alpha resin of mastiche* or *masticic acid* because of its acid properties, and has the formula $C_{20}H_{32}O_2$. (*Handwörterbuch der Chemie*, iv. p. 280.) Mastic is wholly soluble in ether, chloroform, and oil of turpentine, scarcely soluble in the fixed oils, and insoluble in water. It consists chiefly of resin, with *masticin*, and a volatile oil, which can scarcely be said to have been obtained in a separate state, though it imparts flavor to alcohol and water distilled from the mastic, especially when this has been previously triturated with an equal weight of potassium carbonate. Flückiger, through Schimmel & Co., of Leipsic, ascertained that this volatile oil is present in mastic to the extent of 2 per cent.

comes from longitudinal incisions in the stem, made with a knife, close together, and extending from the root to the branches. In fifteen or twenty days the resin has concreted, and is collected in little pan-niers of white paper or cotton cloth. (*J. P. C.*, Nov. Déc., 1870, 359. See also *C. D.*, 1897, 273; also *Proc. A. Ph. A.*, 1897, 563.)

¹ According to J. Léon Soubelran the valuable tears are produced by spontaneous exudation from the branches. But the greater part of the resin

He found it to be a terpene of the composition $C_{10}H_{18}$. Schimmel & Co. (*Schim. Rep.*, April, 1897) state that mastic resin yields from 0.9 to 2.5 per cent. of a powerful balsamic essential oil of the same odor as the raw material, a sp. gr. of from 0.855 to 0.87 at 15° C., and an optical rotation (100-Mm. tube) of from +22° to +27°. Henry C. C. Maisch proposed a method of testing mastic (*A. J. P.*, 1901, 171) and Tschirch and Reutter (*A. Pharm.*, 1904, 104) examined mastic carefully; they found approximately 42 per cent. of free resin acids, of which 4 per cent. are soluble in 1 per cent. ammonium carbonate solution and 38 per cent. in 1 per cent. soda solution. The former are the isomeric α - and β -masticinic acids, $C_{22}H_{38}O_4$, the latter masticolic acid, $C_{22}H_{38}O_4$ (slight amount), amorphous α -masticonic acid, $C_{22}H_{38}O_4$ (20 per cent.), and β -masticonic acid, $C_{22}H_{38}O_4$ (18 per cent.). Besides this, mastic contains 30 per cent. α -masticoresen, $C_{25}H_{40}O_4$, soluble in alcohol; 20 per cent. of β -masticoresen (masticin), insoluble in alcohol, and 2 per cent. of an ethereal oil, possessing a pale yellow color and a somewhat camphoraceous odor. Finally, there is also a bitter principle, which could not be isolated in pure form. Mastic is occasionally adulterated with olibanum, sandarach, and other resinous bodies, and, in seasons of scarcity, with sea salt.

Uses.—Mastic was formerly thought to possess properties analogous to those of the turpentine, and was used in *debility of the stomach, hæmoptysis* from ulcerations, *leucorrhæa, chronic diarrhæa*, etc.; but its virtues were overrated, and it is at present scarcely ever given internally. In the East, however, an aqueous infusion is said to be still used in infantile *cholera*, and the Greeks employ cataplasms made by mixing it with bread and red wine, which they apply to the lower abdomen. (Landerer.) It is sometimes employed to fill the cavities of carious teeth, for which purpose it is well fitted by its softness. Great quantities of it are consumed in Turkey, where it is habitually chewed by the women, under the impression that it sweetens the breath and preserves the gums and teeth. The alcoholic solution has been employed as a styptic in *bleeding from the nose, leech bites*, etc., being applied by means of a camel's-hair pencil directly to the bleeding vessel. Dissolved in alcohol or oil of turpentine, it forms a brilliant varnish. A solution made by macerating half an ounce of mastic and fifteen grains of caoutchouc in two fluid-ounces of chloroform, and filtering in close vessels, forms a valuable *microscopic varnish*. The following mode of applying it to carious teeth has been recommended. Dissolve four parts of mastic in one of ether, in a bottle well stoppered. With the solution thus formed, which is yellow and of an oily consistence, saturate a small piece of cotton of the size of the carious cavity, and, having well cleansed and dried the cavity, introduce the cotton, without painful pressure, so as to fill it exactly. The resin

attaches itself to the diseased surface of the tooth, which it protects from the air, and from the food taken into the mouth.

Dose, thirty grains (2 Gm.).

Off. Prep.—*Pilulæ Aloes et Mastiches*, *U. S.*

MATICO. U. S.

MATICO

(măt'i-cō)

"The leaves of *Piper angustifolium* Ruiz and Pavon (Fam. *Piperaceæ*)." *U. S.*

Matico leaves; Feuilles de Matico, *Fr. Cod.*; Matico-blätter, *G.*

The genus *Piper*, according to Engler and Prantl, includes nearly six hundred species, which are distributed throughout the tropics of the Old and New World, being particularly numerous in tropical America and of relatively less number in Africa.

Piper angustifolium, Ruiz and Pavon, *Flor. Peruv.*—*Piper elongatum*, Vahl.—*Artanthe elongata*, Miquel.—This is a shrub with a jointed stem about twelve feet in height. In a dried specimen received from Ruschenberger, of the U. S. Navy, the leaves were sessile or very shortly petiolate, oval-lanceolate, acuminate, from two to six inches long by about an inch in breadth, bright green on the upper surface, paler and downy beneath, finely crenate, tessellated above, reticulate beneath, the meshes small, and the veins densely brownish hairy; of an agreeable aromatic odor and a strong spicy taste. The spikes are solitary, opposite the leaves, and cylindrical. The bracts are peltate or cucullate; the flowers hermaphrodite. The plant is a native of Peru, where the fruit, under the name of *thoho-thoho*, is employed in the same manner as cubeb. This species is also found in other parts of South America. The commercial drug matico is furnished, according to G. Dethan and R. Bertault (*J. P. C.*, 1897, 537), by two varieties of *Piper angustifolium*,—viz., *α-cordulatum* (*Artanthe elongata*, Miquel), and *β-ossanum*, which differ somewhat in the shape of the leaves. The former has the leaves larger, shorter, and broader, with an oblique cordate base. The midrib of *α-cordulatum* is much less convex below than in the other variety. In 1864 Bentley (*P. J.*, Jan. 1864) described a *false matico* from Central America believed to be yielded by the *Piper aduncum*, L. It is distinguished by the want of the reticulations on the upper and the down on the under surface which characterize true matico.

Properties.—The leaves, spikes, and stalks are mixed together, and more or less compressed, in the packages of the imported drug, and are all possessed of activity, though the leaves only are recognized by the Pharmacopœias. They are officially described as "from 10 to 15 Cm. long, short-petiolate, oblong-lanceolate; apex pointed, base unequally heart-shaped, margin very finely crenulate; tessellated above,

reticulate beneath, the meshes small, and the veins densely brownish-hairy; aromatic, spicy, bitterish, and astringent." *U. S.* Matico leaves are readily pulverized, forming a light-greenish, absorbent powder. The *maticin* of Hodges (*Philos. Mag.*, Sept. 1844) was found by Wiegand to be a salt of potassium. John J. Stell, who examined the drug in the expectation of discovering a principle analogous to cubebin or piperin, failed in the attempt. Flückiger found it to contain 2.7 per cent. of the volatile oil, which was slightly dextrogyrate and boiling in large part at 180° to 200° C. (356° to 392° F.). In the winter-time it deposited large crystals of a camphor fusing at 103° C. (217.4° F.), and having the odor and taste of the oil. The crystals have the formula $C_{12}H_{20}O$ according to Schimmel & Co. (*Schim. Rep.*, Oct. 1898, p. 37.) Kugler (*A. J. P.*, 1884, 477) and Thoms (*A. J. P.*, 1904, p. 584) state that the newer matico oils do not contain this camphor but contain *asarol* (propenyl-trimethyltrioxybenzene), $C_{12}H_{16}O_3$. Matico also affords, according to Marcotte, a crystallizable acid named *artanthic acid*, with some tannin. (*Pharmacographia*, 2d ed., p. 590.)

Uses.—Matico, on account of the presence in it of tannic acid, is feebly astringent and stimulant, acting much like cubeb upon the urinary passages. It is said to be employed in Peru in arresting *hemorrhages* and as a local application to *ulcers*, and has been used in European practice in the treatment of diseases of the genito-urinary organs such as those for which cubeb is commonly prescribed. It has also been praised as a remedy in *dysentery* and *diarrhœa* and especially as a local hæmostatic, in which it probably acts in part mechanically in the same manner as does agaric. The powder is sometimes used, but the fluid-extract is preferable for internal administration.

Dose, forty-five to seventy-five grains (3 to 5 Gm.).

Off. Prep.—Fluidextractum Matico, *U. S.*

MATRICARIA. *U. S.*

MATRICARIA [German Chamomile]

(măt-rî-că-rî-ă)

"The dried flower-heads of *Matricaria Chamomilla* Linné (Fam. *Compositæ*)."*U. S.*

Flores Chamomillæ Vulgaris; Wild Chamomile, Horse Gowan, Dog's Camovynne; Camomille commune (d'Allemagne), *Fr. Cod.*; Flores Chamomillæ, *P. G.*; Kamillen, Kamillenblumen, *G.*; Camomilla comune, *It.*; Manzanilla (Flor de), *Sp.*

Matricaria Chamomilla, Linn., *Sp. Plant.* (1753) 91.—This is an annual plant, with a branching stem a foot or two in height, bearing alternate leaves about two inches long, the lower ones tripinnate, the upper bipinnate or simply pinnate, and all of them very green, and nearly or quite smooth. The leaflets are linear and

very small. The flower-heads appear singly at the ends of the stem and branches. They are about three-quarters of an inch in diameter, with the rays spreading. The bracts of the involucre are obtuse, green in the middle, and whitish, membranous, and translucent at the margin. The ray-florets are white, at first spreading, and ultimately reflected. The disk is of a deep yellow color, at first flat, but in the end convex, and in some cases somewhat conical.

The plant is a native of Europe, and is occasionally cultivated in our gardens. All parts of it are active, but the flowers only are official. These shrink in drying, so that they are scarcely half as large as in their recent state. Those found in commerce are imported from Germany. They are officially described as "about 6 or 8 Mm. broad, exclusive of the rays, with a flattish imbricated involucre, a conical, hollow, and naked receptacle, 10 to 20 white ligulate and reflexed pistillate ray-florets which are about 8 Mm. long, and numerous yellow, tubular, perfect disk-florets without pappus; odor somewhat disagreeably aromatic; taste strongly aromatic and bitter. The similar flower-heads of *Anthemis arvensis* Linné, and *Maruta Cotula* De Candolle (Fam. *Compositæ*), have conical, solid, and chaffy receptacles." *U. S.*

The dried flowers of *matricaria* are considerably smaller than those of common chamomile, and exhibit a larger proportion of the disk-florets compared with those of the ray. They have a strong, peculiar, rather unpleasant odor, and a disagreeable, bitter taste. Their active constituents are volatile oil and bitter extractive, which are readily taken up by water and alcohol. The oil, which is obtained by distillation with water, is thick, somewhat tenacious, of a fine deep blue color becoming green and brown by age, and almost opaque in mass. Though supposed by Gerhardt to be identical with the oil of chamomile (*Anthemis nobilis*), it has been shown to be distinct. (*P. J.*, Feb. 1862, p. 429.) It congeals at —4° F., has the sp. gr. 0.93, and contains a terpene, $C_{10}H_{16}$, and a colorless oil, $C_{10}H_{16}O$. *Schimmel & Co.'s Report* for April, 1897, states that the German chamomile oil contains a paraffin hydrocarbon, which was obtained as a snowy white solid melting at 53° to 54° C. The blue color is due to a volatile principle called *azulene* by Piesse, and *cærulein* by Gladstone and others. This, when distilled with potassium, yields a terpene, ($C_{10}H_{16}$)s, and with phosphoric oxide a hydrocarbon, $C_{10}H_{14}$. (Kachler, *Ber. d. Chem. Ges.*, iv. 36.)

Uses.—*Matricaria* is a mild tonic, very similar to chamomile in medicinal properties, and, like it, in very large doses an emetic. It is considered also in Europe to be antispasmodic and anthelmintic. It is much employed in Germany, but in this country scarcely at all, unless by German practitioners. It may be given for the same purposes and in the same manner as chamomile.

Dose, half an ounce (15.5 Gm.).

MEL. U. S.

HONEY

(mél)

"A saccharine secretion deposited in the honey-comb by the bee, *Apis mellifera* Linné." U. S.

Miel, *Fr. Cod.*; Mel, *P. G.*; Honig, *G.*; Miele, *It.*; Miel, *Sp.*

From the nectaries of various flowers the bee extracts a thin, aqueous fluid, nearly without flavor and insipidly sweet, sometimes known as *nectar*. As honey is made out of this substance it is very much affected by the character of the nectar, so that the nature of the plants which predominate in the vicinity of the hive is a matter of great importance to the bee culturist, not only in regard to the flavor of the honey which is yielded, but even to its freedom from poisonous qualities, cases having been reported from time to time of poisoning produced by the eating of honey which had not been tampered with after extraction from the hive. See *N. J. M. R.*, 1852, 46; "*Poisonous Honey*," by L. F. Keble, *Proc. A. Ph. A.*, 1896, 167; H. Bley, *Ph. Ztg.*, Nov. 1885. The latter states that *Datura Stramonium* and *Gelsemium* are for honey making especially dangerous plants. The nectar when taken in by the bee is chemically changed by secretions from glands in the head and thorax, levulose, dextrose, and rarely sucrose being formed. The finest honey is that which is allowed to drain from the comb. If obtained from hives that have never swarmed, it is called *virgin honey*. An inferior kind is procured by submitting the comb to pressure, and if heat be employed previous to expression, the product is still more impure.

In the recent state honey is fluid,¹ but on being kept it is apt to form a crystalline deposit, and

¹ *Propolis*.—This is a resinous substance, deposited by bees at the base of the hive, and in other parts which require protection from the outer air, of a nature entirely different from that of wax or honey, and supposed to be intended for the protection of the comb from injurious agencies. H. O. Hitchcock (*Chicago Med. Journ.*, 1867) considers it one of the best remedies in simple mucous *diarrhæa*, even when severe and attended with pain and vomiting. In many cases only a single dose is required. It appears to possess anodyne and soporific properties. He has found it also efficacious in *dysentery* in the early stages, but it has proved useless in the disease when fully established. In *chronic diarrhæa*, even of the kind contracted in camp and remarkable for its obstinacy, it has seemed to act like a charm. It is of a dark reddish or yellowish-brown color, of a shining fracture, an aromatic taste and odor, quite insoluble in water, nearly so in ether, but readily dissolved by alcohol and solution of potassium hydroxide. Hitchcock has used both a tincture and an alkaline solution; the former (two drachms of propolis and four fluidounces of alcohol) in doses of from thirty minims to a fluidrachm (1.8 to 3.75 Cc.); the latter (two drachms of the resin to a fluidrachm of solution of potassium hydroxide and four fluidounces of a menstruum consisting of equal parts of water and simple syrup) in the dose of half a fluidrachm (1.8 Cc.) after each stool.

Bee bread is the name given to a material found in some of the cells of the comb, consisting mainly of the pollen of plants. (*Chicago Med. Examiner*, Sept. 1865.) Jas. S. Whitmire found that in the dose

to be ultimately converted into a soft granular mass. In commerce it is found of every consistence, from that of a viscid liquid like thin syrup or oil, to that of lard or soft suet. Its color is sometimes white, but usually yellowish, and occasionally of a brownish or reddish tinge. It has a peculiar agreeable odor, varying somewhat with the flowers from which it was collected, and a very sweet, feebly aromatic taste, which is followed by a slight prickling or sense of acrimony in the fauces. Cold water dissolves it readily, alcohol with less facility. "A syrupy liquid of a light yellowish to yellowish-brown color, translucent when fresh, but gradually becoming opaque and crystalline, having a characteristic, aromatic odor, and a sweet, faintly acid taste. When recent Honey is diluted with twice its weight of water, the resulting liquid should be almost clear, not stringy, and should have a specific gravity not lower than 1.099 (corresponding to a specific gravity of 1.370 for the original Honey). When Honey is incinerated in small portions at a time in a platinum crucible, it should not leave more than 0.3 percent. of ash. Honey has a faintly acid reaction upon litmus paper, and is levogyrate. If 5 Gm. of Honey be dissolved in 20 Gm. of water, a clear or nearly clear solution will result, which should not be rendered more than faintly opalescent by a few drops of silver nitrate T.S. (limit of *chlorides*), or of barium chloride T.S. (limit of *sulphates*). If 2 Cc. of a filtered solution of the Honey (1 in 4) be placed in a test-tube 1 Cm. in diameter, and 1 Cc. of absolute alcohol be allowed to flow down the walls of the tube held in an inclined position, so as to form an overlying layer, this should remain clear, and the line of contact should not show more than barely noticeable opalescence, which soon disappears; a permanent milky zone should not be produced (absence of *starch sugar*). If 2 Cc. of pure concentrated sulphuric acid be placed in a test-tube of 1 Cm. diameter, and 0.5 Cc. of a solution of Honey (1 in 4) be allowed to flow upon it so as to form a distinct upper layer, no colored line of contact should show at once, and at the end of one hour the zone of contact should be at most yellowish or clear brown; a brownish color becoming nearly black at the end of half an hour should not develop (absence of *cane sugar*). On boiling 1 part of Honey with 5 parts of water, the resulting solution, when cold, should not be rendered blue or green on the addition of iodine T.S. (absence of *starch*)." U. S. It is essentially a strong aqueous solution of mixed dextrose and levulose, the mixture being improperly known

of a drachm (3.9 Gm.) three times a day it caused great increase of the urinary secretion. No disagreeable effects followed its use, except a slight flatulency and looseness of the bowels. It is entirely palatable and inoffensive to the stomach. (*A. J. P.*, 1866.)

Eucalyptus Honey, or *Black Honey*.—This honey, a detailed description of which may be found in U. S. D., 18th ed., appears to have been not a natural but a sophisticated article.

as "glucose," and amounting generally to from 70 to 80 per cent. According to Wm. A. Selser, who separated wax from honey on a large scale, the proportion of wax in the honey comb averages 1 per cent.; from 1500 pounds he obtained 14½ pounds of wax by actual experiment. (*A. J. P.*, 1904, 267.)

The analyses of pure, unadulterated honey, given in the following table, show the variations in its composition. They were made by J. Campbell Brown (*Analyst*, iii. 269).

The *honey sugar* may be obtained by treating granular honey with a small quantity of alcohol, which, when expressed, takes along with it the other ingredients, leaving the crystals nearly untouched. The same object may be attained by melting the honey, saturating its acid with calcium carbonate, filtering the liquid, then setting it aside to crystallize, and washing the crystals with alcohol. Inferior honey usually contains a large proportion of uncrystallizable sugar and vegetable acid. Diluted with water, honey undergoes the vinous fermentation. In warm weather, honey itself, if not very pure, sometimes ferments, acquiring a pungent taste and deeper color.¹ The presence of dextrin in pure honey seems to be established. G. L. Spencer (*A. J. P.*, 1895, 27) has found as much as 4 per cent. of dextrin, and Haenle (*Zeit. An. Chem.*, 94, 99) has found that honey from *Coniferae* always contains dextrin. Künmann and Hilger (*A. J. P.*, 1896, 570) state that dextrin is present in all honey, whether dextro-rotatory or lævo-rotatory, and claim to have identified it as achroo-dextrin. Starch is said to be occasionally added to the inferior kinds to give them a white appearance. The adulteration may be detected by adding water, which dissolves the honey and leaves the starch at the bottom of the vessel. Dilution with water may be suspected from the greater thinness of the honey and its want of disposition to crystallize.

Honey is largely adulterated with artificial glucose. This may be detected by the official

tests, but the safest method is to determine the sugar by the use of Fehling's solution. The grape sugar may be determined directly in a weighed quantity of honey. An equal weight of the same honey is boiled with 2 per cent. sulphuric acid, and the sugar may be determined after inversion; finally the dextrin may be determined in a third portion by precipitation with alcohol. In pure honey the reduction after inversion with acid is not materially increased; in starch sugar (artificial glucose) it

is increased. (Allen.) According to Oscar Haenle, glucose can also be detected by first dialyzing thoroughly and then polarizing, under which circumstance, if glucose be present, rotation to the right occurs; if the honey be pure the light is not affected. Undialyzed honey ordinarily polarizes to the left, but unadulterated conifer honeys are dextrogyrate. (*P. J.*, xxi.)

Uses.—Honey possesses the same medicinal properties as sugar, but is more disposed to affect the bowels. Though largely consumed as an article of food, it is seldom employed medicinally, except as a vehicle. Its taste and demulcent qualities render it a useful addition to gargles, and it is sometimes employed as an application to *foal ulcers*.

MEL BORACIS. Br.

BORAX HONEY

(mél bō-rā'cīs)

Mel Sodii Boratis, *U. S.* 1870; Honey of Borax, Honey of Borate of Sodium; Miel boraté, Meillite de Borax, *Fr.*; Boraxhonig, *G.*

"Borax, in fine powder, 1 ounce (Imperial) or 50 grammes; Glycerin, ½ ounce (Imp.) or 25 grammes; Clarified Honey, 8 ounces (Imp.) or 400 grammes. Mix." *Br.*

This preparation was very properly dropped from the *U. S. Pharmacopœia* at the 1880 revision, as it may well be left to extemporaneous prescription. The *U. S.* formula of 1870 was practically identical with the British process given above. Borax honey is used in the thrush of infants and in aphthous ulcerations of the mouth.

¹ Müllenhoff believes that the honey is preserved in the sealed cells of the comb by the secretion with it of a minute quantity of formic acid, and has found by experiment that the addition of one part of 25 per cent. formic acid is sufficient to keep permanently 250 parts of honey, but in this connection it should be remembered that the absence of contact with the air would account for the preservation of honey in the comb.

MEL DEPURATUM. U. S., Br.

CLARIFIED HONEY [Mel Depuratum, Pharm. 1890]

(mêl dêp-û-râ'tûm)

"Honey of commerce, melted in a water-bath, and strained, while hot, through flannel previously moistened with warm water." Br.

Mellite simple, Fr. Cod.; Miel déspumé, Fr.; Mel depuratum, P. G.; Gereinigter Honig, G.; Miele depurato, It.; Miel depurada, Sp.

"Honey, a convenient quantity, Distilled Water, Glycerin, each, a sufficient quantity. Mix the Honey intimately with two percent. of its weight of paper-pulp, which has been previously reduced to shreds, thoroughly washed and soaked in water and then strongly expressed and again shredded. Then apply the heat of a water-bath, and, as long as any scum rises to the surface, carefully remove this. Finally, add enough Distilled Water to make up the loss incurred by evaporation, strain, and mix the strained liquid with five percent. of its weight of glycerin." U. S.

The U. S. method of clarifying honey was new as far as the Pharmacopœia was concerned in 1890. Paper-pulp is very effective as a clarifying agent, and the glycerin offers some protection to the honey against change. Honey may be made brilliant by hot filtration through paper. (See Remington's *Practice of Pharmacy*, "Hot Filtration," Fourth Edition, p. 214.)

Honey, by the heat of the water bath, becomes so fluid that the wax and other lighter impurities which it contains rise to the surface and may be skimmed off, while the heavier substances which may have been accidentally or fraudulently added, such as sand or other earth, sink to the bottom. It is officially required that "Clarified Honey should conform to the tests of purity given under *Mel*." U. S. A neat method of separating is described in *N. R.*, Feb. 1880. It is as follows: "Pour the honey into a perfectly clean cylindrical vessel, with straight sides, rather narrow, and having a small lip at the open margin, and heat the vessel on a water-bath. When the water is hot, pour enough honey into the vessel to fill it to within about 1 inch of the edge, and allow it to remain at rest in the water-bath, at a moderate heat, for about one hour. During this time, most of the impurities will rise to the top, while some others may sink to the bottom. Now remove the vessel very carefully from the water-bath, and pour on top of the hot honey, very gently, a sufficient amount of cold water to fill the vessel completely. This will cause all the impurities floating on the honey to rise at once to the top of the cold water, where they will often solidify to a tough skin or cake, which may be taken off without difficulty. Then pour off the water through the lip, remove the last remnants, if necessary, by means of blotting paper, and filter the honey through a piece of

well-washed, wetted, and dense white flannel. The resulting product—if the honey be pure—will be very brilliant." The French Codex simply directs four pounds of white honey to be heated with one pound of water, evaporated, skimmed, clarified by paper pulp, and then strained through flannel. Sp. gr. 1.27. The British Pharmacopœia describes it as "a viscid translucent liquid of a light-yellowish or brownish-yellow color, gradually becoming partially crystalline and opaque. It has a characteristic odor and very sweet taste. Incinerated it should not yield more than 0.25 per cent. of ash, the solution of which in water acidulated with nitric acid should not afford more than a slight turbidity with solution of barium chloride (absence of more than traces of sulphates). It should yield no characteristic reaction with the iodine test for starch." Br.

The following method of clarifying honey is recommended by André von Hirschberg. Boil 25 pounds of honey, to which half the quantity of water has been added, with a pulp obtained by stirring three sheets of white blotting paper with water, over a slow fire, till the paper is reduced to minute fibres. When the mixture cools, put it into a woollen filtering bag, previously moistened, and allow the honey to pass. It comes away quite clear. The pulp may then be washed, and the dark liquid evaporated by a water bath to the proper consistence. (*P. J.*, ix.) Another process, recommended by A. Hofmann, is to dissolve 28 pounds of honey in twice its weight of water, heat the solution to the boiling point, and then add a solution of three drachms of gelatin in three times its weight of water, and afterwards an aqueous solution of one drachm of tannin, or an infusion of two drachms of galls. The mixture is to be well stirred, and kept hot for an hour. Lastly, seven-eighths of the honey may be drawn off clear, the remainder filtered through flannel, and the whole evaporated. (*Ibid.*, xv. 121.) The use of tannin is objectionable, however, on account of its solubility in honey, and the danger of honey so purified reacting when brought in contact with ferric salts. (For other processes of purifying honey, see 14th edition of this work, p. 1321, and *A. J. P.*, 1877, p. 19; also 1879, pp. 193, 598; and 1880, p. 132.) Heugel's method is to mix two pounds each of honey and water with a half-ounce of magnesium carbonate, frequently agitate for two or three hours, filter through doubled white filtering paper, boil slowly, remove the scum carefully, and evaporate upon a steam bath to a syrupy consistence. Dieterich recommends the following process: Mix the honey with sufficient water (the amount depending on the consistence), heat for about seven hours on a water bath, and clarify it with 5 per cent. of its weight of powdered talc, neutralize, if necessary, with magnesium carbonate; allow to deposit, filter, add a few drops of acetic acid, and evaporate to the proper specific gravity. (*Ph. Ztg.*, 93, 712.)

Honey clarified with calcium carbonate and animal charcoal, or as in the first process described, is as clear and colorless as syrup made with sugar, but still retains a peculiar flavor. It is less disposed to ferment than crude honey, and is said not to be so liable to produce griping pain when swallowed.

Dose, one to four fluidrachms (3.75 to 15 Ce.).

Off. Prep.—*Confectio Piperis*, Br.; *Confectio Rosæ*, U. S.; *Hydrargyrum cum Creta*, U. S.; *Massa Ferri Carbonatis*, U. S.; *Mel Boracis*, Br.; *Mel Rosæ*, U. S.; *Oxymel*, Br.; *Oxymel Scillæ*, Br.

MEL ROSÆ. U. S.

HONEY OF ROSE

(mēl rō'sæ)

Mellitum Rosatum; *Mellite de Rose rouge*, Fr. *Cod.*; *Miel Rosat*, Fr.; *Mel Rosatum*, P. G.; *Rosenhonig*, G.; *Miele rosato*, It.; *Miel de rosas*, Sp.

* "Fluidextract of Rose, one hundred and twenty cubic centimeters [or 4 fluidounces, 28 minims]; Clarified Honey, a sufficient quantity, to make one thousand grammes [or 35 ounces av., 120 grains]. Into a tared vessel introduce the Fluidextract of Rose, then add enough Clarified Honey to make the contents weigh one thousand grammes [or 35 ounces av., 120 grains], and mix thoroughly." U. S.

Though one of the official preparations in the London and Edinburgh Pharmacopœias, the Honey of Rose has been dropped in the British. The U. S. formula is based on that of Grahame. (See *A. J. P.*, 1859, p. 443.) As is well known, honey of rose deposits honey sugar upon standing even but a short time. Touffet (*Ph. Centralh.*, xxxvi. 307) obviates this precipitation in the following manner: Take of Powdered Rose Leaves, 25 parts; Alcohol, sp. gr. 0.875, 75 parts; Honey, 80 parts; Sugar, 34 parts. Percolate the rose leaves with the alcohol, filter and distil off the filtrate to 40 parts. To this add the honey and sugar, and bring to the boiling point. Honey of rose forms a pleasant addition to the gargles employed in inflammation and ulceration of the mouth and throat.

Dose, one fluidrachm (3.75 Ce.).

MENTHA PIPERITA. U. S.

PEPPERMINT

(mēn'thā pīp-ē-rī'tā)

"The dried leaves and flowering tops of *Mentha piperita* Linné (Fam. *Labiata*)." U. S.

Brandy Mint, Lamb Mint; *Menthe poivrée*, Fr. *Cod.*; *Folia Menthe Piperitæ*, P. G.; *Pfefferminzblätter*, Pfeffermünze, G.; *Menta piperita*, It., Sp.

The genus *Mentha* comprises at least fifteen species, of which there are also a great many varieties. *M. piperita*, L. (1753), also Smith (1800),—the most important member of this genus, was long ago cultivated by the Egyptians,

and is now grown in considerable amounts in Europe, North America, and Eastern Asia. It is also found growing wild in other parts of the world, as South America and Australia. The oldest existing peppermint district is in the neighborhood of Mitcham (Surrey), England. In some parts of the United States, especially in Michigan, the western part of New York, Ohio and Indiana, it is largely cultivated.¹ On the continent of Europe other species of *Mentha* (particularly *M. arvensis*) grow with *M. piperita*, deteriorating the product. In America other plants (as *Erigeron canadensis* and *Erechtites hieracifolia*) cause the same trouble. Besides *M. piperita* other species are cultivated, as some Asiatic varieties of *M. arvensis*, *M. spicata*, *M. longifolia* (var. *undulata*), *M. gentilis*, *M. dalmatica*, and *M. Pulegium*. For an account of the cultivation of peppermint in Russia see *Proc. A. Ph. A.*, 1902, 831.

Mentha piperita, L., *Sp. Pl.* (1753) 576; Willd., *Sp. Plant.* iii. 79; B. & T. 203; Carson, *Illustr. of Med. Bot.*, ii. 16, pl. 63.—Peppermint is a perennial herbaceous plant, with a creeping root, and quadrangular, channelled, purplish, somewhat hairy stems, branched towards the top, and about two feet in height. The leaves are about two inches long, opposite, petiolate, ovate, serrate, pointed, smoother on the upper than on the under surface, and of a dark green color, which is paler beneath. The flowers are small, purple, and in terminal obtuse spikes, interrupted below, and cymosely arranged. Late in the season, the growth of the lateral lower branches often gives to the inflorescence the appearance of a corymb. The calyx is tubular, furrowed, and five-toothed, often purplish; the corolla is purplish, tubular, with its border divided into four segments, of which the uppermost is broadest, and notched at its apex. The four short stamens are concealed within the tube of the corolla; the style projects beyond it, and terminates in a bifid stigma. The plant should be cut for medicinal use in dry weather, in August, about the period of the expansion of the flowers. John C. Umney points out differences between white and black peppermint in *P. J.*, 1896, 123. For a paper on the histology of powdered peppermint by Smith Ely Jelliffe see *D. C.*, 1899, 252.

Properties.—It is officially described as follows: "Branches quadrangular, with scattered, deflexed hairs; leaves petiolate, ovate-lanceolate, 3 to 8 Cm. long, acute, sharply serrate, light or dark green; flower-whorls in oblong or oval spikes which are usually compact, or somewhat interrupted at the base, 1 to 1.5 Cm. broad, rounded at the summit, when in fruit becoming 3 to 7 Cm. long; calyx tubular, 5-toothed and often purplish; corolla small, purplish, and 4-lobed; stamens four, short and

¹ For an interesting account of the distribution of the peppermint culture in the United States and the amount of oil produced in 1897, see *Schimmel & Co.'s Report* for October, 1897, 40.

equal; odor strong and characteristic; taste pungent and cooling." *U. S.* The herb, both in the recent and in the dried state, has a peculiar, penetrating, grateful odor. There is sometimes difficulty in distinguishing between the leaves of *M. piperita* and those of *M. spicata*. According to Joseph Schrenk, crystals can always be found in the glandular hairs of the peppermint, but are absent in those of the spearmint. The crystals are doubly refractive, and so transparent that sometimes a polariscope is necessary for their easy detection. These crystals have been thought to be menthol, but they seem not to dissolve in alcohol, and their nature remains doubtful. The taste of the herb is aromatic, warm, pungent, camphorous, bitterish, and attended with a sensation of coolness when air is admitted into the mouth. These properties depend on a volatile oil, of which from 1 to 1.25 per cent. can be obtained from the herb. The leaves are said to contain a little tannic acid. The virtues of the herb are imparted to water, and more readily to alcohol.

Uses.—Peppermint is an aromatic stimulant, much used to allay nausea, relieve spasmodic pains of the stomach and bowels, expel flatus, or cover the taste or qualify the nauseating or griping effects of other medicines. The medicine is rarely used in infusion. (See *Oleum Menthae Piperitæ*.)

Dose, one drachm (3.9 Gm.).

MENTHA VIRIDIS. U. S.

SPEARMINT

(mĕn'thā vīr'ī-dīs)

"The dried leaves and flowering tops of *Mentha spicata* Linné (*Mentha viridis* Linné) (Fam. Labiatae)." *U. S.*

Herba Menthae Acutæ (vel Romanæ); Brown, Lamb. Garden, or Mackerel Mint; Menthe verte, *Fr. Cod.*; Menthe romaine, Baume vert, Menthe à épi, *Fr.*; Grüne Münze, Römische Münze, *G.*

Mentha spicata, L., *Sp. Pl.* (1753) 576.—*Mentha viridis*, L., *Sp. Pl.* (1763) 804; Willd., *Sp. Plant.* iii. 76; B. & T. 302. *M. spicata*, var. *viridis*, L. (1753).

Spearmint, sometimes called simply *mint*, differs from *M. piperita* chiefly in having sessile or nearly sessile, lanceolate, naked leaves; elongated, interrupted, panicle spikes; setaceous bracts; and stamens longer than the tube of the corolla. It is a native of Europe and Asia, and naturalized in waste places from Nova Scotia and Ontario to Minnesota and Kansas in the West and Florida in the South United States. It is also cultivated for domestic use and for the sake of its oil. Its flowering season is August. The dried herb is officially described as "closely resembling Peppermint (see *Mentha Piperita*), but the leaves usually sessile and lanceolate, the flower-spikes usually slender, interrupted, cylindrical, or

crowded, conical at the apex, 5 to 8 Mm. thick, becoming when in fruit 5 to 10 Cm. long; the stamens rather long; odor and taste resembling, but distinguishable from those of Peppermint." *U. S.* The taste and odor are retained for some time by the dried plant. They depend on a volatile oil. (See *Oleum Menthae Viridis*.) Medicinally this oil acts like the oil of peppermint.

Dose, one drachm (3.9 Gm.).

MENTHOL. U. S., Br.

MENTHOL

(mĕn'thōl)

$C_{10}H_{18}OH = 154.98$

"A secondary alcohol [$C_6H_5(CH_3)(OH)(C_8H_7)1:3:4$], obtained from the oil from *Mentha piperita* Linné, or other peppermint oils. Menthol should be kept in well-stoppered bottles, in a cool place." *U. S.* "A crystalline substance, $C_6H_5.OH.CH_3.C_8H_7$, obtained by cooling the oil distilled from the fresh herb of *Mentha arvensis*, *DC.*, vars. *piperascens* et *glabrata*, *Holmes*; and of *Mentha piperita*, *Sm.*" *Br.*

Pipmenthol, Peppermint Camphor; Menthol, *Fr. Cod.*; Camphre de Menthe, *Mentholum, Fr.*; Mentholum, *P. G.*; Menthol, Pfefferminzcampher, *Mentha-Kampher*, Pip-menthol, *G.*; Mentolo, *It.*; Mentol, *Sp.*

Menthol was admitted to the Br. Pharmacopœia of 1885, and was one of the new official substances of the U. S. Pharmacopœia 1890. Menthol, or *peppermint camphor*, may be obtained from either American or Japanese oil of peppermint by cooling the oil to a very low temperature, when the menthol crystallizes out, often in a dense mass; the adhering oil may be separated by expression. Menthol may also be obtained by fractional distillation, and there is reason to believe that the oil of peppermint of commerce is often contaminated with the dementholized oil. A larger yield of menthol is obtained from Japanese or Chinese oils, and for this reason Japanese menthol is largely found in commerce. It is practically identical with American menthol, differing, however, in the character of its crystals, which occur in small prisms instead of in long needles.

Properties.—The U. S. P. describes it as in "colorless, acicular or prismatic crystals having a strong and pure odor of peppermint, and a warm, aromatic taste, followed by a sensation of cold when air is drawn into the mouth. Menthol is only slightly soluble in water, but imparts to the latter its odor and taste. It is freely soluble in alcohol, ether, and chloroform. It melts at 43° C. (109.4° F.) to a colorless liquid, boils at 212° C. (413.6° F.), and volatilizes slowly at the ordinary temperature. When it is triturated with about an equal weight of camphor, thymol, or hydrated chloral, the mixture becomes liquid. Its alcoholic solution is neutral to litmus paper, and is lavogyrate. If a little Menthol be

heated in an open dish, on a water-bath, it should gradually volatilize without leaving any residue (absence of *wax, paraffin, or inorganic substances*). If a few crystals of Menthol be dissolved in 1 Cc. of glacial acetic acid, and then 3 drops of sulphuric acid and 1 drop of nitric acid added, no green color should be produced (absence of *thymol*).” *U. S.* “Melting point 107.6° F. (42° C.); it should not exceed 109.4° F. (43° C.). It has the odor and flavor of peppermint, producing a sensation of warmth on the tongue, and, if air is inhaled, a sensation of coolness. It is very slightly soluble in *water*, but readily soluble in *alcohol* (90 per cent.), the solutions having a neutral reaction. Boiled with *sulphuric acid* diluted with half its volume of *water*, Menthol acquires an indigo-blue or ultramarine color, the acid becoming brown. It should be entirely volatilized by the heat of a water-bath.” *Br.*

Menthol belongs to the class of camphors. Its formula may be written $C_{10}H_{18}OH$, as it is recognized as being a saturated secondary alcohol. Chromium trioxide oxidizes menthol to *dextro- and levo-menthone*, $C_{10}H_{18}O$, which is the ketone corresponding. The *menthones* are liquids, with an odor resembling that of peppermint. They boil at 207° C. Distillation with zinc chloride or phosphoric anhydride changes menthol into liquid *menthene*, $C_{10}H_{18}$, boiling at 167° C. (See papers by Kremers, Urban, and Richtmann on the menthol group, *Proc. A. Ph. A.*, 1893, 185; also 1896, 200.) Menthol has been grossly adulterated with spermaceti, paraffin, etc., and, after being compressed into pencils or cones, sold as a local panacea for headache and neuralgia.

Uses.—According to Pellacani, menthol is a spinal and motor nerve trunk paralyzant destroying both motility and sensibility. It also acts upon the sensory nerves. It is germicidal and resembles phenol in its general medicinal action. It is sometimes administered as an intestinal antiseptic but is chiefly used externally, especially as a local anæsthetic application for the relief of *neuralgic pains, toothache, sciatica*, etc. When it is applied in solid form to the skin it produces a burning pain, associated with a sensation of cold and some benumbing of the skin, and it is chiefly used in the shape of cones without dilution. In this way it has had a very wide popularity in the treatment of *headache, neuralgia*, and *superficial pains* of various character, but is at present not so much used as formerly. According to S. A. Russel, an ethereal solution of the strength of from 10 to 50 per cent. applied two or three times a day has a remarkable power of controlling superficial inflammations, such as *boils, carbuncles*, etc. Its solution (from two to ten grains in a fluidounce of water) is said to be effective in *pruritus ani, chronic painful eczemas, urticaria*, etc. It is also largely used as a local remedy in the treatment of inflammations about the mouth, such

as *stomatitis, angina, tonsillitis*, etc., dissolved in liquid petrolatum, two grains to the fluidounce, or in troches.

Dose, one to two grains (0.065 to 0.13 Gm.).

METHYLIS SALICYLAS. U. S.

METHYL SALICYLATE

[Methyl Salicylas, Pharm. 1890, Synthetic Oil of Gaultheria, Synthetic Oil of Wintergreen]

(mēth'yl-is sāl-i-cyl'las)

$CH_3C_7H_5O_3 = 150.92$

“An ester [$C_6H_4(OH)COOCH_3$] 1 : 2], produced synthetically; it is the principal constituent of Oil of Gaultheria and Oil of Betula. For flavoring purposes, Oil of Gaultheria, Oil of Betula, and Methyl Salicylate may be regarded as identical products. It should be kept in well-stoppered bottles, protected from light.” *U. S.*

Salicylate de Méthyle, *Fr.*; Methylsalicylat, *Künstliches Wintergrünöl, G.*

Methyl salicylate, or *artificial oil of wintergreen*, was introduced into the U. S. P. 1890 largely because of its extensive use and on account of its being a valuable synthetic; it is asserted that it can be produced of more uniform quality and is more definite and certain in its action than either the oil from gaultheria or the oil from birch, which are natural oils. (See *A. J. P.*, 1889, p. 398; *Ph. Rund.*, 1889, 283; see also 1892, p. 7, 9.) Methyl salicylate may be made by distilling salicylic acid, or a salicylate, with methyl alcohol and strong sulphuric acid. The following process was devised by G. M. Beringer (*A. J. P.*, 1887, p. 8). Dissolve half an ounce of salicylic acid in two fluidounces of absolute methyl alcohol, then gradually add one fluidounce of sulphuric acid; warm gently for twenty-four hours, then distil from a retort into which a current of steam is introduced. The distillate is to be well washed, and separated by decantation. The odor improves with age. Methyl salicylate has been found in a great number of plants. (See *A. J. P.*, 1898, 412; *Ph. Rev.*, 1898, 130; *Schim. Rep.*, 1898, 45; 1899, 46.)

Properties.—Methyl salicylate is officially described as “a colorless liquid, having a characteristic, strongly aromatic, wintergreen odor, and a sweetish, warm, and aromatic taste. Specific gravity: 1.180 to 1.185 at 25° C. (77° F.), according to the amount of moisture present. Boiling point: 219° to 221° C. (426.2° to 429.8° F.). It is optically inactive. Sparingly soluble in water; soluble, in all proportions, in alcohol, glacial acetic acid, and carbon disulphide. The alcoholic solution is neutral or slightly acid to litmus paper. If a drop of Methyl Salicylate be shaken with a little water, and a drop of ferric chloride

T.S. subsequently added, a deep violet color will be produced. When heated on a water-bath, in a flask provided with a suitable condenser, it should yield no distillate having the characteristics of *alcohol* or *chloroform*. If to 1 Cc. of Methyl Salicylate, contained in a capacious test-tube, 10 Cc. of sodium hydroxide T.S. be added, and the mixture agitated, a bulky, white, crystalline precipitate will be produced; then, if the test-tube, loosely corked, be allowed to stand in boiling water for about five minutes, with occasional agitation, the precipitate should dissolve, and form a clear, colorless or faintly yellowish solution, without the separation of any oily drops, either on the surface or at the bottom of the liquid (absence of *volatile oils*, or of *petroleum*). If the alkaline liquid thus obtained be subsequently diluted with about three times its volume of water, and a slight excess of hydrochloric acid added, a white, crystalline precipitate will be produced which, when collected on a filter, washed with a little water, and recrystallized from hot water, should respond to the tests of identity and purity given under *Acidum Salicylicum* (absence of *methyl benzoate*, etc.)." U. S.

Uses.—So far as is known, the physiological and remedial properties of the artificial oil of gaultheria do not differ from those of the natural product. (See *Oleum Gaultheriæ*.)

Dose, fifteen to thirty minims (0.9 to 1.8 Cc.).

Off. Prep.—Cataplasma Kaolini, U. S.

METHYLTHIONINÆ HYDRO- CHLORIDUM. U. S.

METHYLTHIONINE HYDROCHLORIDE METHYLENE BLUE

(mêth-yl-thi-ô-nî-næ hÿ-drô-ghlô'rî-dûm)

$C_{16}H_{18}N_3SCl = 317.36$

"Tetramethylthionine Hydrochloride, obtained by the action of hydrogen sulphide upon an oxidation product of para-amido-dimethyl-aniline." U. S.

Chlorhydrate de Tetraméthylthionine, *Fr.*; Tetramethylthioninchlorid, *Methylen. Blau*, *G.*

This synthetic dye color belongs to the class of *thiazines* or dyestuffs in which two benzene nuclei are united by a nitrogen atom and a sulphur atom. Methylene blue was discovered by Caro in 1876, and was made by the oxidation of *p*-amido-dimethyl aniline in the presence of hydrogen sulphide. Both the hydrochloride of the base and the zinc chloride double salt of the same are known by the name of methylene blue. It is only the former that is used in medicine and constitutes the official salt. Methylene Blue must not be confounded with *methyl blue*, a dark blue powder which is used as an antiseptic; the latter is sodium triphenyl-pararosaniline-sulphonate.

Properties.—Methylene blue is officially described as "a dark green, crystalline powder, or in the form of prismatic crystals having a bronze-like lustre. It is readily soluble in water and somewhat less readily in alcohol, the solutions having a deep blue color. The addition of hydrochloric acid to its aqueous solution changes the color to a lighter shade of blue. The addition of sodium hydroxide T.S. to the aqueous solution changes the color to a purplish shade, and if added in excess, produces a precipitate having a dull violet color. The dry powder dissolved in sulphuric acid containing powdered zinc produces a solution which, upon standing, is gradually decolorized. Two Gm. of Methylthionine Hydrochloride, when ignited, should leave not more than 0.008 Gm. of residue, which should be free from zinc oxide (absence of *commercial dye*, and *other mineral impurities*). Two Gm. of Methylthionine Hydrochloride ignited with dry sodium carbonate and potassium nitrate should leave a residue which should not respond to the Modified Gutzeit's Test for *arsenic* (see PART III, Test No. 17)." U. S.

Uses.—When taken internally methylene blue is absorbed and eliminated chiefly from the kidneys, coloring the urine blue. In therapeutic doses it produces no symptoms, and we know of no recorded cases of poisoning with the pure article. It is a feeble antiseptic and has been used to a considerable extent in *gonorrhœa*, *cystitis* and *pyelitis*, but its value is certainly not great. As an analgesic, it has been employed to a considerable extent in *neuralgia*, *locomotor ataxia*, etc., but is inferior to other aniline derivatives. In 1891, Ehrlich and Guttman (*B. K. W.*, xxviii), led by its power as a staining agent over the malarial plasmodium, suggested its practical use as an antiperiodic, and its value as such is well established. In 425 cases collected by H. C. Wood, Jr., there were 85 per cent. of recoveries. It does not produce disturbances of the special senses or of the gastro-intestinal tract, and therefore may be preferable to quinine in aural or gastro-intestinal affections. Further, on account of its lack of action upon the kidney, it is especially valuable in those forms of *malaria* accompanied with *hematuria*, the so-called "*black water fever*." If the statement of Iwanoff, that it especially acts upon the adult forms of plasmodium be correct, it should be especially valuable in *chronic malaria*, and experience may prove that the best treatment of this condition is the administration of full doses of quinine at intervals of seven days, with the continuous use of the methylene blue.

Methylene blue is preferably administered in capsule. In malaria from ten to twenty grains (0.65 to 1.3 Gm.) may be given in the course of a day for ten days, and after this six to ten grains (0.4 to 0.65 Gm.) a day for two weeks. In obstinate cases a full dose of quinine may be exhibited every seventh day, the methylene

blue being omitted. The staining action of methylene blue upon any portion of the body or clothing with which it may come in contact, and its color effect upon the urine, should always be explained to the patient.

Dose, two to five grains (0.13 to 0.32 Gm.).

MEZEREUM. U. S. (Br.)

MEZEREUM

(mē-zě'rē-ūm)

"The dried bark of *Daphne Mezereum* Linné, and of other European species of *Daphne* (Fam. *Thymeleaceæ*)."
U. S. "The dried bark of *Daphne Mezereum*, Linn., or of *Daphne Laureola*, Linn., or of *Daphne Gnidium*, Linn."
Br.

Mezerel Cortex, Br., *Mezereon Bark*; *Cortex Mezerei*, *Cortex Thymeleæ* (vel *Coccognidii*); *Dwarf Bay*, *Wild Pepper*, *Spurge-flax*, *Spurge-olive*, *Magell*; *Mezereon* ou *Bols gentil*, Fr. Cod.; *Lauréole*, *Thymele*, Fr.; *Kellerhals*, *Seidelbastrinde*, *Kellerhalsrinde*, G.; *Mezereo*, It.; *Mezereon*, Sp.

All the species of *Daphne* are possessed of active properties, but three only are official,—*D. Mezereum*, *D. Laureola*, and *D. Gnidium*, all of which are recognized in the British Pharm., and only the last in the French Codex.

1. *Daphne Mezereum*, L., *Sp. Pl.* (1753) 356; Willd., *Sp. Plant.* ii. 415; B. & T. 225; Carson, *Illustr. of Med. Bot.*, ii. 26, pl. 72.—This is a very hardy shrub, three or four feet high, with a branching stem, and a smooth, dark gray bark, very easily separable from the wood. The leaves spring from the ends of the branches, are deciduous, sessile, obovate-lanceolate, entire, smooth, of a pale green color, somewhat glaucous beneath, and about two inches long. They are preceded by the flowers, which appear very early in spring, and sometimes bloom even amidst the snow. These are of a pale rose color, highly fragrant, and disposed in clusters, each consisting of two or three flowers, forming together a kind of spike at the upper part of the stem and branches. At the base of each cluster are deciduous floral leaves. The fruit is oval, shining, fleshy, of a bright red color, and contains a single round seed. Another variety produces white flowers and yellow fruit. This species of *Daphne* occurs throughout the forests of Europe, and extends in Western Asia from the Caucasus to the Altai. It is cultivated in Europe, and is occasionally found in our own gardens.

2. *Daphne Gnidium*, Willd., *Sp. Plant.* ii. 420; B. & T. 227.—In this species, called *garou* or *sain-bois* by the French, the leaves are linear-lanceolate, acute, entire, smooth, and irregularly but closely set upon the branches. The flowers are white, downy, odoriferous, and disposed in terminal panicle racemes. The fruit is globular, dry, at first green, but ultimately black. *D. Gnidium* grows in dry uncultivated places in the south of Europe, and flowers in June. Its bark, which in France is used indiscriminately with that of the

former species, is of a deep purplish-brown color, and hairy in the younger portions. It appears to be equally as active, medicinally, as the other official species.

Besides the species above described, *Daphne Laureola*, or *spurge laurel*, is said to furnish a portion of mezereum of commerce, and is recognized by the British Pharmacopœia, but its product is inferior in acrimony, and consequently in medicinal activity.

Properties.—Mezereum, as it comes to us, chiefly from Germany, is in strips from two to four feet long and an inch or less in breadth, sometimes flat, sometimes partially rolled, and always folded in bundles or wrapped in the shape of balls. It is covered externally with a grayish or olive-, purplish-, or reddish-brown wrinkled epidermis, with transverse scars and minute black dots, very thin, and easily separable from the bark. Beneath the epidermis is a soft, greenish tissue. The inner bark is tough, pliable, fibrous, striated, and of a whitish color, with a silky surface. Its transverse section exhibits numerous groups of bast fibres in the secondary bast. When fresh it has a nauseous odor, but in the dry state is nearly inodorous. Its taste is first sweetish, but afterwards acid and even corrosive. It yields its virtues to water by decoction.

The bark of the root was formerly directed, but the mezereum with which our markets are supplied is evidently the bark of the stem, and the Pharmacopœias at present very properly direct the bark, without designating the part from which it must be taken. The official description is as follows: "In long, thin, flexible, tough bands, the edges fringed with partly detached bast fibres; outer surface yellowish- or reddish-brown, obliquely striate or wrinkled, with numerous lenticels and occasional brownish-black fruit-heads of a lichen; inner surface yellowish-green or whitish, satiny-lustrous, finely striate; fracture tough, fibrous, the periderm readily separable from the yellowish-green cortex, inner bark lamellated; odor slight; taste very acid." U. S. British writers state that the bark of the root is the most active. The berries and leaves of the plant are also active, and the former have sometimes proved fatal to children who have eaten them. Pallas states that they are used as a purgative by the Russian peasants, and that thirty berries are required to act. French authors observe that fifteen are sufficient to kill. A tincture of them is used in Germany as a local application in *neuralgia*.

Vauquelin discovered a peculiar principle in the bark of *Daphne alpina*. This has subsequently been found in other species, and has received the name of *daphnin*. Gmelin and Bär found it in the bark of *D. Mezereum*, associated with wax, an acid resin, a yellow coloring matter, a reddish-brown extractive, and uncrystallizable and fermentable sugar, a gummy matter containing nitrogen, ligneous fibre, malic acid, and several malates. By J.

B. Eng it has been discovered, together with a volatile oil, in the flowers of *D. Mezereum*. (Wittstein's *Viertelj.*, viii. 23.) Daphnin is in prismatic crystals, grouped together, colorless, transparent, brilliant, slightly soluble in cold water, very soluble in boiling water and alcohol, without odor, and of a bitter, somewhat austere taste. By Zwenger it is said to be insoluble in ether. The same chemist states that it has an acid reaction, and acts like the glucosides, being resolvable by sulphuric or hydrochloric acid into sugar, and a peculiar crystallizable principle called *daphnetin*, $C_6H_5O_4 + H_2O$. He gives for daphnin the formula $C_{15}H_{15}O_8 + 2H_2O$, the same as that of *æsculin*, of which it is, therefore, an isomer. (*Ann. Ch. Ph.*, cxv. 1.)

The glucoside daphnin may be obtained by treating the alcoholic extract of the bark with water, decanting the solution, precipitating with lead subacetate, filtering, decomposing the excess of the subacetate by hydrogen sulphide, again filtering, evaporating to dryness, submitting the residue to the action of anhydrous alcohol, and evaporating the alcoholic solution to the point of crystallization. Though daphnin is probably not inert, it is not the principle upon which the virtues of mezereum chiefly depend. Vauquelin thinks that in the recent plant they reside in an essential oil, which by time and exposure is changed into a resin, without losing its activity. The acrid resin observed by Gmelin and Bär is probably the characteristic principle to which the bark owes its vesicating properties. It is obtained separate by boiling mezereum in alcohol, allowing the liquor to cool in order that it may deposit some wax which it has taken up, then distilling off the alcohol, and treating the residue with water, which leaves the resin. This is of a dark green, almost black color, hard and brittle, and of an exceedingly acrid and permanent taste. In the isolated state it is slightly soluble in water, and it is much more so when combined with the other principles of the bark. It appears, however, not to be a pure proximate principle, but rather a resinoid combination of an acrid fixed oil with another substance. The acrid principle of mezereum is partially given off by decoction with water, as proved by the irritating character of the vapor; but none of it appears to escape when the bark is boiled with alcohol. (Squire, *P. J.*, i.) W. Will and O. Jung have investigated daphnetin, which was shown in 1879 by Stünkel to be *dioxy coumarin*,

about one ounce of daphnetin from fifty pounds of extract of mezereum, and they proved that it has the same relation to pyrogallie acid that coumarin has to phenol, or umbelliferone to resorcinol. (*A. J. P.*, 1885.) *Coccognin*, isolated in 1870 by Casselmann from the fruits of *D. Mezereum*, appears to be closely allied to,

if not identical with, daphnin. By the dry distillation of an alcoholic extract of mezereum bark, Zwenger obtained *umbelliferone*, $C_8H_6O_3$.

Uses.—The recent bark applied to the skin produces inflammation followed by vesication, and has been popularly used as an epispastic, from time immemorial, in some of the southern countries of Europe. The dried bark, though less active, is possessed of a similar property, and is occasionally employed in France by regular practitioners for the purpose of forming issues. A small square piece, moistened with vinegar, is applied to the skin, and renewed twice a day until a blister is formed, and occasionally afterwards to keep up the discharge. It is slow in its operation, generally requiring from twenty-four to forty-eight hours to vesicate. An irritant ointment¹ is prepared from mezereum, which is used for maintaining the discharge from blistered surfaces, and may be applied advantageously to obstinate, ill-conditioned, indolent *ulcers*. An alcoholic extract has also been employed to communicate irritant properties to issue-peas. Internally administered, mezereum is a stimulant capable of being directed to the skin or kidneys, and in large doses likely to excite purging, nausea, and vomiting. In overdoses it produces the fatal effects of the acrid poisons, and a case of apparently severe narcotic effects has been recorded. (*Am. J. M. S.*, xxi.) It had at one time much reputation as a remedy in the *secondary stages of syphilis*, and still enters as an ingredient into the compound decoction of sarsaparilla. It has also been thought to act favorably as an alterative in *scrofulous affections, chronic rheumatism, and obstinate diseases of the skin*. For this purpose it is usually given in decoction, never in substance.

Dose, ten grains (0.65 Gm.).

Off. Prep.—Fluidextractum Mezerei, *U. S.*;
Fluidextractum Sarsaparillæ Compositum, *U. S.*;
Liquor Sarsæ Compositus Concentratus, *Br.*

MISTURA AMMONIACI. Br.

'AMMONIACUM MIXTURE

(mjs-tū'ā ām-mō-nī'ā-āi)

Emulsion Ammoniaci, *U. S.* 1890. Emulsion of Ammoniac; Ammoniac Mixture; Emulsion Ammoniac, *Lac Ammoniac*; Milk of Ammoniac; Mixture de Gomme ammoniacque, Lait d'ammoniaque, *Fr.*; Ammoniak-Emulsion, *G.*

¹ *Unguentum Mezerei*, *U. S.* 1880. *Mezereum Ointment*; *Pommade épispastique au Garou*, *Pommade de Mezereum*, *Fr.*; *Scidelbastsaibe*, *G.*—"Fluid Extract of Mezereum, twenty-five parts [or two fluidrachms]; Lard, eighty parts [or three hundred and sixty grains]; Yellow Wax, twelve parts [or fifty-four grains] [to make about one ounce av.]. Melt together the Lard and Wax with a moderate heat, add the Fluid Extract, and stir the mixture constantly until the alcohol has evaporated; then continue to stir until cool." *U. S.* 1880.

This ointment is equivalent to the *Pommade épispastique au Garou* of the French Codex, which is prepared from the bark of *Daphne Genkwa*. It may also be made, as proposed by Guibourt, by mixing two drachms of the alcoholic extract of mezereum with nine ounces of lard and one ounce of wax. It is used as a stimulating application to blistered surfaces and to obstinate, ill-conditioned, and indolent *ulcers*.

"Ammoniacum, in coarse powder, $\frac{1}{2}$ ounce (Imperial) or 5 grammes; Syrup of Tolu, 4 fl. drachms (Imp. meas.) or 10 cubic centimetres; Distilled Water, $7\frac{1}{2}$ fl. ounces (Imp. meas.) or 150 cubic centimetres. Triturate the Ammoniacum thoroughly with a little of the Distilled Water so as to form a thin paste; gradually add the remainder of the Distilled Water and the Syrup of Tolu, triturating until the mixture assumes a uniform milky appearance; strain through muslin." *Br.*

In this emulsion the resinous and oily constituents are suspended by means of the gum of the ammoniac, imparting a milky appearance to the preparation, which from this circumstance was formerly called *lac ammoniaci*, or *milk of ammoniac*. The greater portion of the resin subsides upon standing. This emulsion is no longer official in the U. S. P. (8th Rev.), the process of the U. S. P. 1890 is appended.¹ The British Pharmacopœia (1898) process directs the addition of a small quantity of syrup of Tolu, doubtless as a flavoring agent. The mixture is slightly curdled by acids.

Dose, one-half to a fluidounce (15 to 30 Cc.).

MISTURA CREOSOTI. *Br.*

CREOSOTE MIXTURE

(mĭs-tŭ'ra crē-q-sō'tī)

Mixture de Créosote, *Fr.*; Kreosotmĭxtur, *G.*

"Creosote, 16 minims (Imperial measure) or 1 cubic centimetre; Spirit of Juniper, 16 minims (Imp. meas.) or 1 cubic centimetre; Syrup, 1 fl. ounce (Imp. meas.) or 30 cubic centimetres; Distilled Water, a sufficient quantity. Shake the Creosote with fourteen fluid ounces (Imp. meas.) or four hundred and twenty cubic centimetres of the Distilled Water; add the Syrup and the Spirit of Juniper, and sufficient Distilled Water to produce sixteen fluid ounces (Imp. meas.) or four hundred and eighty cubic centimetres of the Mixture." *Br.* The glacial acetic acid has been omitted from creosote mixture by the *Br. Ph.* 1898.

Dose, of this mixture, which is too weak for practical use, a fluidounce (30 Cc.), containing a minim (0.06 Cc.) of creosote.

MISTURA CRETÆ. U. S., *Br.*

CHALK MIXTURE

(mĭs-tŭ'ra crē'tæ)

Mixture avec la Craie, *Fr.*; Kreidemĭxtur, *G.*

* "Compound Chalk Powder, twenty grammes [or 309 grains]; Cinnamon Water, forty

cubic centimeters [or 1 fluidounce, 169 minims]; Water, a sufficient quantity, to make one hundred cubic centimeters [or 3 fluidounces, 183 minims]. Rub the Compound Chalk Powder in a mortar, with the Cinnamon Water and about twenty cubic centimeters [or 325 minims] of Water gradually added, to a uniform mixture; transfer this to a graduated vessel, and rinse the mortar with enough Water to make the product measure one hundred cubic centimeters [or 3 fluidounces, 183 minims]. Mix the whole thoroughly. This preparation should be freshly made when wanted." *U. S.*

"Prepared Chalk, $\frac{1}{2}$ ounce (Imperial) or 5 grammes; Tragacanth, in powder, 15 grains (Imp.) or 0.7 gramme; Refined Sugar, $\frac{1}{2}$ ounce (Imp.) or 10 grammes; Cinnamon Water, a sufficient quantity. Triturate the Prepared Chalk with the Tragacanth and Refined Sugar, and gradually add sufficient Cinnamon Water to produce eight fluid ounces (Imp. meas.) or one hundred and sixty cubic centimetres of the Mixture." *Br.*

The direction that this mixture be prepared extemporaneously is a decided improvement. Unsuccessful attempts have been repeatedly made to devise a formula which would yield a permanent product, and much injury has been done through the dispensing of chalk mixture in an incipient fermentative condition. The trifling amount of glycerin present in the chalk mixture official in 1870 was totally inadequate to preserve it during the warm summer months, when it is in greatest vogue. Compound Chalk Powder is now official (see *Pulvis Cretæ Compositus*); it will keep indefinitely, and, besides being itself a valuable addition to the materia medica, is quickly made into chalk mixture by rubbing it with the water and cinnamon water, so that there can be no excuse for not dispensing a fresh mixture. This mixture is a convenient form for administering chalk, and is much employed in looseness of the bowels accompanied with acidity. Laudanum and kino or catechu are very often added to increase its astringency.

Dose, four fluidrachms (15 Cc.), frequently repeated.

MISTURA FERRI COMPOSITA.

U. S., *Br.*

COMPOUND IRON MIXTURE [Griffith's Mixture]

(mĭs-tŭ'ra fēr'ri cōm-pōs'ī-tā)

Mixture ferrugineuse de Griffith, *Fr.*; Griffithsche Eisenmĭxtur, *G.*

* "Ferrous Sulphate, in clear crystals, six grammes [or 93 grains]; Myrrh, in small pieces, eighteen grammes [or 278 grains]; Sugar, eighteen grammes [or 278 grains]; Potassium Carbonate, eight grammes [or 123 grains]; Spirit of Lavender, sixty cubic centimeters [or 2 fluidounces, 14 minims]; Rose Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6 $\frac{1}{2}$ fluidrachms].

¹ *Emulsion Ammoniaci*, U. S. 1890. *Emulsion of Ammoniac* [*Mistura Ammoniaci*, *Pharm.* 1880.]. "Ammoniac, forty grammes [or 1 ounce av., 180 grains]; Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6 $\frac{1}{2}$ fluidrachms]. Rub the Ammoniac, in a warmed mortar, with nine hundred cubic centimeters [or 30 fluidounces] of Water, at first very gradually added, until a uniform emulsion results. Then strain the mixture into a graduated vessel, and wash the mortar and strainer with enough Water to make the product measure one thousand cubic centimeters [or 33 fluidounces, 6 $\frac{1}{2}$ fluidrachms]." *U. S.* 1890.

Rub the Myrrh, Sugar, and Potassium Carbonate, in a mortar, with *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims] of Rose Water, at first very gradually added, so that a uniform mixture may result. Transfer this to a graduated vessel, add the Spirit of Lavender, then the Ferrous Sulphate, previously dissolved in about *fifty cubic centimeters* [or 1 fluidounce, 331 minims] of Rose Water, and, lastly, enough Rose Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the whole thoroughly. This preparation should be freshly made when wanted." U. S.

"Ferrous Sulphate, 25 grains (Imperial) or 2.5 grammes; Potassium Carbonate, 30 grains (Imp.) or 3 grammes; Myrrh, 60 grains (Imp.) or 6 grammes; Refined Sugar, 60 grains (Imp.) or 6 grammes; Spirit of Nutmeg, 50 minims (Imp. meas.) or 4.5 cubic centimetres; Rose Water, 10 fl. ounces (Imp. meas.) or 437.5 cubic centimetres or a sufficient quantity. Reduce the Myrrh to powder; add the Potassium Carbonate and Refined Sugar; triturate the mixture with a small quantity of the Rose Water so as to form a thin paste; gradually add more Rose Water and the Spirit of Nutmeg; continue the trituration and further addition of Rose Water until *seven fluid ounces* (Imp. meas.) or three hundred and six and a quarter cubic centimetres of liquid result; dissolve the Ferrous Sulphate in *three fluid ounces* (Imp. meas.) or one hundred and thirty-one and a quarter cubic centimetres of the Rose Water; mix the liquids." Br.

This is very nearly the same as the celebrated tonic or anti-heatie myrrh mixture of Griffith. The ferrous sulphate is decomposed by the potassium carbonate, with the production of potassium sulphate and ferrous carbonate, while the excess of the alkaline carbonate forms a saponaceous compound with the myrrh. The mixture is at first of a greenish color, which it loses upon exposure to the air, in consequence of the conversion of the ferrous carbonate into the ferric compound. C. A. Staples remedies this tendency by making a concentrated myrrh emulsion of such strength that one fluidrachm of it contains the amount of myrrh and potassium carbonate found in a fluidounce of the official mixture, and also a concentrated syrup of ferrous sulphate, fifteen minims of which equal one fluidounce of compound iron mixture. When the latter is called for, the emulsion, properly diluted, is put in a bottle and the requisite quantity of the iron syrup added. (*A. J. P.*, Nov. 1871.) The official solution may, however, be kept for some time without change, if the vessel in which it is contained be well closed, but the best plan is to prepare it extemporaneously. The sugar contained in it helps somewhat to retard the further oxidation of the ferrous salt, and if considerably increased in amount would act still more efficiently. The finest pieces of myrrh in lump should be selected, and rubbed down with a little

of the rose water, as the powdered myrrh of commerce is often impure, and otherwise does not make a good mixture, owing mainly to its loss of volatile oil.

This mixture is a good tonic in *debility of the digestive organs*, especially when attended with derangement of the menstrual function. Hence it is used with advantage in *chlorosis* and *hysterical affections*. It has been also much employed in the hectic fever of *phthisis* and *chronic catarrh*. It is contra-indicated by the existence of inflammation of the gastric mucous membrane.

Dose, from one-half to two fluidounces (15 to 60 Cc.) two or three times a day.

MISTURA GLYCYRRHIZÆ COMPOSITA. U. S.

COMPOUND MIXTURE OF GLYCYRRHIZA
[Brown Mixture]

(mĭs-tŭ'ŕa glŭc-ŷr-rhīzæ cōm-pōs'ĭ-tā)

Mistura Fusca; Mixture de Régisse, Fr.; Zusammengesetzte Lakritzenmixture, G.

* "Pure Extract of Glycyrrhiza, *thirty grammes* [or 1 ounce av., 25 grains]; Syrup, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Acacia, granulated, *thirty grammes* [or 1 ounce av., 25 grains]; Camphorated Tincture of Opium, *one hundred and twenty cubic centimeters* [or 4 fluidounces, 28 minims]; Wine of Antimony, *sixty cubic centimeters* [or 2 fluidounces, 14 minims]; Spirit of Nitrous Ether, *thirty cubic centimeters* [or 1 fluidounce, 7 minims]; Water, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Rub the Pure Extract of Glycyrrhiza and Acacia, in a mortar, with *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Water, until they are dissolved. Transfer the solution to a graduated vessel containing the other ingredients, and rinse the mortar with enough Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the whole thoroughly." U. S.

This is an exceedingly popular cough mixture, which was made official in the U. S. Pharmacopœia of 1850. The Sugar in the U. S. 1880 formula was replaced by Syrup in the U. S. P. 1890 and the mixture made sweeter, and the Acacia was replaced by Mucilage of Acacia. The latter change was of doubtful utility; indeed, the stability of the mixture would be improved if acacia were left out entirely; the "body" which seems to be needed could be much better supplied by the use of glycerin; in the U. S. P. (8th Rev.) acacia is used. The substitution in the official process of 1880 of pure Extract of Licorice for the former impure powdered extract was undoubtedly an improvement, although by the change the mixture has lost somewhat its original appearance, and a large proportion of the precipitate which gave it a distinctive character.

The spirit of nitrous ether is probably useful by somewhat retarding decomposition. W. L. Stephen (*A. J. P.*, 1892, 563) prefers a mixture without sediment, which he makes by rubbing into a paste half an ounce each of acacia, powdered extract of glycyrrhiza, and sugar with six fluidounces of water, heating until fluid, then adding half a fluidounce of spirit of nitrous ether, one fluidounce of wine of antimony, two fluidounces of camphorated tincture of opium, and sufficient water to make a pint. If pure extract of glycyrrhiza is used as directed by the official process the mixture is but slightly cloudy; there are no advantages in making a mixture transparent.

Dose, from one-half to one fluidounce (15 to 30 Ce.) for an adult; one fluidrachm (3.75 Ce.) for a child two years old. It should be well shaken when administered.

MISTURA GUAIACI. Br.

GUAIACUM MIXTURE

(mĭs-tŭ'ra gua'ia-ci)

Emulsion Resinæ Guaiaci; Mixture de Résine de Gayac, Lait de Gayac, *Fr.*; Guajak-Emulsion, Guajakharzmixtur, *G.*

"Guaiacum Resin, $\frac{1}{2}$ ounce (Imperial) or 10 grammes; Refined Sugar, $\frac{1}{2}$ ounce (Imp.) or 10 grammes; Tragacanth, in powder, 35 grains (Imp.) or 1.6 grammes; Cinnamon Water, 1 pint (Imp. meas.) or 400 cubic centimetres. Triturate the Guaiacum Resin with the Refined Sugar and the Tragacanth; add gradually the Cinnamon Water." *Br.*

For the changes of color which the Guaiac in this mixture undergoes, and which it produces in other substances, see *Guaiaci Resina*, p. 603. Tragacanth was substituted for acacia in the *Br. Ph.* 1898 process.

Dose, one-half to two fluidounces (15 to 60 Ce.), repeated two or three times a day, or more frequently.

MISTURA OLEI RICINI. Br.

CASTOR OIL MIXTURE

(mĭs-tŭ'ra ô'le-i ric'i-ni)

Emulsion of Castor Oil; Emulsion d'Huile de Ricin, *Fr.*; Ricinusölmixtur, *G.*

"Castor Oil, 3 fl. ounces (Imperial measure) or 75 cubic centimetres; Mucilage of Gum Acacia, $1\frac{1}{2}$ fl. ounces (Imp. meas.) or 37.5 cubic centimetres; Orange-flower Water of commerce, undiluted, 1 fl. ounce (Imp. meas.) or 25 cubic centimetres; Cinnamon Water, $2\frac{1}{2}$ fl. ounces (Imp. meas.) or 62.5 cubic centimetres. Mix the undiluted Orange-flower Water and the Cinnamon Water; place the mucilage of Gum Acacia in a mortar and to it add, alternately, in portions, the Castor Oil and the mixed Waters, with constant trituration." *Br.*

This emulsion of the British Pharmacopœia might be termed a "perfumed dose of castor

oil." W. A. Gregson commented on the inconvenience of the requirement to use mucilage of acacia for preparing this mixture, and he uses the continental method as follows: Operating on one-fourth the B. P. quantity, 75 grains of powdered acacia are introduced in a dry mortar; and 6 fluidrachms of castor oil are added (all at once), then 3 fluidrachms of water, and the whole mixed intimately; having made them perfectly homogeneous, the aqueous fluids are added in quantities of one fluidrachm or more at a time, care being taken to maintain uniformity. (*P. J.*, 1899, 50.)

Dose, from one-half to two fluidounces (15 to 60 Ce.).

MISTURA RHEI ET SODÆ. U. S.

MIXTURE OF RHUBARB AND SODA

(mĭs-tŭ'ra rhê'i êt sô'dæ)

Potion à la Rhubarbe alcaline, *Fr.*; Alkalische Rhubarbermixtur, *G.*

"Sodium Bicarbonate, thirty-five grammes [or 1 ounce av., 103 grains]; Fluidextract of Rhubarb, fifteen cubic centimeters [or 243 minims]; Fluidextract of Ipecac, three cubic centimeters [or 49 minims]; Glycerin, three hundred and fifty cubic centimeters [or 11 fluidounces, 401 minims]; Spirit of Peppermint, thirty-five cubic centimeters [or 1 fluidounce, 88 minims]; Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6 $\frac{1}{2}$ fluidrachms]. Dissolve the Sodium Bicarbonate in about four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Water. Then add the Fluidextracts, the Glycerin, and the Spirit of Peppermint, and, lastly, enough Water to make the product measure one thousand cubic centimeters [or 33 fluidounces, 6 $\frac{1}{2}$ fluidrachms]." *U. S.*

This is a preparation closely resembling one which has been used in Brooklyn, N. Y., according to the formula published by E. R. Squibb. The ingredients in the original preparation were fluidextract of ipecac 51 minims, fluidextract of rhubarb 256 minims, sodium bicarbonate 512 grains, glycerin 12 fluidounces, peppermint water 2 pints. The formula in the U. S. P. 1880 did not contain fluidextract of ipecac. The official mixture may be given to children as a stomachic and carminative.

Dose, from one-half to one fluidrachm (1.8 to 3.75 Ce.), two to three times a day.

MISTURA SENNÆ COMPOSITA. Br.

COMPOUND MIXTURE OF SENNA

(mĭs-tŭ'ra sennæ com-pōs'it-ŭ)

Black Draught; Mixture de Séné composée, *Fr.*; Zusammengesetzte Senna-Aufguss, Zusammengesetzte Sennamixtur, *G.*

"Magnesium Sulphate, 5 ounces (Imperial) or 250 grammes; Liquid Extract of Liquorice, 1 fl. ounce (Imp. meas.) or 50 cubic centi-

metres; Compound Tincture of Cardamoms, 2 *fl. ounces* (Imp. meas.) or 100 cubic centimetres; Aromatic Spirit of Ammonia, 1 *fl. ounce* (Imp. meas.) or 50 cubic centimetres; Infusion of Senna, a *sufficient quantity*. Dissolve the Magnesium Sulphate in *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Infusion of Senna; add the mixed Liquid Extract of Liquorice, Compound Tincture of Cardamoms, and Aromatic Spirit of Ammonia; and enough Infusion of Senna to produce *one pint* (Imp. meas.) or one thousand cubic centimetres of the Compound Mixture." *Br.*

This is a new form of Compound Infusion of Senna, called commonly *black draught*. We prefer the form given under *Infusum Sennæ Compositum*, as being more easily prepared and quite as efficient.

Dose (Br. Pharm.), from one to two fluid-ounces (30 to 60 Cc.).

MISTURA SPIRITUS VINI GALLICI. Br.

MIXTURE OF BRANDY

(mîs-tû'râ spir'î-tûs vî'nî gál'lî-cl)

Brandy Mixture; Mixture de Cognac, *Fr.*; Brantwelmixtur, *G.*

"Brandy, 4 *fl. ounces* (Imperial measure) or 113 cubic centimetres; Cinnamon Water, 4 *fl. ounces* (Imp. meas.) or 113 cubic centimetres; Refined Sugar, $\frac{1}{2}$ *ounce* (Imp.) or 14 grammes; Two yolks of eggs. Rub the yolks of eggs and Refined Sugar together; add the Cinnamon Water and Brandy; mix." *Br.*

This nutritious and stimulant draught is scarcely entitled to a place in the Pharmacopœia. It serves the purpose, however, of enabling the practitioner to prescribe the stimulant under an official designation.

Dose, from one to two fluidounces (30 to 60 Cc.).

MISTURÆ.

MIXTURES

(mîs-tû'ræ)

Mixtures, *Fr.*; Mixturen, *G.*; Mixtura, *Sp.*

This term should be restricted, in the language of pharmacy, to those preparations in which insoluble substances, whether solid or liquid, are suspended in aqueous fluids, by the intervention of gum arabic, sugar, yolk of egg, or other viscid matter. When the suspended substance is of an oleaginous nature, the mixture is properly called an *emulsion*, and the U. S. Pharmacopœia has recognized them by creating a special class for these. (See *Emulsa*, p. 444.) The object of these preparations is usually to facilitate the administration, to conceal the taste, or to obviate the nauseating effects of unpleasant medicines, and

their perfection depends upon the intimacy with which the ingredients are blended. Some skill and care are requisite for the production of uniform and perfect mixtures. As a rule, the body to be suspended should be thoroughly mixed by trituration with the substance intended to act as the inter-medium, before the aqueous vehicle is added. In Great Britain, and to some extent in this country, the term mixture is used indiscriminately for aqueous medicinal liquids having more than one ingredient, and for aqueous liquids which cannot be easily classified. Many of such liquids are perfectly transparent and should be in the class of Solutions.

MORPHINA. U. S.

MORPHINE

(môr-phî'nâ)

"An alkaloid obtained from Opium." *U. S.*

Morphia, *U. S.* 1870; Morphinum, Morphiūm; Morphine, *Fr. Cod.*; Morphin, *G.*; Morfina, *It., Sp.*

The U. S. Pharmacopœia no longer contains a process for the extraction of morphine; that of 1870, which has been known as Staples's process, is given in the foot-note.¹

Various processes for preparing morphine have been employed. In most of them the morphine is extracted from opium by maceration with water (either pure or acidulated), then precipitated by ammonia, and the crystals afterwards purified by the agency of alcohol, or by repeated solution in a diluted acid and precipitation. Sertürner, the discoverer of morphine, made an infusion of opium in distilled water, precipitated the morphine by ammonia in excess, dissolved the precipitate in diluted sulphuric acid, precipitated anew by ammonia, and purified by solution in boiling alcohol, and crystallization. In evaporating aqueous solutions containing morphine a temperature of 40° C. (104° F.) should not be exceeded.

Properties.—Morphine crystallizes from alcohol in the form of small, colorless, shining crystals. It is officially described as follows:

¹ "Take of Opium, sliced, *twelve troyounces*; Water of Ammonia, *six fluidounces*; Animal Charcoal, in fine powder, Alcohol, Distilled Water, each, a *sufficient quantity*. Macerate the Opium with four pints of Distilled Water for twenty-four hours, and, having worked it with the hand, again macerate for twenty-four hours, and strain. In like manner, macerate the residue twice successively with the same quantity of Distilled Water, and strain. Mix the infusions, evaporate to six pints, and filter; then add five pints of Alcohol, and afterwards three fluidounces of the Water of Ammonia, previously mixed with half a pint of Alcohol. After twenty-four hours, pour in the remainder of the Water of Ammonia, mixed, as before, with half a pint of Alcohol, and set the liquid aside for twenty-four hours, that crystals may form. To purify these, boil them with two pints of Alcohol until they are dissolved, filter the solution, while hot, through Animal Charcoal, and set it aside to crystallize." *U. S.* 1870. For other processes, see *U. S. D.*, 17th ed., 876.

"Colorless, or white, shining, rhombic prisms, or fine needles, or a crystalline powder, odorless, and having a bitter taste; permanent in the air. It loses all of its water of crystallization at 100° C. (212° F.). Soluble in 3330 parts of water, 100 parts of lime water, 168 parts of alcohol, 4464 parts of ether, 1800 parts of chloroform, 113.5 parts of amyl alcohol, and in 525 parts of acetic ether at 25° C. (77° F.); soluble in 1040 parts of water at 80° C. (176° F.), and in 76 parts of alcohol at 60° C. (140° F.); insoluble in benzene. When heated to about 200° C. (392° F.) it assumes a brown color, and then melts at 254° C. (489.2° F.). Upon ignition, it is slowly consumed without leaving a residue. Its aqueous solution shows an alkaline reaction to red litmus paper. Sulphuric acid (free from nitrous compounds) added to Morphine produces no color or only a slight yellowish tint, but on heating, a brown color is developed. Sulphuric acid containing a crystal of potassium iodate gives with Morphine a dark brown color. (Codeine yields a moss-green color, changing to brown, and *narcotine* a cherry-red color.) Sulphuric acid containing a trace of selenous acid gives with Morphine a blue color, changing to green and then to brown. (Codeine yields a green color, changing to blue, and afterwards to grass-green; *narcotine* gives a green color, changing to brown, and then to cherry-red.) Nitric acid produces with Morphine an orange-red color fading to yellow (difference from *quinine*). Sulphuric acid containing a trace of molybdic acid gives a purple color, changing to blue. Sulphuric acid containing in each Cc. one drop of solution of formaldehyde yields an intense purple color. Mercuric potassium iodide T.S. produces in a solution of Morphine a white gelatinous precipitate. A solution of sodium phosphomolybdate (1 in 20) produces in solutions of Morphine a yellow precipitate soluble in ammonia water. Sulphuric acid containing a crystal of potassium dichromate gives no color at first, but after a time a green color (absence of *strychnine*, which yields a purple color, or of *acetanilide*, which gives a crimson color, changing to green). Morphine solutions, when heated with an aqueous solution of potassium ferrieyanide containing a drop of neutral ferric chloride solution, give a deep blue solution, from which, after standing, a blue precipitate separates (difference from *codeine*). If 0.1 Gm. of Morphine be dissolved in 10 Cc. of diluted hydrochloric acid, no red coloration should be produced by the addition of a few drops of ferric chloride T.S. (absence of *meconic acid* or *meconates*). If to a neutral solution of Morphine (1 in 100), made by the careful addition of diluted sulphuric acid, a few drops of ferric chloride T.S. be added, a blue color will be produced, which is destroyed by acids, alcohol, or by heating. On adding 4 Cc. of potassium hydroxide T.S. to 0.2 Gm. of Morphine, a clear, colorless solution, free from any undissolved residue, should result (ab-

sence of, and difference from, various *other alkaloids*), and no odor of ammonia should be noticeable (absence of *ammonium salts*)." U. S.

Von Gerichten and Schrötter (*Ber. d. Chem. Ges.*, 1882, pp. 1484 and 2179) showed that morphine and codeine were derivatives of phenanthrene, as when distilled with zinc dust they yielded phenanthrene, pyridine, and quinoline. Knorr (*Ber. d. Chem. Ges.*, 22, p. 2081) has shown that it is probable that morphine contains, combined with the phenanthrene nucleus, the *morpholine* group. Morpholine (tetrahydro-oxazine), $\text{NH} < \begin{smallmatrix} \text{CH}_2\text{CH}_2 \\ \text{CH}_2\text{CH}_2 \end{smallmatrix} > \text{O}$, is formed

when dioxyethylamine is heated to 160° C. with hydrochloric acid, or is boiled with alkali. As seen from the formula, it bears a structural relation to both pyrrol and pyridine. For later views on the structure of the morphine molecule by Knorr and Vis, see *Proc. A. Ph. A.*, 1894, 1122. For a chemical bibliography of morphine, by H. E. Brown, see *Ph. Rev.*, 1897, and *Ph. Archiv.*, 1898.

Heated in the open air, morphine burns with a bright flame, and at a red heat is wholly dissipated. In the products resulting from the combustion of opium or morphine this alkaloid may be detected, proving that it is partly volatilized when burned. (Deschamnes, *A. G. N.*, Fév. 1855, 240.) Morphine in solution is to a considerable extent absorbed by animal charcoal, which, though it will part with most of the alkaloid to alcohol, cannot be wholly deprived of it by repeated washings with that liquid, either cold or hot. (Lefort, *J. P. C.*, Août, 1861, 98.) Its solution restores the blue color of litmus paper reddened by acids, and turns the yellow of turmeric to brown. Hager (*Ph. Ztg.*, 93, 250, also *Proc. A. Ph. A.*, 1893, 680) states that on heating solutions containing morphine, oxygen is absorbed gradually and oxymorphine is formed; at a boiling temperature this change proceeds rapidly. The oxymorphine is much less active as a narcotic than is morphine. This absorption of oxygen takes place most rapidly in alkaline solutions and is also affected by the aid of potassium permanganate, potassium ferrieyanide, and ammoniacal copper solution. The reaction is:

This product is known as *oxymorphine* (or *pseudomorphine*). Morphine is, therefore, a powerful reducing agent, acting upon silver nitrate and gold chloride even in cold solutions. With the acids morphine forms salts, which are generally soluble, and are decomposed by the alkalies. It is dissolved also by the fixed and volatile oils. The solutions of potassium and sodium hydroxides also dissolve morphine, which is precipitated slowly from them on exposure to the air, in consequence of the absorption of carbon dioxide. Solution of ammonia has to a certain extent the same solvent power, and hence the necessity, in precipitating morphine by this alkali, not to employ it in great

excess. Solution of iodine with potassium iodide precipitates the salts of morphine in aqueous solution. With chlorine water morphine and its salts assume an orange color, and the same effect is produced on them by solution of chlorinated soda. (Fairthorne, *A. J. P.*, xxviii. 9.) By the contact of nitric acid they assume a blood red color, which ultimately changes to yellow, and this is one of the tests of morphine; but, as the same change of color is produced with brucine and impure strychnine, it cannot be relied on in the absence of other evidence. Nitric acid also produces a red color with oil of cloves, but in this case the red does not change to yellow. When added to a solution of iodic acid, or an acidulous iodate, morphine and its salts redden the liquid and set iodine free. (Sérullas.) This is a very delicate test, but is not conclusive, as various other organic substances act in a similar manner. J. Lefort, however, has found that the color produced by these substances is removed by ammonia, while the redness produced with morphine is greatly intensified by addition of that alkali. This test, thus modified by the addition of ammonia, is so delicate that, according to Lefort, it will detect one part of morphine in 10,000 parts of a liquid holding it in solution. (*J. P. C.*, Août, 1861, 113.)¹ Husemann's test consists in leaving morphine or its salt in contact with concentrated sulphuric acid for 12 or 15 hours, or in heating for half an hour with the acid to 100° C. (212° F.), and then adding either a little nitric acid, a nitrate or chlorate or chlorine water, or chlorinated soda, when a beautiful bluish or reddish-violet color, passing into deep blood-red and gradually paling, is developed. The presence of small quantities of coloring matter does not prevent this reaction, if chlorinated reagents are selected. A. Husemann asserts that this test will recognize the hundredth part of a milligramme of the alkaloid. (*A. J. P.*, xlvii. 210.) According to R. Schneider, a very delicate test is afforded by putting a drop of the suspected liquid on a plate, saturating with sugar, and putting alongside of it a drop of sulphuric acid; if morphine be present, a very intense purple will be developed at the point of contact, passing after half an hour into violet, then bluish green, and finally dirty yellow. (*J. P. C.*, 4e sér., xviii. 221.) According to H. Weppen, the delicacy of this test is much increased by

the addition of a minute quantity of bromine water to the solution. Codeine and aconitine are stated, however, to give the same reaction. (*Ibid.*, 4e sér., xix. 246.)

Fröhde's reagent (a fresh solution of .005 Gm. sodium molybdate in 1 Cc. of pure concentrated sulphuric acid) strikes with morphine and its salts a beautiful blue-violet color, passing into blue, then green, finally back to bluish violet. This reaction is stated to be delicate but not characteristic. A. B. Prescott gave a thorough résumé of the views of investigators on this test in *A. J. P.*, 1876, 59. Bruylants combines Fröhde's test with that of Husemann. A trace of Fröhde's reagent added to a solution of morphine in sulphuric acid produces the well-known lilac tint; if the sulphuric acid solution be warmed and treated in the same way, a green tint will be noted. On dropping a particle of potassium nitrate into this green liquid, the color changes to red and finally yellowish. The other opium alkaloids give different tints. (*Proc. A. Ph. A.*, 1895, 1016.) In the presence of sulphuric acid morphine exhibits surprising powers as a reducing agent. Among the most notable instances of deoxidation may be mentioned those of silver oxide, hydrated bismuth oxide, the acids of tin, tungsten, vanadium, titanium, and molybdenum. A solution of titanate acid in concentrated sulphuric acid is one of the most delicate reagents for morphine. An intense brown-red to violet color is produced if titanate acid is added to concentrated sulphuric acid containing a trace of morphine in solution. (Flückiger, *N. R.*, Feb. 1880. See, also, *N. R.*, 1881, p. 237.) M. H. Kahlbrunner states that the most sensitive test is made with a solution (No. 1) of crystallized ferric chloride (thirty grains to four fluidrachms of distilled water) and a fresh solution (No. 2) of potassium ferri-cyanide (two grains in four drachms). To the suspected liquor five or six drops of No. 1 are added, and afterwards three or four drops of No. 2. If morphine be present, a color varying from deep blue to pale blue and bluish green, according to the proportion of the alkaloid, is developed. Neither gum, sugar, alcohol, glycerin, atropine, quinine, nor strychnine interferes with this test. An excess of alkali does so by decomposing the ferric chloride. This test depends upon the fact that the potassium ferri-cyanide solution is reduced by morphine to the ferrocyanide. It is affirmed that even 1-60,000th of one per cent. of morphine can be detected. (*Ibid.*; see also *Proc. A. Ph. A.*, 1897, 701.) G. Vulpius (*A. Pharm.*, 1887, 25) states that if about 0.00025 Gm. of a morphine salt be dissolved in a porcelain dish in about six drops of concentrated sulphuric acid, a few centigrammes of sodium phosphate added, and the mixture carefully heated, white fumes will be evolved and a violet color appear. On adding water drop by drop, a brilliant red appears, which, on further addition, changes to a dirty green. If the solution be then

¹ *Stas's Method of Extracting the Alkaloids from Mixtures.*—To separate the alkaloid from foreign matters, the mixture is treated alternately with water and alcohol in different degrees of concentration; the liquors thus obtained are filtered; tartaric or oxalic acid, but preferably the former, is added in excess; the mixture is heated to 71.1° or 76.6° C. (160° or 170° F.); the whole is placed upon a filter; the deposited matter is washed with concentrated alcohol; the alcoholic solution is evaporated at a temperature not exceeding 35° C. (95° F.); the residue is introduced into a small bottle; a solution of potassium or sodium hydroxide is added, little by little, and afterwards four or five times the measure of ether; the mixture is shaken and then allowed to stand; and, finally, the ether is decanted, and yields the alkaloid by spontaneous evaporation.

shaken with the same volume of chloroform, the latter will be colored blue. Isobutylic alcohol has been used by Nagelvoort for the detection of morphine and codeine. (See *Proc. A. Ph. A.*, 1894, 273.)

Siebold heats gently the suspected substance with some drops of concentrated sulphuric acid and a small quantity of chemically pure potassium perchlorate; a deep brown color will be produced if morphine is present. (*P. J.*, Oct., 1873.) According to H. S. Wellcome, one part of morphine in ten thousand parts of water can be recognized by chlorine water, if care be exercised not to decolorize by an excess of the reagent; the color varies from light orange-red to deep red according to the proportion of morphine present. Brucine is the only other alkaloid giving the same reaction, but, while the color produced by morphine is discharged by excess of chlorine, that caused by brucine is not affected. (*A. J. P.*, 1874, p. 305.) To discover morphine in the presence of quinine, see *Ibid.*, p. 361. Morphine and its salts assume a fine blue color with ferric chloride; at least this is true of the alkaloid, its sulphate, acetate, and oxalate, and the same effect will be produced by the other salts, if previously decomposed by an alkali, but that this test should be satisfactory it is necessary to operate on morphine either in powder or in concentrated solution. (Lefort.) A solution of morphine acetate or sulphate containing only one part of the salt in 100 precipitates silver from a solution of the nitrate of that metal. (Horsley.) Morphine is precipitated from its solutions by potassium or sodium hydroxide, and redissolved by an excess of the alkali. Infusion of galls and other vegetable substances containing tannic acid precipitate morphine in the state of a tannate, which is soluble in acetic acid, but according to Dublanc, the alkaloid is not precipitated by pure gallic acid. If ammonia be added to a mixture of the solutions of chlorine and morphine, there will be produced a dark brown color, which will be destroyed by a further addition of chlorine. For methods of separating narcotine, see U. S. D., 17th ed., 879.

The proportion of pure morphine which Turkey opium is capable of affording varies from 9 per cent., or less, to 20 per cent., according to the quality of the drug; but much less than the least quantity mentioned is often obtained, in consequence of the incomplete exhaustion of the opium, the loss in the process for preparing it, the destructive action of heat, or inferiority in the quality of the drug. (See *Opium*.) Formaldehyde reacts with both morphine and codeine to form medicinally active condensation products by the union of two molecules of the base with one molecule of the formaldehyde, with elimination of water; a methylene group CH_2 uniting with two alkaloidal residues each of which loses an H atom. That formed from morphine is an amorphous

base, difficultly soluble in water but easily soluble in alkaline solution and in alcohol. It melts at 270°C ., and forms a hydrochloride soluble in water. (*Proc. A. Ph. A.*, 1897, 702.)

Uses.—There can be no doubt that morphine is the chief narcotic principle of opium, from which, however, it differs somewhat in its mode of action. In consequence of its insolubility in water, morphine in its pure state is less convenient than its salts, which are therefore always preferred. The acetate, sulphate, and hydrochloride, which have been employed, act precisely alike therapeutically, and differ from opium chiefly in being less disposed to constipate the bowels. They are also somewhat less likely to cause disagreeable after-effects than is opium, but the deodorized tincture is certainly preferable to them for many purposes. They are further adapted for hypodermic use.¹ Oleic acid has also been proposed as a vehicle for morphine externally used, as it dissolves both the alkaloid and its salts perfectly in considerable proportion. A liniment of oleate of morphine has been proposed, consisting of 300 parts of oleic acid and 1 part of morphine, scented with a little oil of bergamot. (*Ibid.*, xxvi. 302.)

The toxicology of morphine is identical with that of opium.

As the proportion of acid necessary to neutralize morphine is very small, the dose of the alkaloid is practically the same as that of its salts.

Dose, one-fifth of a grain (0.012 Gm.), equivalent to a grain of powdered opium.

MORPHINÆ ACETAS. U. S., Br.

MORPHINE ACETATE

(môr-phî'næ æ-cē'tās)

"The acetate [$\text{CH}_3\text{COOH} \cdot \text{C}_{17}\text{H}_{19}\text{NO}_3 + 3\text{H}_2\text{O}$] of the alkaloid morphine should be kept in well-stoppered, dark amber-colored vials; a minute quantity of free acetic acid should be present to prevent decomposition." U. S.

¹ *Morphine Lactate* ($\text{C}_{17}\text{H}_{19}\text{NO}_3 \cdot \text{C}_3\text{H}_5\text{O}_2$).—This salt crystallizes in four-sided prisms, one part being soluble in eight parts of water and ninety-three parts of alcohol. (*P. J.*, 1886, 958.)

Morphine Hydrocyanide.—J. M. Maisch noticed that when a soluble salt of morphine is added to a solution of soluble cyanide, crystals of morphine hydrocyanide form. This salt, although sparingly soluble in water, is freely dissolved by that liquid when acidulated. It is evident that potassium cyanide and morphine should not be prescribed together in solution, except in connection with free acid.

Morphine Hydrobromide, or *Morphine Bromide* ($\text{C}_{17}\text{H}_{19}\text{NO}_3 \cdot \text{HBr} + 2\text{H}_2\text{O}$), is made by double decomposition between morphine sulphate and barium bromide. (*A. J. P.*, xlv. 447.)

Morphine Phthalate is made by adding pure morphine to a hot solution of absolutely pure phthalic acid as long as it is dissolved, filtering, and evaporating. One part of the salt is soluble in five parts of water. The solutions are perfectly neutral, and have been especially recommended by E. Bombeloni for hypodermic use. (See article in *Ph. Ztg.*, 1887, 488.)

"The carefully dried salt, $C_{17}H_{19}NO_3 \cdot C_2H_4O_2$, $3H_2O$, obtained by neutralizing morphine with acetic acid." *Br.*

Morphinæ Acetas, *Br.* 1867, *U. S.* 1870; Acetate of Morphia; Morphinum Aceticum; Acetas Morphicus; Acétate de Morphine, *Fr.*; Essigsäures Morphinum; Morphinacetat, *G.*

A process for this salt is no longer official; that of the *U. S. P.* 1870 is appended.¹

In the *U. S.* process of 1870, morphine is saturated with acetic acid. A small excess of acid is attended with no inconvenience, as it is subsequently driven off by the heat. Care is required not to employ too much heat in the evaporation, as the acetate is easily decomposed, a portion of the acetic acid escaping, and leaving an equivalent portion of uncombined morphine. With attention to arrest the evaporation at a certain point, the acetate may be obtained in the state of crystals, but the crystallization is attended with some difficulty, and evaporation to dryness is almost universally preferred. Some recommend to dissolve the morphine in boiling alcohol, instead of suspending it in water, previously to the addition of the acetic acid. Less heat is thus required in the evaporation, and impurities in the morphine may often be detected, as they are likely to be insoluble in alcohol. To ascertain, in this case, whether the morphine is saturated, it is necessary to employ litmus paper, the blue color of which should not be restored if previously reddened by an acid. If the morphine used in preparing the acetate contain narcotine, it will be best to employ diluted acetic acid as the solvent, and to favor its solvent power by heat. Under these circumstances it dissolves only the morphine, leaving the narcotine nearly or quite untouched. (Hodgson, *A. J. P.*, v.) The British process (1885) differs from that of the *U. S. Pharmacopœia* of 1870 only in obtaining uncombined morphine, as the first step, by precipitating it from a solution of the hydrochloride, morphine itself not being official.

Properties.—It is officially described as "a white, or yellowish-white, crystalline or amorphous powder, having a faintly acetous odor, and a bitter taste. It gradually loses acetic acid when exposed to air, and becomes less soluble in water. Soluble in 2.25 parts of water, 21.6 parts of alcohol, 480 parts of chloroform, and in 5.2 parts of glycerin at 25° C. (77° F.); soluble in 2 parts of water at 80° C. (176° F.), and in 2.5 parts of alcohol at 60° C. (140° F.); insoluble in ether. When heated, the salt loses water and acetic acid, and melts at about 200° C. (392° F.). When

ignited, it is consumed completely, leaving no residue. The addition of diluted ammonia water in slight excess to an aqueous solution of Morphine Acetate causes a white precipitate, which, when collected and washed, should conform to the reactions and tests given under *Morphina*. On adding sulphuric acid to the salt, vapors of acetic acid are evolved. Ferric chloride T.S. produces, in neutral aqueous solutions of the salt, a blue color, destroyed by acids, alcohol, or by heating. The color tests for the identification of Morphine Acetate and those showing the absence of impurities are identical with those described under *Morphina*." *U. S.* "A white crystalline or amorphous powder, almost entirely soluble in 2½ parts of water and in about 100 parts of alcohol (90 per cent.). It loses acetic acid when exposed to the air. It affords the reactions for morphine mentioned under '*Morphinæ Hydrochloridum*,' and the reactions characteristic of acetates. 2 grammes of the salt form with 6 cubic centimetres of warm *morphinated water* a slightly turbid solution, which is rendered clear by the addition of 0.1 cubic centimetre of *acetic acid*; and this solution, when mixed with *solution of ammonia* in slight excess, yields a precipitate which, after washing and drying as described under '*Morphinæ Hydrochloridum*,' weighs 1.42 grammes. If the salt yield a larger proportion of morphine than this, it should be recrystallized from hot water acidulated with *acetic acid*. Heated to redness with free access of air, it leaves no residue (absence of mineral impurities)." *Br.* Morphine acetate crystallizes in slender needles united in fasciculi. As ordinarily obtained by evaporation to dryness, it is not entirely soluble in water, a portion of it being uncombined morphine. To render it soluble, all that is necessary is to add a little acetic acid.

Uses.—This and the other official salts of morphine are of identical medicinal value. They are almost invariably preferred to the alkaloid itself, and are given by the mouth, in pill or solution, in doses of from one-eighth to one-half grain (0.008 to 0.032 Gm.). They are employed externally, sprinkled on blistered surfaces, and are very frequently exhibited by subcutaneous injection, but great caution must be observed that they are not thrown into a vein. We have seen one-sixth of a grain, thus given, produce almost instantaneous insensibility, with dropping of jaw, and other evidence of immediate death, from which the patient was saved with difficulty. When given hypodermically fifteen minutes before the anæsthetic, the morphine salt was found by Claude Bernard to prolong and intensify the anæsthesia in animals, and many surgeons have employed it in man in this way, with satisfactory results. The solutions for hypodermic use should be freshly prepared, as morphine salts, especially the acetate, are very prone to undergo decomposition, through the growth of a fungus.

¹ *Morphinæ Acetas*, *U. S.* 1870.—"Take of Morphia, in fine powder, a *trovounce*; Distilled Water *half a pint*; Acetic Acid a *sufficient quantity*. Mix the Morphia with the Distilled Water; then carefully drop Acetic Acid into the mixture, stirring it constantly until the Morphia is neutralized and dissolved. Evaporate the solution, by means of a water-bath to the consistence of syrup, and set aside until it concretes. Lastly, dry the salt with a gentle heat, and rub it into powder."

Dose, one-eighth to one-half grain (0.008 to 0.032 Gm.).

MORPHINÆ HYDROCHLORIDUM.

U. S., Br.

MORPHINE HYDROCHLORIDE

[Morphinæ Hydrochloras, Pharm. 1890, Morphine Hydrochlorate]

(mōr-phī'næ hŷ-dro-phlō'rī'dūm)

"The hydrochloride [$\text{HCl} \cdot \text{C}_{17}\text{H}_{19}\text{NO}_3 + 3\text{H}_2\text{O}$] of the alkaloid morphine should be kept in well-stoppered, amber-colored vials." U. S.
"The hydrochloride, $\text{C}_{17}\text{H}_{19}\text{NO}_3 \cdot \text{HCl} \cdot 3\text{H}_2\text{O}$, of an alkaloid obtained from opium." Br.

Morphinæ Muriat. Br. 1867. U. S. 1870; Muriat (Hydrochloras) Morphiæ; Morphiæ Hydrochloras; Muriat of Morphia; Chlorhydrate de Morphine, Fr. Cod.; Morphinum Hydrochloricum, P. G.; Morphin-hydrochlorid, Salzaures Morphin, G.

A process for this salt is no longer official; that of the U. S. P. 1870 is appended.¹ The British process (1885) will be found in U. S. D., 17th ed., 882.

Properties.—This salt crystallizes in "white, silky, glistening needles or microcrystalline cubes, or a white, crystalline powder, odorless, and having a bitter taste; permanent in the air. It loses its water of crystallization at 100° C. (212° F.). Soluble in 17.2 parts of water, and in 42 parts of alcohol at 25° C. (77° F.); soluble in 0.5 part of water at 80° C. (176° F.), and in 35.5 parts of alcohol at 60° C. (140° F.); insoluble in ether and in chloroform. When heated to 250° C. (482° F.), it assumes a brown color, and on higher heating, chars without melting. On ignition, it is slowly consumed, leaving no residue. Its aqueous solution is neutral to litmus paper. On shaking an aqueous solution of the salt with diluted ammonia water in slight excess, a crystalline precipitate is formed, which, when collected and washed, should respond to all tests and reactions given under *Morphina*. Silver nitrate T.S. produces a white precipitate, insoluble in nitric acid. Ferric chloride T.S. produces, in neutral aqueous solutions of the salt, a blue color, which is destroyed by acids, alcohol, or by heating. On adding potassium carbonate T.S. to a solution of the salt (1 in 30), a white precipitate should be formed, which should dissolve in chloroform without color (absence of *apomorphine*). The color tests for the identification of Morphine Hydrochloride and those showing the absence of impurities are identical with those described under *Morphina*." U. S. "Acicular prisms of a

silky lustre, or a white powder consisting of minute cubical crystals, unchanged by exposure to the air. Soluble in 24 parts of cold water, 1 part of boiling water, and in 50 parts of alcohol. It should be without action on litmus. Solution of ammonia causes a white precipitate in the aqueous solution, with difficulty soluble in excess; solution of potassium hydroxide a similar precipitate readily soluble in excess. This precipitate yields mere traces to benzol (absence of other alkaloids). Moistened with nitric acid the salt yields an orange-red coloration; with test-solution of ferric chloride a dull greenish-blue coloration. Heated on a water-bath for ten or fifteen minutes with a few drops of sulphuric acid, cooled, and treated with a few drops of diluted nitric acid, it gives a violet color rapidly passing to blood-red. It dissolves without coloration in strong sulphuric acid; the addition of a small quantity of sodium arsenate to a portion of this solution causes a bluish-green coloration, and a small quantity of bismuth oxynitrate added to another portion gives a purplish-brown coloration. It affords the reactions characteristic of hydrochlorides. 2 grammes of Morphine Hydrochloride dissolved in 250 cubic centimetres of warm morphinated water, with solution of ammonia added in the slightest possible excess, will give on cooling a crystalline precipitate which, when washed with a little cold morphinated water and dried, should weigh 1.51 grammes. The drying should be accomplished, first by pressing the precipitate between sheets of bibulous paper, then by exposing it to a temperature between 131° and 140° F. (55° and 60° C.), and finally to a temperature of 230° F. (110° C.) for twenty minutes. Heated to redness with free access of air, it burns, leaving no residue (absence of mineral impurities)." Br. A saturated solution in boiling water forms a solid crystalline mass on cooling. The solution of morphine hydrochloride, when kept several months, has been known to produce vomiting, through the formation of traces of apomorphine. (*Ph. Centralh.*, 1885, 93.) The salt may be known to be a hydrochloride by responding to the official test with silver nitrate. Potassium hydroxide throws down from its solution a precipitate which is redissolved by an excess of the alkali. The salt is affected by heat, nitric acid, iodic acid, ferric chloride, and chlorine followed by ammonia, in the same manner as morphine. Sugar is said to have been used largely in the adulteration of this salt. It may be detected most readily by the deep red color produced when the adulterated salt is dissolved in strong sulphuric acid. (See *Saccharum*.)

This preparation of morphine is much used in Great Britain, but in this country less than either the sulphate or the acetate. For medicinal properties, see *Morphina*.

Dose, one-eighth to one-half grain (0.008 to 0.032 Gm.).

¹ "Take of Morphia, in fine powder, a troyounce; Distilled Water four fluidounces; Muriatic Acid a sufficient quantity. Mix the Morphia with the Distilled Water; then carefully drop in Muriatic Acid, constantly stirring, until the Morphia is neutralized and dissolved. Evaporate the solution, by means of a water-bath, so that on cooling it may crystallize. Lastly, drain the crystals, and dry them on bibulous paper." U. S. 1870.

MORPHINÆ SULPHAS. U. S.

MORPHINE SULPHATE

(môr-phī'næ sŭl'phās)

"The sulphate $[SO_2(OH)_2 \cdot (C_{17}H_{19}NO_3)_2 + 5H_2O]$ of the alkaloid morphine should be kept in well-stoppered, amber-colored vials." *U. S.*

Morphinæ Sulphas, *Br.* 1867, *U. S.* 1870; Morphinum Sulphuricum, Sulphas Morphinicus; Sulphate of Morphia; Sulfate de Morphine neutre, *Fr. Cod.*; Schwefelsäures Morphinum, Morphinsulfat, *G.*; Sulfato morfico, *Sp.*

No process is given in the present *U. S. P.*; that of the *U. S. P.* 1870 is appended.¹ Morphine sulphate is no longer official in the British Pharmacopœia 1898, the hydrochloride being used in Great Britain as in Germany almost exclusively.

In the process of 1870 the morphine is known to be saturated when it is wholly dissolved by the water. To ascertain whether the acid is added in excess, litmus paper may be resorted to. If the morphine employed contain narcotine, this will remain in the mother liquor, and will not contaminate the product. The mother liquor remaining after the first crystallization may be evaporated so as to afford a fresh supply of the sulphate, but, if the morphine was not originally quite pure, the second product will contain the impurities, and should not be used till it has undergone further purification. When impure morphine is employed, the mother liquor should be mixed with alcohol, or boiled with purified animal charcoal and filtered, and then decomposed by ammonia, which will precipitate the morphine; or the mother liquor may be mixed with a little milk of lime, filtered, and precipitated with solution of ammonium chloride, when the morphine will be nearly pure. This may be converted into the sulphate in the manner directed by the Pharmacopœia.

Another mode of obtaining morphine sulphate is to dissolve the alkaloid in boiling alcohol of 36° Baumé (sp. gr. 0.8428), saturate it while hot with sulphuric acid, add purified animal charcoal, boil for a few minutes, and filter the solution at the boiling temperature. Upon cooling, it deposits most of the sulphate, and the remainder may be

obtained by evaporating the mother liquor. According to J. Calvert (*Pac. Drug.*, June, 1893) morphine sulphate is made as follows: Opium in any quantity is exhausted with water; the resulting liquid is precipitated with an alkaline base and crude morphine is the result. The crude morphine is dissolved in diluted sulphuric acid, the solution filtered through animal charcoal and evaporated to a density of 4½° to 5° B. The crystallizing apparatus is a leaden tank, about six inches in depth, of any size to correspond with the amount of morphine sulphate. It is hinged on a frame and has an outlet, with a plug or faucet at the lower end for drainage. The solution being ready and the apparatus adjusted, the hot solution is run into the crystallizer; the solution is stirred gently every few minutes until crystals commence to form on the surface, and then, by carefully stirring, when the solution has come to the right temperature, the morphine sulphate crystallizes suddenly into a solid mass. The mass of crystals is allowed to repose for 48 hours, the plug at the lower end of the tank is removed and the mother liquor is allowed to run off, at first slowly, and afterwards by elevating the tank the last of the liquor is removed; the drainage requires several days. The crystals in the apparatus are then cut up into pieces of the shape of bricks (commencing at the upper end), which are placed on an absorbent, and removed to a drying-room. In ordinary crystallization a certain part of the coloring matter is retained in the crystals. In this case, when the morphine is crystallized as described, and dried in bricks, nearly all the retained coloring matter comes to the surface, so that when the bricks come out of the drying-room the surfaces are brown, and in some cases almost black, showing that the coloring matter is eliminated. The next part of the process is to remove the colored part. This is effected by slicing off the dark portions, leaving the morphine sulphate perfectly white. The masses of crystals of morphine sulphate (which have been heretofore described as bricks) are in a condition to be made into a merchantable article. A very sharp knife and delicate handling is used. The bricks are placed on a table and cut into slices each measuring about ¼ inch. These slices are very gently crumbled in the hands or they are preferably cut into cubes or small pieces to distinguish them from other white crystals of a less poisonous nature.

In the evaporation of the solution of this salt, care should be taken not to carry the heat too far, for, when pushed to incipient decomposition with an excess of acid, a new substance is formed containing no morphine. This salt is sometimes adulterated. D. B. Dott met with a sample in the English market which contained 34.63 per cent. of anhydrous sodium sulphate. (*P. J.*, August 4, 1877.)

Properties.—It is officially described as in "white, feathery, acicular, silky crystals, or in

¹ "Take of Morphia, in fine powder, a troyounce; Distilled Water half a pint; Diluted Sulphuric Acid a sufficient quantity. Mix the Morphia with the Distilled Water, then carefully drop in Diluted Sulphuric Acid, constantly stirring until the Morphia is neutralized and dissolved. Evaporate by means of a water-bath, so that on cooling it may crystallize. Lastly, drain the crystals, and dry them on bibulous paper." *U. S.* 1870.

cubical masses, odorless, permanent in the air, and having a bitter taste. It loses three molecules of water of crystallization at 100° C. (212° F.), and the remaining two at 130° C. (266° F.). Soluble in 15.3 parts of water, and in 465 parts of alcohol at 25° C. (77° F.); soluble in 0.6 part of water at 80° C. (176° F.), and in 187 parts of alcohol at 60° C. (140° F.); insoluble in ether and chloroform. When heated to about 250° C. (482° F.), the salt assumes a brown color, and then chars without melting. When ignited, it is very slowly consumed, leaving no residue. Its aqueous solution is neutral to litmus paper. On adding a dilute solution of ammonia water in slight excess to its aqueous solution, and vigorously shaking the liquid, a precipitate is formed, which when collected and washed, should respond to all the tests and reactions given under *Morphina*. Barium chloride T.S. produces a white precipitate, insoluble in hydrochloric acid. Ferric chloride T.S., when added to neutral aqueous solutions of the salt, produces a blue color, which is destroyed by acids, alcohol, or by heating. The color tests for the identification of Morphine Sulphate, and those showing the absence of impurities, are identical with those described under *Morphina*. U. S. By exposure to a heat of 120° C. (248° F.) it loses 9.66 parts of the water, but cannot be deprived of the remainder without decomposition. (Liebig.) The official tests for it are those for sulphuric acid and for morphine. Considerable discussion has taken place in the pharmaceutical journals about the solubility in water of morphine sulphate. Owing to the ease with which the salt parts with its water of crystallization, even at ordinary temperatures, it is not difficult to account for some of the discrepancies that exist in the text-books on this subject. Yet there can be no doubt that the heretofore commonly quoted solubility, "twice its weight of cold water," is an oft-repeated error. J. U. Lloyd (*N. R.*, May, 1882) found it soluble in 21.60 parts of cold water. F. B. Power, after a determination by precipitation with barium chloride, found a commercial specimen of undoubted purity to require very nearly 24 parts of cold water, and the U. S. P. 1880 adopted his results. (*A. J. P.*, 1882, p. 97.) Virgil Coblentz subsequently examined five commercial samples, and practically confirmed Power's results, finding the specimens soluble respectively in 21.38, 23.90, 23.18, 17.69, and 18.97 parts of water. D. B. Dott criticises the methods employed by J. U. Lloyd, and to some extent those of Power, but fails to establish a very different result. (*P. J.*, 1882, p. 252.) The temperature used in obtaining these figures was 15.6° C. The solubility according to the U. S. P. (8th Rev.) is 15.3 parts of water at 25° C. (77° F.).

The solution of morphine sulphate formerly official was made by dissolving 1 grain of morphine sulphate in 1 fluidounce of distilled water,

and, although the solution is more stable than that of any other of the morphine salts in common use, it will in time become weakened through the presence of microscopic plants belonging to the *Confervoideæ*, and hence it is not desirable to keep it on hand. According to Hamberg of Stockholm, the sulphate should be dissolved in boiling distilled water which is free from ammonia, phosphoric, nitric, and nitrous acids; the solution should be filtered through paper not previously moistened, and is best preserved in small well-filled vials closed with a glass stopper. (*Ph. Ztg.*, No. 49; *A. J. P.*, 1881.) For medicinal properties, see *Morphina* and *Morphinæ Acetas*, pp. 785, 788.

Dose, from one-eighth to one-half grain (0.008 to 0.032 Gm.), which may be given in pill or in solution.

MORPHINÆ TARTRAS. Br.

MORPHINE TARTRATE

(môr-phī'næ tār'trās)

Morphinum Tartaricum; *Tartrate de Morphine*, Fr.; *Morphintartrat*, Weinsaures Morphinum, G.

"Morphine Tartrate, $(C_{17}H_{19}NO_3)_2C_4H_6O_6, 3H_2O$, may be prepared by the combination of morphine and tartaric acid in molecular proportions." Br.

This salt of morphine has been introduced into the British Pharmacopœia 1898; it was brought into notice by Erskine Stuart (1880), and recommended for hypodermic injection because of its greater solubility in water over the other salts of morphine. (See *Injectio Morphinæ Hypodermica*, p. 658, and *Liquor Morphinæ Tartaratis*, p. 727.) It is officially described as "a white powder consisting of fine nodular tufts of minute acicular crystals. Efflorescent at 68° F. (20° C.). Soluble in 11 parts of cold water, almost insoluble in alcohol (90 per cent.). It affords the reactions characteristic of morphine and of tartrates. 2 grammes dissolved in 20 cubic centimetres of warm morphinated water, with solution of ammonia added in the slightest possible excess, will give, on cooling, a crystalline precipitate which, after washing and drying as described under 'Morphinæ Hydrochloridum,' should weigh 1.47 grammes. Heated to redness with free access of air, it burns without leaving any residue (absence of mineral impurities)." Br. A. E. Tanner (*P. J.*, 1903, 134) found morphine tartrate in the English market of slow solubility; he investigated the subject and stated that an acid tartrate of morphine was sparingly soluble, that this was found in commerce and that it required 100 parts of cold water for its solution.

Uses.—Morphine tartrate is used for making hypodermic injections. See *Morphina*.

Dose, one-eighth to one-half grain (0.008 to 0.032 Gm.).

MOSCHUS. U. S., Br.

MUSK

(mŏs'phŭs)

"The dried secretion from the preputial follicles of *Moschus moschiferus* Linné." U. S.
"The dried secretion from the preputial follicles of *Moschus moschiferus*, Linn." Br.

Moschus *Orientalis*, M. *Chinensis*, M. *Tibetanus*; Chinese, Thibet or Tonquin Musk; Musc. Fr. *Od.*; Balsam, *Moschus*, G.; Muschio, It.; Alimzicle, Sp.

Moschus moschiferus, Gmelin, *Syst. Nat.* i. 172; *Rees's Cyclopædia*.—This animal bears a close resemblance to the deer in shape and size. It is usually about three feet in length and two feet high, with haunches considerably more elevated than the shoulders. From its upper jaw two tusks project downward out of the mouth, each about two inches long, curved backward, and serving to extract the roots which are used as food by the animal. The ears are long and narrow, and the tail very short. The fleece, consisting of strong, elastic, undulated hairs, varies in color with the season, the age of the animal, and perhaps the place which it inhabits. The general color is a deep iron-gray. The individual hairs are whitish near the root, and fawn-colored or blackish towards the tip. The musk is contained in an oval, hairy, projecting sac, found only in the male, situated between the umbilicus and the prepuce, from two or three inches long, and from one to two broad, opening by a small hairy orifice at its anterior part, and marked posteriorly by a groove or furrow which corresponds with the opening of the prepuce. It is lined internally by a smooth membrane, thrown into a number of irregular folds, forming incomplete partitions. In the vigorous adult animal, the sac sometimes contains six drachms of musk; but in the old, seldom more than two drachms, and none in the young.¹ The musk is secreted by the lining membrane, and in the living animal forms a consistent mass, which on the outside is compact, and marked with the folds of the membrane, but is less firm towards the centre, where there is sometimes a vacant space. As first secreted it is probably liquid, and a portion is occasionally forced out by the animal, to which it communicates its odor. The musk-deer inhabits the vast mountainous regions of Central Asia, extending from India to Siberia, and from the country of the Turcomans to China.

It is an active and timid animal, springing from rock to rock with surprising agility, and frequenting the snowy recesses and most inaccessible crags of the mountains. Concealing itself during the day, it chooses the night for roaming in search of food, and, though said to be abundant in its native regions, is taken with difficulty. It is hunted for its hide, as well as for the musk. The natives often take it by snaring. As soon as the animal is killed, the sac is cut off, dried, and sent into the market.² It has been calculated that about twenty thousand deer, male and female, are annually killed.

Musk varies in quality with the country inhabited by the animal. That procured from the mountains on the southern borders of Siberia, and brought into the market through Russia, is comparatively feeble. Chinese musk has been said to come from Tonquin, but appears really to be chiefly obtained in Yun-Nan, a province in the extreme south of China, whence it is sent 1400 miles to Shanghai, the export centre. A variety intermediate between these is procured in the Himalaya Mountains and Thibet and sent to Calcutta. This is sometimes enclosed in the membranous lining of the sac, without the hairy envelope, and in this condition is said to be quite equal if not superior to that surrounded by the skin, as in the former condition it dries readily in the sun, while in the latter the aid of artificial heat is deemed necessary, by which the musk may sometimes be injured. (F. Peake, *P. J.*, Feb. 1861.) A musk which is also said to pass from Thibet into China is *Cabardine* musk. (See *C. D.*, 1890.)

Two varieties are known in commerce, the *Chinese*, *Thibet* or *Tonquin* musk, and *Russian* or *Siberian* musk.³ Both come in sacs, convex and hairy on one side, flat and destitute of hair on the other. The hairs are brownish-yellow, grayish, or whitish, stiff and short, and arranged concentrically around the orifice of the sac. The Chinese, which is the more highly valued, is in bags of a rounder shape, covered with brownish-yellow or reddish-brown hairs, and containing at most a drachm and a half of large grained, dark, strong scented musk, of an ammoniacal odor. The Russian is in longer and larger bags, small-grained, of a light yellowish-brown color, and of a weaker and more fetid odor, with less odor of ammonia.

² Attention has been drawn by E. Bertherand to the excrement of the Algerian gazelle, *Antilope dorcas*, L., which possesses a powerful musk-like odor. It is said to contain about .7 per cent. of an acid resin having a musky odor. (*Proc. A. Ph. A.*, xxvi. 332.)

¹ According to Frederick Markham, as much as two ounces are sometimes obtained, and the average for a full-grown animal is an ounce; but, as many of the deer are killed young, the pods in the market do not contain more than half an ounce upon an average. He states that the musk of the younger animals is not so strong as that of the old, but is much pleasanter. (*P. J.*, xv. 472.)

³ *American Musk*.—Owing to the costliness of true musk, the sacs derived from *Fiber zibethicus*, the common musk-rat, have been used as a substitute. This product possesses many of the properties of musk, and, although the odor is not identical, it can often replace it in perfumery if used judiciously. If the fatty matter present has become rancid, it should be washed out by agitating the bruised sacs with a little ether and pouring off the ethereal solution, then allowing the musk to become dry by exposure to the air, and carefully preserving the product in sealed packages.

Properties.—Musk is in grains or lumps concreted together, soft and unctuous to the touch, and of a reddish-brown or ferruginous color resembling that of dried blood. Some hairs of the pod are generally mixed with it. It is officially described as “usually in irregular, crumbly, somewhat unctuous grains, dark reddish-brown, having a peculiar, penetrating, and persistent odor and a bitterish taste. About 10 to 12 percent. of Musk is soluble in alcohol, the solution being light brownish-yellow, and on the addition of water becoming slightly turbid; from 50 to 75 percent. is soluble in water, the solution being deep brown, faintly acid, and strongly odorous; moisture not more than 15 percent., and ash not more than 8 percent.” *U. S.* The odor is strong, penetrating and so diffusive that one part of musk communicates its odor to more than 3000 parts of inodorous powder. (Fée.) In some delicate individuals it produces headache and other disagreeable symptoms, and it has even caused convulsions. The taste is bitter, disagreeable, and somewhat acid. The color of the powder is reddish-brown. Musk is inflammable, burning with a white flame, and leaving a light spongy charcoal. Reduced to ashes, it leaves about 5 percent. of residue, containing potassium, calcium, magnesia, iron, carbonic, phosphoric, and sulphuric acids, chlorine, and traces of potassium ferrocyanide and ammonium sulphide. (W. Bernatzik.) It yields, upon analysis, a great number of proximate principles. Guibourt and Blondeau obtained water, ammonia, stearin, olein, cholesterin, an oily acid combined with ammonia, volatile oil, ammonium chloride, potassium and calcium chlorides, an unidentified acid combined with ammonia, potassium, and calcium, gelatin, albumin, fibrin, a highly carbonaceous matter soluble in water, a soluble calcareous salt and a combustible acid, calcium carbonate, and phosphate, with hair and sand. (*Ann. Ch. Phys.*, ix. 327.) Besides these constituents, Geiger and Reinman found a peculiar bitter resin, a peculiar substance in part combined with ammonia, and lactic acid both free and in combination. According to Guibourt and Blondeau, it contains 47 per cent. of volatile matter, thought by some to be chiefly ammonia, by others to be a compound of ammonia and volatile oil. Theimann obtained only from 10 to 15 per cent. But the quantity of volatile as well as of soluble matter varies exceedingly in different specimens. Thus, Theimann found from 80 to 90 per cent. of matter soluble in water, Buchner only 54.5 per cent., and other chemists intermediate proportions. The proportion soluble in alcohol, as ascertained by different experimenters, varies from 25 to 62 per cent. Ether is a good solvent. The aqueous infusion has a yellowish-brown color, a bitterish taste, a strong odor, and an acid reaction. The alcoholic tincture is transparent, and of a reddish-brown color, with the peculiar odor of musk. The action of potassium hydroxide upon musk is accompanied with the extrication

of ammonia and an increase of its peculiar odor. By the influence of heat and moisture long continued, ammonia is developed, which acts upon the fatty matter, producing a substance resembling adipocere, but, according to Guibourt, without diminishing the medicinal activity. The correctness of this opinion, however, is perhaps questionable, and it is advisable to preserve the musk as much as possible unaltered. When kept in glass bottles, in a situation neither moist nor very dry, it remains for a great length of time without material change. The odor of musk is very much diminished by mixing it with emulsion or syrup of bitter almond, or with cherry-laurel water. From the experiments of Wimmer, it appears that musk loses its odor when rubbed with golden sulphide of antimony, and reacquires it on the addition of a little solution of ammonia. (*Ph. Cb.*, 1843, 406.) Camphor rubbed up with musk is also said to destroy its odor. (See *Artificial Musk*, PART II.)

Adulterations.—The price of this medicine is so high, and its sources are so limited, as to offer strong temptations to adulteration, and little genuine unmixed musk is to be found in the market. The sophistication commences in China, and is completed in Europe and this country. A common practice in the East is to open the sac and to supply the place of the musk with an adulterated mixture. Sometimes the serotum of the animal is filled with this mixture, and not infrequently the sacs are made out of the skin. Dried blood, from its resemblance to musk, is one of the most common adulterations; but, besides this, sand, lead, iron filings, hair, animal membrane, tobacco, the dung of birds, wax, benzoin, storax, asphaltum, artificial musk, and other substances are introduced. These are mixed with a portion of musk, the powerful odor of which is diffused through the mass and renders the discovery of the fraud sometimes difficult. It is said that the Chinese sometimes mix the musk of Tonquin with that of Siberia. The bags containing the drug should have the characters before described as belonging to the natural sac, and should present no evidence of having been opened. The slit is sometimes carefully sewed up, sometimes glued together. The former condition may be discovered by close inspection, the latter by immersion in hot water. When the bag is made from any other portion of the skin, the difference may be detected, according to Neligan, by a microscope which magnifies 300 diameters. The genuine hairs exhibit innumerable cells, which are wanting in the spurious. (*Chem. Gaz.*, Feb. 1846, p. 79.) Musk which burns with difficulty, has a feeble odor and a color either pale or entirely black, feels gritty to the finger, is very moist so as to lose much weight in drying, or contains obvious impurities, should be rejected. Russian musk is said never to be adulterated before leaving Russia.¹ “Musk

¹ For an account of the effects of numerous reagents on musk, and other modes of identification,

should be free from earthy impurities, and should on incineration yield not more than 8 per cent. of ash." *Br.*

Uses.—Musk is stimulant and antispasmodic, in some way stimulating very decidedly the nervous centres when exhausted, without producing either in health or in disease very pronounced symptoms. It is a very valuable remedy in the treatment of nervous exhaustion coming on at or about the crisis of acute disease. When, in low cases of *typhus affections*, *subsultus tendinum*, *tremors*, *singultus*, and similar symptoms indicate the failure of nerve-power, its exhibition is often of great advantage. We have seen it apparently save life in the acme of *typhoid fever*, when the vital powers seemed to have almost succumbed, and when violent alterations of temperature or symptoms resembling those of coma vigil had manifested themselves. It was many years ago especially commended by Trousseau in the treatment of *adynamic pneumonia* of drunkards with severe cerebral symptoms. Under these circumstances it certainly appears to do great good. In very obstinate *hiccough* it is one of the most efficient of all of our remedies, and, according to G. B. Wood, it is very effective in those alarming *convulsions of infants* originating in spasm of the intestines. In the *laryngismus stridulus* or crowing disease of infants, Bouchut relied mainly on musk, having found it more efficacious than any of the narcotics. (*N. Y. M. J.*, Sept. 1868, p. 545.) According to our experience, musk rapidly loses its power of influencing the nerve centres, and for this reason, and on account of its costliness, its employment should always be delayed until severe nervous exhaustion becomes alarming. It may be given in pill, but is commonly given in emulsion or administered as an enema.

Dose, from five to fifteen grains (0.32 to 1.0 Gm.).

Off. Prep.—Tinctura Moschi, *U. S.*

MUCILAGINES.

MUCILAGES

(mū-cl-lāg'ĭ-nēs)

Mucillages, *Fr.*; Schleime, *G.*; Muclilagines, *It.*

Mucilage, in the ordinary acception of the term, and in the sense in which it is employed in the *U. S. Pharmacopœia*, is an aqueous solution of gum, or of substances closely allied to it. In the *British Pharmacopœia* the term is applied also to the semi-liquid, jelly-like substance resulting from the cooling of a hot solution of starch.

as well as of detecting adulterations, see a paper by W. Bernatzik, in *A. J. P.*, 1861, p. 427. There is a discrepancy between Bernatzik's statement of the solubilities of musk and that quoted in the text above. According to the latter, ether is a good solvent; according to the former, ether and chloroform possess scarcely any solvent power. Solubility, however, cannot be relied upon as a test.

MUCILAGO ACACIÆ. *U. S.*, *Br.*

MUCILAGE OF ACACIA

(mū-cl-lā'gō a-cā'cī-æ)

Mucilage of Gum Arabic; Muclilage de Gomme, *Fr. Cod.*; Muclilage arabique, *Fr.*; Mucllago Gummi Arabici, *P. G.*; Gummischleim, *G.*; Mucllagine di gomma arabica, *It.*; Mucllago de goma arabica, *Sp.*

* "Acacia, in small fragments, *three hundred and forty grammes* [or 11 ounces av., 435 grains]; Lime Water, *three hundred and thirty grammes* [or 11 ounces av., 280 grains]; Water, a *sufficient quantity*, to make *one thousand grammes* [or 35 ounces av., 120 grains]. Wash the Acacia with cold Water, and allow it to drain. Add the Lime Water to it, and enough Water to make the mixture weigh *one thousand grammes* [or 35 ounces av., 120 grains], agitate or stir it occasionally until the Acacia is dissolved, and strain. Keep the product in well-stoppered, completely filled bottles, in a cool place." *U. S.*

"Gum Acacia, in small pieces, *4 ounces* (Imperial) or 100 grammes; Distilled Water, a *sufficient quantity*. Rapidly rinse the Gum Acacia with a little Distilled Water; then dissolve it in *six fluid ounces* (Imp. meas.) or one hundred and fifty cubic centimetres of Distilled Water in a closed vessel and strain." *Br.*

The gum used for this purpose should be in small fragments or coarse powder, as it is more readily dissolved in this state than when finely pulverized. Straining is necessary to separate the foreign substances which are often mixed with gum arabic. This mucilage is semi-transparent, almost colorless if prepared from good gum, viscid, tenacious, of a feeble peculiar odor, and nearly tasteless. By straining a solution of gum through a layer of freshly precipitated alumina it can be almost entirely decolorized, particularly if the operation be repeated several times. By keeping, the mucilage becomes sour, in consequence of the spontaneous generation of acetic acid, and this happens even though it be enclosed in well-stoppered bottles; but, according to Guérin the solution of pure gum undergoes no change *in vacuo*. Heat in its preparation is said to favor the production of acid, and hence cold has been substituted for boiling water in the present formulas. The *U. S. P.* (8th Rev.) directs the addition of lime water in making this mucilage; this addition has proved advantageous by neutralizing the acidity generally found in acacia and it promotes stability. According to R. Rother (*A. J. P.*, xlv. 113), if glycerin be employed in the proportion of one to eight of the mass, and the mixture of water and glycerin be added to the gum in a bottle and solution secured by agitation at intervals over several hours, the resulting mucilage does not spoil; the presence of glycerin is objectionable, however, for many of the uses of mucilage of acacia. E. D. Oesch (*West. Drug.*, 1892, 38) adds about 6 per cent. of alcohol as a preservative. Keller preserves the mucilage by the addition of acetanilide (two

grains in the fluidounce). (*C. D.*, 1896, 378.) Archer & Co. have found (*A. J. P.*, xlv. 469) that if "Tolu water" be substituted for water the mucilage will keep for months. The Tolu water is made by rubbing two drachms of the tincture with magnesium carbonate and two pints of water, and filtering. Mucilage is employed chiefly in the making of pills, and in suspending insoluble substances in water. In prescribing it for mixtures, it should be recollected that it is a solution of definite strength, containing, according to the U. S. formula, half an ounce of the gum to each fluidounce of mucilage. The British mucilage is a little stronger. The adhesiveness of the mucilage is stated to be very much increased by the addition of one part of aluminum sulphate to one hundred and twenty-five parts of the mucilage.

MUCILAGO SASSAFRAS MEDULLÆ.

U. S.

MUCILAGE OF SASSAFRAS PITH

(mû-cj-lă'gō sās'sa-frās mē-dŭl'lē)

Mucilage de Moëlle de Sassafras, *Fr.*; Sassafrasmarkschleim, *G.*

* "Sassafras Pith, two grammes [or 31 grains]; Water, one hundred cubic centimeters [or 3 fluidounces, 183 minims]. Macerate the Sassafras Pith in the Water during three hours, and strain without expression. This preparation should be freshly made when wanted." *U. S.*

This mucilage may be prepared in a much shorter time, if the pith be broken into small fragments and the mixture often agitated. When a thicker mucilage is desired, J. W. England recommends beating the pith with sterilized water in a mortar until pasty, expressing through coarse muslin, returning the residue, and continuing the process until a thick mucilage is obtained. (*A. J. P.*, 1894, 350.) This will produce a cloudy mucilage, however, which is inferior to the preparation made without agitation. The use of sterilized water while not objectionable seems unnecessary unless the pith itself be sterilized. The mucilage is much used as an application to the eye in *conjunctivitis*. It may be taken as a drink *ad libitum* in inflammations of the mucous passages.

MUCILAGO TRAGACANTHÆ. U. S., *Br.*

MUCILAGE OF TRAGACANTH

(mû-cj-lă'gō trăg-a-căn'thæ)

Mucilage de Gomme Adragante, *Fr. Cod.*; Mucilage adragant, *Fr.*; Tragantenschleim, *G.*; Mucilagine di gomma adragante, *It.*

* "Tragacanth, six grammes [or 93 grains]; Glycerin, eighteen grammes [or 278 grains];

Water, a sufficient quantity, to make one hundred grammes [or 3 ounces av., 231 grains]. Mix the Glycerin with seventy-five cubic centimeters [or 2 fluidounces, 257 minims] of Water in a tared vessel, heat the mixture to boiling, add the Tragacanth, and macerate during twenty-four hours, stirring occasionally. Then add enough Water to make the mixture weigh one hundred grammes [or 3 ounces av., 231 grains], beat it until it has a uniform consistence, and strain it forcibly through muslin." *U. S.*

"Tragacanth, in powder, 60 grains (Imperial) or 5.5 grammes; Alcohol (90 per cent.), 2 fl. drachms (Imp. meas.) or 10 cubic centimetres; Distilled Water, a sufficient quantity. Mix the Tragacanth with the Alcohol in a bottle; add a sufficient quantity of Distilled Water to form ten fluid ounces (Imp. meas.) or four hundred cubic centimetres, and shake immediately." *Br.*

A part only of tragacanth is soluble in water. The remainder swells up and forms a soft tenacious mass, which may be mechanically mixed with water, but does not form a proper solution. Hence trituration is necessary to complete the incorporation of the ingredients. This mucilage is thick and very viscid, but not permanent, as the water separates from the insoluble portion of the tragacanth on standing. It is chiefly used in making pills and troches. The addition of glycerin renders it more serviceable as an excipient. From its great tenacity, it may be advantageously employed for the suspension of heavy insoluble substances, such as the metallic oxides, in water. When kept long, it is apt to undergo decomposition, and to become offensive, but it will keep well if enough phenol be added to impart its characteristic odor faintly. (*A. J. P.*, 1864.) Lyon (*P. J.*, 1901, 600) recommends the use of chloroform water as a preservative in making this mucilage; this is preferred in all cases if the mucilage is not to be used internally. The alcohol in the British process facilitates the quick production of the mucilage, and in addition acts as a preservative.

Off. Prep.—Lotio Hydrargyri Nigra, *Br.*; Trochisci Sodii Bicarbonatis, *U. S.*

MUCILAGO ULMI. U. S.

MUCILAGE OF ELM

(mû-cj-lă'gō ŭl'mī)

Mucilage of Slippery Elm Bark; Mucilage d'Ecorce d'Orme fauve, *Fr.*; Ulmenrindenschleim, *G.*

* "Elm, bruised, six grammes [or 93 grains]; Water, one hundred cubic centimeters [or 3 fluidounces, 183 minims]. Digest the Elm with the Water, on a water-bath, in a covered vessel, during one hour, then strain. This preparation should be freshly made when wanted." *U. S.*

This may be used *ad libitum* as a demulcent and nutritious drink in *catarrhal* and *nephritic*

diseases, and in inflammatory intestinal affections. It is much employed locally as a soothing application to boils and carbuncles, and as a demulcent in dermatitis, erysipelas, etc.

MYRISTICA. U. S., Br.

MYRISTICA [Nutmeg]

(mý-ris'tj-cə)

"The kernel of the ripe seed of *Myristica fragrans* Houttuyn (Fam. *Myristicaceæ*)." U. S. "The dried seed of *Myristica fragrans*, Houtt., divested of its testa." Br.

Muscade, Fr. Cod.; Nux Moschata, Nolz muscade, Fr.; Semen Myristice, P. G.; Muskatnuss, G.; Noce moscata, It.; Nuez moscada, Sp.

Myristica fragrans, Houttuyn, Nat. Hist. vol. ii., part iii., 333; B. & T. 218.¹ *M. moschata*, Thunberg; Willd., Sp. Plant. iv. 869. *M. officinalis*, Linn., Suppl. 265; Lindley, Flor. Med. 21.—The nutmeg tree is about thirty feet high, with numerous branches, and an aspect somewhat resembling that of the orange tree. The leaves stand alternately on short foot-stalks, are oblong-oval, pointed, entire, undulated, obliquely nerved, bright green and somewhat glossy on their upper surface, whitish beneath, and of an aromatic taste. The flowers are male and female upon different trees. The former are disposed in axillary, peduncled, solitary clusters; the latter are single, solitary, and axillary; both are minute and of a pale yellowish color. The fruit, which appears on the tree mingled with the flowers, is round or oval, of the size of a small peach, smooth, at first pale green, but yellow when ripe, and marked with a longitudinal furrow. The

¹ Various species of the genus *Myristica*, other than those spoken of in the text, yield commercial seeds or products:

Ucuhula nut is a round or oval seed of *Myristica surinamensis*. It is one-half to two-thirds of an inch in diameter, light brown, but usually covered by a blackish, thin, friable testa. Internally it resembles the nutmeg, but is distinguished by the presence of extraordinarily large and handsome albuminous crystalloids. These seeds are said to contain over 70 per cent. of a solid yellow fat, melting at 36° C. (See A. J. P., 1886; also A. Pharm., July, 1888.) The kernel of the fruit of the Brazilian *Myristica officinalis*, Mart. (*M. bicuhyba*, Schott), resembles the nutmeg in form and structure, but is covered with a black shell marked with broad furrows. It contains crystals like those above spoken of, but less splendid and regular, and apt to be in three forms. It yields a fat (*bicuhyba fat*, or *bicuhyba balsam*) very much like that of the ordinary nutmeg, but having a rather sour, sharp taste, melting at 47° C. It contains a peculiar fatty acid, *bicuhybastearic acid*. The *oboba fat* is the product of the fruit of *Myristica Oboba*. It is almost colorless, when fresh has a nutmeg-like odor, melts at 38° C., and contains *myristin*, *olein*, and *obobite*. The latter principle crystallizes in shiny, colorless crystals, melting at 132° C. The fruit of *Virola sebifera*, Aubl. (*s. Myristica sebifera*, Lam.), also yields a fatty substance which is known as *ocuba waa*. The so-called *California nutmeg* is not a nutmeg at all, but the seed of a coniferous tree, *Torreya californica*. It is oblong, with a smooth, brownish, thin testa, and affords a marbled cross-section. Its odor and taste are terebinthinate. Neither are the *Jamaica* or *calabash nutmeg*, from *Monodora Myristica*, the *New Holland* or *plume nutmeg*, from *Atherosperma moschata*, and the *olive nutmeg*, from *Agathophyllum aromaticum*, true nutmegs.

external covering, which is at first thick and fleshy and abounds in an austere, astringent juice, afterwards becomes dry and coriaceous, and, separating into two valves from the apex, discloses a scarlet reticulated membrane or arillus, commonly called *mace*, closely investing a thin, brown, shining shell, which contains the kernel or *nutmeg*. The nutmeg tree is a native of the Moluccas and other neighboring islands, and abounds especially in that small cluster distinguished by the name of Banda, whence the chief supplies of nutmegs were long derived. But numerous varieties of the plant are now cultivated in Sumatra, Java, Singapore, Penang, Ceylon, and other parts of the East Indies, and have been introduced into the Isles of France and Bourbon, Cayenne, and several of the West India islands. The larger part of the nutmegs of commerce is, however, said still to come from the Dutch Banda Islands. The Penang nutmegs are distinguished by not being limed. The tree is produced from the seed. It does not flower until the eighth or ninth year, after which it bears flowers and fruit together, without intermission, and is said to continue bearing for seventy or eighty years. Little trouble is requisite in its cultivation. A branch of the female tree is grafted into all the young plants when about two years old, so as to insure their early fruitfulness. In the Moluccas the tree yields three crops annually. The fruit is gathered by hand, and the outside covering rejected. The arillode, mace of commerce,² is then carefully separated, so as to break it as little as possible, is flattened, dried in the sun, and afterwards sprinkled with salt water, with the view of contributing to its preservation. The nuts are dried in the sun or by ovens, and exposed to smoke until the kernel rattles in the shell. They are then broken open, and the kernels, having been removed and steeped for a short time in a mixture of lime and water, in order to preserve them from the attacks of worms, are next cleaned, and packed in

² MACIS, U. S. 1890, *Mace*, occurs in narrow bands, 25 mm. or more long, somewhat branched and lobed above, united into broader bands below; brownish-orange; fatty when scratched or pressed; odor fishy, grant, taste warm and aromatic." U. S. 1890. The structure of mace is largely made up of uniform, small, angular, parenchymatous cells, interspersed with numerous brown oil-cells of larger size. The inner part of the tissue contains also thin brown vascular bundles. The cells of the epidermis on either side are colorless, thick-walled, longitudinally extended, and covered with a peculiar cuticle of broad, flat, ribbon-like cells, which cannot, however, be removed as a continuous film. The parenchymatous cells are loaded with small albuminous granules, but do not contain starch. Mace is inferior when it is brittle, less than usually divided, whitish or pale yellow, or with little taste and odor. The presence of starch granules or other microscopic particles different from those spoken of in powdered mace is proof of adulteration. Mace contains from 7 to 9 per cent. of a volatile oil, the greater portion of which consists of *pinene*, along with which is some *myristicin*, $C_{12}H_{14}O_2$. Wallach separated two odoriferous fixed oils; one yellow, soluble in ether, insoluble in boiling alcohol; the other red, soluble in alcohol and ether in every proportion. Flückiger finds that, instead of the fats just described, there is about 25 per cent. of resin. (*Pharmacographia*, 509.)

casks or chests for exportation. Lumsdaine has found them to keep better if rubbed over with dry lime than when prepared in the moist way. (See *Am. J. Sci.*, Nov. 1851.) Tschirch confirms the value of liming as a preservative against the attacks of insects. (*Ph. Rev.*, 1898, 196.) Nutmegs are brought to this country either directly from the East Indies or indirectly through England and Holland. They are also occasionally imported in small quantities from the West Indies.

The amount of unground nutmegs imported into the United States for the year ending June 30, 1903, was 2,365,624 lbs., valued at \$444,643, and for 1904, 1,498,600 lbs., valued at \$288,388.

Properties.—The nutmeg (*nux moschata*) is of a roundish or oval shape, obtuse at the extremities, marked with vermicular furrows, of a grayish color, hard, smooth to the touch, yielding readily to the knife or the grater, but not very pulverulent. When cut or broken it presents a yellowish surface, varied with reddish-brown, branching, irregular veins, which give to it a marbled appearance. These dark veins abound in oily matter, upon which the medicinal properties depend. The odor of nutmeg is delightfully fragrant, the taste warm, aromatic, and grateful. Its virtues are extracted by alcohol and ether. Myristica is officially described as "ovoid or ellipsoidal, about 25 Mm. long; externally light brown, reticulately furrowed, with a circular scar at the broad end; internally more or less mottled from the infolding of the light brown perisperm and tegumen with the yellowish-brown endosperm; easily cut, the cut surface having a waxy lustre; odor strongly aromatic; taste agreeably aromatic, warm, and slightly bitter." U. S. Clifford Richardson (*Bulletin U. S. Dep. Agriculture*, No. 13, 1887) gives as the average of three analyses of imported nutmegs: water, 5.56 per cent.; ash, 2.88; volatile oil, 3.23; fixed oil or fat, 34.22; starch, etc., 39.62; crude fibre, 9.21; albuminoids, 5.28: total 100.00. The volatile oil is obtained by distillation with water. (See *Oleum Myristicæ*.)

Under the names of *long*, *female*, or *wild nutmeg*, *Macassar nutmeg*, *Papua nutmeg*, *New Guinea nutmeg*, *horse nutmeg*, certain seeds have long been known in European commerce; they have finally become an important article of trade, nearly 77,000 kilos of them having been sold in Holland in the year 1894. These seeds have been variously ascribed to *M. fatua*, Houtt. (*M. tomentosa*, Thunb., *M. macrophylla*, Roxb.) and other species of the genus Myristica,¹ but by Bassermann and Warburg have in all their varieties been traced to the *M. argentea*, Warburg, of New Guinea, from which country they are often taken to Macassar to finally enter commerce as Macassar nutmegs. (*P. J.*, 1898, 97.) The numerous varie-

ties of these false nutmegs are readily reducible to two, which differ chiefly in size, the larger being commonly known as the Papua nuts, the smaller as the Macassar nuts. They are distinguished from the nutmeg by their greater length, their elliptical shape, their comparatively feeble odor and disagreeable taste, and by the absence of the dark brown veins.

Nutmegs have been punctured and boiled in order to extract their essential oil, and the orifice afterwards closed so carefully as not to be discoverable unless by breaking the kernel. The fraud may be detected by their lightness. They are also apt to be injured by worms, which, however, attack preferably the parts least impregnated with the volatile oil. The Dutch were formerly said to heat them in a stove in order to deprive them of the power of germinating and thus prevent the propagation of the tree. The largest nutmegs now command the highest prices. They should be rejected when very light in weight, with a feeble taste and odor, worm eaten, musty, or marked with black veins.

The *concrete* or *expressed oil of nutmeg* (*Oleum Myristicæ Expressum*, Br. 1885), often called *oil of mace*, or *nutmeg butter*, is obtained by bruising nutmegs, exposing them in a bag to steam, and then compressing them strongly between heated plates. A liquid oil flows out, which becomes solid when it cools. Nutmegs are said to yield from 10 to 12 per cent. of this oil, but Flückiger and Hanbury obtained as much as 28 per cent.¹ (See analyses of Richardson, quoted previously.) The best is imported from the East Indies in stone jars, or in rectangular blocks 10 inches long by 2½ inches wide, wrapped in palm leaves. It is solid, soft, unctuous to the touch, of a yellowish or orange-yellow color more or less mottled, with the odor and taste of nutmeg. It is composed, according to Schrader, of 52.09 per cent. of a soft oily substance, yellowish or brownish, soluble in cold alcohol and ether; 43.75 of a white, pulverulent, inodorous substance, insoluble in these liquids; and 4.16 of volatile oil. The pulverulent constituent, which received from Playfair the name of *myristin*, has a silky lustre, melts at 31° C. (88° F.), and yields on saponification glycerin and *myristic acid*, C₁₄H₂₈O₂. Myristin, C₂₁H₃₈(OC₁₄H₂₇O)₂, is a true fat, or *glyceryl myristate*. It is also found in spermaceti, in cocoanuts, and in the fixed oil of linseed and poppy oil. It may be obtained directly from nutmeg by

¹ The fresh juice of the *Myristica ghibosa* and *M. Kingii* are said to yield a kino-like extract containing over 30 per cent. of tannin. (*P. J.*, 65, 261.)

¹ A process for obtaining it by means of carbon disulphide has been proposed by Lepage of Gisors, in France, and has received the sanction of the Society of Pharmacy of Paris. It consists in treating the nutmeg, thoroughly comminuted, with three times its weight of the well-rectified liquid referred to, agitating the mixture frequently for 24 hours, expressing, repeating the process with two parts only of the menstruum, mixing the products of the two macerations, filtering in a covered vessel, and then distilling off the disulphide until the residue is entirely deprived of the solvent. (*J. P. C.*, 3e sér., xxxi. 28.) It would seem almost impossible to prevent the retention of a little of the solvent.

exhausting it by means of benzene, filtering the liquid, and allowing it to crystallize by spontaneous evaporation. To purify the product, it may be dissolved in a mixture of two parts of absolute alcohol and three of benzene with the aid of heat, then filtering the liquid while hot, and setting it aside. On cooling, it deposits the pure myristin in crystals. (*J. P. C.*, Juin, 1859, p. 471.) Analyzed by Koller, the expressed oil was found to contain, in 100 parts, 6 of a volatile oil analogous to the oil of mace, 70 of myristin, 20 of olein, 3 of resin, and 1 of salts, etc. (*A. Pharm.*, clxxiii. 280.) Wallach found in the volatile oil *pinene* and *dipentene* of the class of terpenes, and Semmler found *myristicol*, $C_{10}H_{16}O$, which is liquid, and *myristicin*, a solid ester of the composition $C_{12}H_{14}O_8$. An inferior kind of the oil is prepared in Holland, and sometimes found in commerce. It is in hard, shining, square cakes, lighter-colored than that from the East Indies, and with less odor and taste. It is supposed to be derived from nutmegs previously deprived of most of their volatile oil by distillation. An artificial preparation is sometimes sold for the genuine oil. It is made by mixing various fatty matters, such as suet, palm oil, spermaceti, wax, etc., adding some coloring substance, and giving flavor to the mixture by the volatile oil.

Uses.—Nutmeg unites to the medicinal properties of the ordinary aromatics considerable narcotic power. In the quantity of two or three drachms (7.7 or 11.6 Gm.), it has been known to produce stupor and delirium, and dangerous if not fatal consequences are said to have followed its free use in India. For cases, see *A. J. P.*, 1855; *B. M. J.*, Dec., 1889; also *L. L.*, Jan. 19, 1895. H. C. Wood found in experiments upon the lower animals that the oil of nutmeg is a powerful narcotic, with very much less sedative influence upon the heart than is possessed by most volatile oils. Injected into the circulation of the dog, it caused profound sleep, with slowing of the respiration, and, if the dose had been large enough, loss of reflex activity. Nutmeg is usually employed to cover the taste or correct the operation of other medicines, but more frequently as an agreeable addition to farinaceous articles of diet, and to various kinds of drink in cases of languid appetite and delicate stomach. It is usually given in substance, and is brought by grating to the state of a powder. *Mace* possesses properties essentially the same as those of nutmeg, and has caused alarming sensorial disturbances. (*G. C. Watson, Prov. M. S. J.*, Jan. 26, 1848.) It is, however, less used as a medicine. The dose of either is from five to twenty grains (0.32 to 1.3 Gm.). The volatile oil may be substituted, in the dose of from two to five minims (0.12 to 0.3 Cc.). The expressed oil is occasionally used as a gentle external stimulant, and is an ingredient in the *Emplastrum Picis* of the British Pharm. 1885.

Dose, five to twenty grains (0.32 to 1.3 Gm.).

MYRRHA. U. S., Br.

MYRRH

(myr'rhā)

"A gum-resin obtained from *Commiphora Myrrha* (Nees) Engler (Fam. *Burseraceæ*)." *U. S.* "A gum-resin obtained from the stem of *Balsamodendron Myrrha*, Nees, and probably other species." *Br.*

Somali Myrrh, Herabol Myrrh; Gummi Resina Myrrha; Myrrhe, *Fr. Cod.*; Myrrha, *P. G.*; Myrrhe, *G.*; Mirra, *It.*, *Sp.*; Murr, *Ar.*; Bowl, *Hindust.*

Though myrrh has been employed from the earliest times, it is still uncertain by what plant it is yielded. The *Amyris Kataf* of Forskhal, seen by that traveller in Arabia, was supposed by him to be the myrrh tree, but without sufficient proof. Afterwards Ehrenberg met on the frontiers of Arabia Felix with a plant from the bark of which he collected a gum-resin precisely similar to the myrrh of commerce. From the specimens of the plant taken by Ehrenberg to Germany, Nees von Esenbeck referred it to the genus *Balsamodendron* of Kunth, and named it *Balsamodendron Myrrha*. This genus was formed by Kunth from *Amyris*, and includes the *Amyris Kataf* of Forskhal, which may possibly also produce a variety of myrrh. The new genus differs from *Amyris* chiefly in having the stamens beneath instead of upon the ovary. It was not thought by De Candolle sufficiently distinct, but is now generally recognized under the name of *Commiphora*, first given it by Jacquin in 1797, and therefore preceding the name of Kunth by some 27 years. Berg found another species in Ehrenberg's collection, to which was attached a label by the discoverer, stating that he had collected myrrh from it, and proposed to call it *Balsamodendron ehrenbergianum*. (*A. J. P.*, 1873, 314.) Both Oliver and Trimen agree that this plant is not specifically distinct from *B. Opobalsamum*. The belief that myrrh is the product of *C. Myrrha* has been confirmed by the German traveller Hildebrand, who collected the plant in 1873, in the Adel Mountains, on the north Somali coast (*P. J.*, 3d ser., ix. 893). Deflers and Schweinfurth (*Ber. d. Pharm. Ges. zu Berlin*, 1893) are probably correct in believing that genuine myrrh is yielded by *Commiphora abyssinica* (Berg.), Engl., which is found in Southern Arabia, Eritrea, and Northern Abyssinia. *C. Schimperi* (Berg.), Engl., occurring in the Yemen, Abyssinia, and from Kern to Tigré, is likely also to yield some of the com-

mercial Arabian myrrh. *C. Myrrha* (Nees), Engl., does not apparently produce any myrrh, although Hildebrand states that a plant of the Somali region resembling *C. Myrrha*—but probably a distinct species, *C. Playfairii* (Hook. f.), Engl.,—yields naturally myrrh. On the other hand, the director of the Kew Gardens believes that myrrh is yielded by *C. Myrrha* and *C. simplicifolia*, while E. M. Holmes is of the opinion that Arabian myrrh is the product of *C. Myrrha*. It appears to be established that *C. Myrrha* produces myrrh, but it is probable that it is also yielded by other trees belonging to the genus *Commiphora*, which genus includes more than 60 species, natives of Arabia and Africa.

Commiphora Myrrha, Nees, Engler.—*Balsamodendron Myrrha*, Feé, *Cours d'Hist. Nat. Pharm.*, i. 641; Carson, *Illust. of Med. Bot.*, i. 28, pl. 20; B. & T. 60.—This is a small tree, with a stunted trunk, covered with a whitish-gray bark, and furnished with rough abortive branches terminating in spines. The leaves are ternate, consisting of obovate, blunt, smooth, obtusely denticulate leaflets, of which the two latter are much smaller than the one at the end. The fruit is oval-lanceolate, pointed, longitudinally furrowed, of a brown color, and surrounded at its base by the persistent calyx. The tree grows in Arabia Felix, in the neighborhood of Gison, in dwarfish thickets, interspersed among the *Acaciæ* and *Euphorbiæ*. The juice concretes spontaneously upon the bark.

Formerly the best myrrh was brought from the shores of the Red Sea by way of Egypt and the Levant, and hence received the name of *Turkey myrrh*, while the inferior qualities were imported from the East Indies, and commonly called *India myrrh*. These titles have ceased to be applicable, as myrrh of all qualities is now brought from the East Indies, whither it is carried from Arabia and the northeastern coast of Africa. Aden in the former region, and Berbera in the latter, would appear, from the statements of James Vaughan, to be the chief entrepôts of the trade. (*P. J.*, xii. 226.) Great quantities are collected on the African coast, near the mouth of the Red Sea, whence it is taken to Aden. (*Ibid.*, Oct. 1859, p. 217.) It is usually imported in chests containing between one and two hundred-weight. Sometimes the different qualities are brought separate, but oftener more or less mingled. Only the best kind should be selected for medicinal use.¹

¹ According to G. Schweinfurth, *Mecca Balsam* is yielded by *Commiphora Opobalsamum*, from which it is collected in the valleys near Mecca. It is said to be the myrrh of the Bible, the error of translation having been made on account of the similarity of the old Hebrew word "mar" with the modern Arabic word "morr", the name of the true myrrh. Four varieties of myrrh are recognized by writers on *Materia Medica*. They are: First, *Somali Myrrh*, which is described in the *Pharmacographia* as follows: "Myrrh consists of irregular roundish masses, varying in size from small grains up to pieces as large as a hen's egg, and occasionally much larger. They are of an opaque reddish-brown color, with a

Properties.—Myrrh is in small irregular fragments or tears, or in larger masses, composed apparently of agglutinated portions differing somewhat in their shade of color. The pieces are exceedingly irregular in shape and size, being sometimes not larger than a pea, and sometimes, though rarely, almost as large as the fist. They are often powdery upon the surface. When of good quality, myrrh is reddish yellow or reddish brown and translucent, of a strong, peculiar, somewhat fragrant odor, and a bitter, aromatic taste. It is brittle and pulverizable, presenting when broken a shining surface, which in the larger masses is very irregular, and sometimes exhibits opaque whitish or yellowish veins. In powder it is of a light-yellowish color. Under the teeth it is at first friable, but soon softens and becomes adhesive. It is inflammable, but does not burn vigorously, and is not fusible by heat. Its sp. gr. is stated as 1.36. The inferior kind, commonly called *India myrrh*, is in pieces much darker than those described, more opaque, less odorous, and often abounding with impurities. We have seen pieces of *India myrrh* enclosing large crystals of sodium chloride, as if the juice had fallen from the tree and concreted upon the ground where this mineral abounds. Pieces of *bdellium*, and other gummy or resinous substances of unknown origin, are often mixed with it. Among these is a product which may be called *false myrrh*. It is in irregular pieces, of a dirty reddish-brown color, a vitreous brownish-yellow fracture, semi-transparent, of a faint odor of myrrh, and a bitter balsamic taste. Myrrh is best purchased in mass, as in powder it is liable to adulterations not easily detected. "In roundish or irregular tears or masses, dusty, brownish-yellow or reddish-brown; fracture waxy, somewhat splintery,

dull, dusty surface. When broken they exhibit a rough or waxy fracture, having a moist and unctuous appearance, especially when pressed, and a rich brown hue. The fractured translucent surface often displays characteristic whitish marks, which the ancients compared to the semicircular mark at the base of the finger-nails. It has a peculiar fragrance and an aromatic, very bitter, and somewhat acrid taste." Second, *Arabian Myrrh* or *Fahdli*, described in the *Pharmacographia* as "occurring in irregular masses, seldom exceeding 1½ inches long, and having a somewhat gummy-looking exterior. The larger lumps seem formed by the cohesion of small, rounded, translucent, externally shining drops or tears. The fracture is like that of common myrrh, but less unctuous, and has not the whitish markings. The odor and taste are those of the ordinary drug." This myrrh is said to be collected on the hills about Shugraea and Sureea, east of Aden. Third, "*Mecca Myrrh*," or *Arabian Myrrh* of *Dymock*, who states that it is sold in India as true myrrh. This myrrh has a dull surface, a dark reddish-brown color, a more unctuous and waxy fracture, and has white marks like *Somali myrrh*, which it resembles in taste, but its odor is rather less fragrant. Fourth, *Yemen Myrrh*, which is said by Hanbury to contain a resin which differs from that of *Somali myrrh* and the *Arabian myrrh* or *Fahdli* in that its solution in petroleum spirit does not give a violet color on the addition of bromine. This myrrh is said to enter commerce chiefly from Makulla via Aden and Bombay. It occurs in large pieces 1 to 3 inches long, irregularly rounded and characterized by a dark reddish brown color with a similarly colored fracture free from white streaks. Odor and taste similar to *Somali myrrh*, but stronger and more rank.

translucent on the edges, sometimes marked with whitish veins; odor balsamic; taste aromatic, bitter and acrid. When triturated with water, Myrrh yields a brownish-yellow emulsion; with alcohol it yields a brownish-yellow tincture which acquires a purplish-red tint on the addition of nitric acid. It does not swell or dissolve in water." U. S. Geo. F. Merson (*P. J.*, Jan. 1900, 42) proposes as a test of the quality of myrrh that it should yield not more than 5 per cent. of ash, which should be almost entirely soluble in diluted hydrochloric acid, and that when exhausted with 90 per cent. alcohol and dried at 100° C. one gramme should not afford more than 0.6 Gm. of residue.

Myrrh is partially soluble in water, alcohol, and ether. Triturated with water it forms an opaque yellowish or whitish emulsion, which deposits the larger portion upon standing. Its alcoholic tincture is rendered opaque by the addition of water, but throws down no precipitate. According to Neumann, alcohol and water severally extract the whole of its odor and taste. By distillation a volatile oil rises, having the peculiar flavor of myrrh, and leaving the residue in the retort simply bitter. The gum-resin is soluble in solutions of the alkalis, and, when triturated with them in a crystalline state, forms a tenacious liquid. Hence potassium carbonate may be used to facilitate its suspension in water. Hirschsohn recommends as a reagent for myrrh, *trichloroacetal-chloroform*, which is obtained by conducting chlorine into seventy-five per cent. alcohol until turbidity ensues and two layers are formed; the lower of these is shaken with an equal volume of water and then with calcined magnesia and filtered. In one part by weight of the trichloroacetal thus obtained, four parts by weight of hydrated chloral are dissolved by heating. The syrupy reagent thus made, which fumes slightly in the air, gives a violet color with the smallest quantity of pure Herabol myrrh. Hirschsohn failed to get a similar reaction with any other resin, not even with Bisabol myrrh. (*Ph. Centralh.*, 1903, 809.) An analysis by Ruickoldt gave 2.183 per cent. of volatile oil, 44.760 of resin, 40.818 of gum or arabin, 1.475 of water, and 3.650 of calcium and magnesium carbonate, with some gypsum and ferric oxide. The volatile oil has been called *myrrhol* or *myrrhenol*, and, according to Ruickoldt, has the formula $C_{10}H_{14}O$. Koehler (*A. J. P.*, 1890, p. 346) confirms this formula, and states that this body, while isomeric with thymol and carvol, is distinct from them. He found 7 or 8 per cent. of essential oil, instead of 2.18 as previously given. Gladstone (*J. Chem. S.* [2], 2, 1) found that the oil had a sp. gr. of 1.0189 at 75° C., a boiling point of 266° C., and was lævo-rotatory. The resin, which he calls *myrrhin*, $C_{15}H_{22}O_{10}$, is neutral, but becomes acid when kept for a short time in fusion. In the latter state Ruickoldt proposes to call it *myr-*

rhic acid. (*A. Pharm.*, lxi. 1.) Koehler (*Schim. Rep.*) finds in the portion soluble in alcohol an indifferent soft resin, to which he gave the formula $C_{26}H_{34}O_8$, containing three replaceable OH groups, and two dibasic resin acids, of the formulas $C_{26}H_{32}O_{16}$ and $C_{26}H_{32}O_8$. An investigation of the essential oil of *Bisabol* myrrh from the interior of the Somali country was made by W. Tucholka. (*Schim. Rep.*, Oct. 1897, 36.) He obtained by distillation 7.8 per cent. of an oil of 0.8836 sp. gr., boiling at from 220° to 270° C. From this was separated, by means of the crystalline hydrochloride, a terpene boiling at from 259° to 260.2° C., which the author calls *bisabolene*, and an oxygenated portion to which he gives the rather strange formula $C_{26}H_{36}O$. According to Bley and Diesel, myrrh containing little volatile oil always has an acid reaction, which they ascribe to the oxidation of the oil. They also found *formic acid* in the specimen examined by them. The same investigators propose as a test of myrrh the production of a transparent dirty-yellow liquid with nitric acid, while false myrrh affords a bright-yellow solution in the same fluid, and bdellium is not dissolved, but becomes whitish and opaque. (*A. J. P.*, xviii. 228.) According to Righini, if powdered myrrh, rubbed for fifteen minutes with an equal weight of ammonium chloride, and fifteen times its weight of water gradually added, dissolves quickly and entirely, it may be considered pure. Chas. E. Escott (*A. J. P.*, 1887) extracted a sample of myrrh with petroleum benzin, and on spontaneous evaporation of the solvent obtained 18.75 per cent. of oily residue. The gum left after treatment with alcohol had a barely perceptible odor of myrrh and a slightly mucilaginous taste, was neutral to test paper, and, though of a pale color, gave with water a dark-brown solution. The insoluble portion amounted to 15 per cent., or 8.4 per cent. of the weight of the myrrh. The diluted solution acquired a purple color by ferric chloride, changed to reddish yellow by ammonia. Stronger solutions were precipitated by alcohol, not gelatinized by borax, and the precipitate with lead subacetate was not redissolved. The gum makes a good mucilage, and, when making tincture of myrrh, the residue insoluble in the alcoholic menstruum should be saved for that purpose.

Uses.—Myrrh is a stimulant tonic, with some tendency to the lungs, and perhaps to the uterus. It is also employed as a tonic in *dyspepsia*, and as an expectorant and emmenagogue in *debilitated states* of the system, in the absence of febrile excitement or acute inflammation. The diseases in which it is usually administered are *chronic catarrh*, *phthisis pulmonalis*, other *pectoral affections* in which the secretion of mucus is abundant but not easily expectorated, *chlorosis*, *amenorrhœa*, and the various affections connected with this state of the uterine function. It is generally given combined with *chalybeates* or

other tonics, and in *amenorrhæa* very frequently with aloes. It is used also as an application to *spongy gums*, the *aphthous sore mouth* of children, and various kinds of *unhealthy ulcers*.

A *plaster of myrrh* is made by rubbing together powdered myrrh, camphor, and balsam of Peru, of each an ounce and a half, then adding the mixture to 32 ounces of lead plaster previously melted, and stirring well until the plaster thickens on cooling. It is then to be formed into rolls. This plaster may be employed in all cases where a gentle and long-continued rubefacient effect is desired.

Myrrh may be given in the form of powder or pill, or suspended in water, as in the famous antiseptic mixture of Griffith, which is official under the name of *Mistura Ferri Composita*. The infusion is also sometimes given, and an aqueous extract has been recommended as milder than myrrh in substance. The tincture is used chiefly as a local application.

Dose, ten to thirty grains (0.65 to 2 Gm.).

NAPHTHALENUM. U. S.

NAPHTHALENE [Naphthalinum, Pharm. 1890,
Naphthalin, Naphthalin]

(năph-tă-lě'nŭm)

$C_{10}H_8 = 127.10$

"A hydrocarbon obtained from coal-tar, and purified by crystallization. It should be kept in well-stoppered, amber-colored bottles." U. S.

Naphthaline; Naphtaline, Naphthalène, Fr.; Naphthalinum, P. G.; Naphthalin, G.; Naftalina, It.

This may be obtained by subjecting coal tar to distillation, when it passes over in the middle oil and heavy oil; in the fractions of the latter it often constitutes the main constituent, causing it to become almost solid on cooling. It is frequently produced during the dry distillation of organic bodies. For a method of preparing it on a large scale for commercial purposes, see a paper by Vohl, in the *J. P. C.*, 1868, 399; from *Polytech. Journ.*; see also Lunge's *Coal-tar and Ammonia*, London, 1887. It is made very extensively and cheaply at present, the sublimed commercial product being nearly pure. It is a white, shining, crystalline substance, fusible at 80° C. (176° F.), and boiling at 218° C. (424.4° F.), but volatilizing with vapor of water. According to Kopp, its sp. gr. in the liquid state is 0.9774; according to Alluard, at 98.8° C. (210° F.), 0.9628.

Properties.—It is officially described as in "colorless, shining, transparent laminae, having a strong, characteristic odor resembling that of

coal-tar, and a burning, aromatic taste; slowly volatilized on exposure to air; by exposure to light acquiring a brownish color. Insoluble in water, but when boiled with it, the water acquires a faint odor and taste; soluble in 13 parts of alcohol at 25° C. (77° F.), and very soluble in boiling alcohol; also very soluble in ether, chloroform, carbon disulphide, and fixed or volatile oils. Naphthalene volatilizes slowly at ordinary temperatures, but rapidly when heated. It also volatilizes with the vapors of water or alcohol. At 80° C. (176° F.) it melts, and at 218° C. (424.4° F.) it boils. Its vapor is inflammable, burning with a luminous but smoky flame. When ignited, it is consumed, leaving no residue. Naphthalene is neutral to litmus paper moistened with alcohol. On shaking a small portion of Naphthalene with concentrated sulphuric acid, the acid should remain colorless, and should not acquire more than a pale reddish tint if the mixture be heated for five minutes on a water-bath (absence of impurities derived from coal-tar)." U. S.

Uses.—Naphthalene has acquired in recent years a new industrial utilization, in that it is the starting point in the manufacture of artificial indigo, which has already become an extensive industry. (See *Indigo*, PART II.) Naphthalene is possessed of antiseptic properties, and is poisonous to most fungi and probably to most insects. Under the name of "*tar camphor*," it has largely supplanted true camphor as a means of preventing the deposition by moths of eggs in woolen clothing, and of preventing the destruction by insects in natural history museums. In internal medicine it was some years ago brought forward by Dupasquier as an expectorant especially valuable in *chronic bronchitis* accompanied with a large amount of secretion. It has also been used with asserted excellent results as a tænicide, and as a vermifuge in cases of *seat worms*, when it should be given by injection, from fifteen grains to half a drachm in two to three ounces of olive oil. First employed by Rossbach of Jena, in *intestinal catarrh*, it has been largely used in all forms of *intestinal inflammation* and in *typhoid fever*. There seems to be no doubt that in some cases it acts very happily, but the reports concerning it vary, and the remedy is probably inferior to naphthol. Eighty grains are said to have been given in a day without deleterious effects, but J. A. Otte (*Chinese Med. Missionary Journ.*, xi. 1897) violently poisoned himself by eight grains of naphthalene. The symptoms were excessive vomiting and purging and great abdominal pain, followed by nephritis. Moreover, employees in gutta-percha works, where it is largely used, are said to be occasionally thrown into a peculiar condition of delirious intoxication. 77 grains caused in a man a cataract requiring extraction of the lens (*S. J.*, 1902.) Naphthalene has been used externally as an antiseptic dressing, and also in the treatment of various skin diseases. When given

internally, it should always be in the form of powder, and is best administered in capsules.

Dose, one to three grains (0.065 to 0.2 Gm.).

NUX VOMICA. U. S., Br.

NUX VOMICA

(nūx vōm'ī-cə)

"The dried, ripe seed of *Strychnos Nux-vomica* Linné (Fam. *Loganiaceæ*), yielding, when assayed by the process given below, not less than 1.25 percent. of strychnine." *U. S.*
 "The dried ripe seeds of *Strychnos Nux-vomica*, Linn." *Br.*

Semen Nucis Vomice; Poison Nut, Quaker Buttons, Dog Buttons; Noix vomique, *Fr.* *Cod.*; Semen Strychni, *P. G.*; Krähenaugen, Brechnuss, *G.*; Noce vomica, *It.*; Nuez vomica, *Sp.*

Strychnos Nux-vomica, L., *Sp. Pl.* (1753) 189; Willd., *Sp. Plant.* i. 1052; B. & T. 178. This tree is of a moderate size, with numerous strong branches, covered with a smooth, dark gray bark. The young branches are long, flexuous, smooth, and dark green, with opposite, roundish-oval, entire, smooth and shining leaves, having three or five ribs, and short footstalks. The flowers are small, white, funnel-shaped, and in terminal corymbs. The fruit is a round berry, about as large as an orange, with a smooth, yellow or orange-colored, hard, fragile rind, and many seeds in a juicy pulp. It has frequently been asserted that the pulp is innocuous, but Flüchiger and Hanbury, and also Dunstan and Short (*P. J.*, xv. 1), have demonstrated that it contains strychnine. Dunstan and Short have also proved that of the commercial varieties of nux vomica in percentage of contained strychnine Bombay seed stands first, then Cochin, and lastly Madras. (*P. J.*, 1883, 1053.)

The tree is a native of the East Indies, growing in Bengal, Malabar, on the Coromandel Coast, in Ceylon, in many islands of the Indian Archipelago, in Cochin-China, and in other neighboring countries. The wood and root are very bitter, and are employed in the East Indies for the cure of intermittents. The *radices colubrinæ* and *lignum colubrinum* of the older writers, long known in Europe as narcotic poisons, have been ascribed to this species of *Strychnos*, under the impression that they were identical with *Strychnos colubrina*, to which Linnæus refers them. They were ascertained by Pelletier and Caventou's researches to contain a large quantity of strychnine. The bark is said by O'Shaughnessy to answer exactly to the description given by authors of the *false Angustura*, and, like that, to contain a large quantity of brucine. The identity of the two barks was confirmed by Pereira by a comparison of specimens. (See *Cuspariæ Cortex*.)

Properties.—The seeds are about three-quarters of an inch in diameter, and two lines in

thickness, flat or slightly convex on one side, and concave on the other, with a slight ridge extending from the centre of one side to the edge. They are thickly covered with fine, silky, shining, ash-colored or yellowish-gray hairs, springing from, and indeed composed of, elongated cells of a thin fragile coating or testa, which closely invests the interior nucleus or kernel. This is very hard, horny, usually whitish and semi-transparent, sometimes dark-colored and opaque, and very difficult of pulverization. It is composed chiefly of a hard, horny albumen, which on section is seen to be formed of numerous small parenchymatous cells. In a fissure in the centre lies the embryo. It is about a third of an inch long, with a club-shaped radicle and two cordate, five- to seven-nerved cotyledons. *Nux vomica* is officially described as "orbicular, nearly flat, sometimes irregularly bent, 15 to 30 Mm. in diameter, 3 to 5 Mm. thick; externally grayish or greenish-gray, the surface covered with short, closely appressed, satiny hairs; rounded or somewhat acute at the margin, with a slight ridge extending from the centre of one side to the edge; internally whitish-gray, horny, very tough, the endosperm in two more or less regular concavo-convex halves, between which, at one end, lie the heart-shaped, palmately nerved cotyledons; inodorous; taste intensely and persistently bitter. Powder light gray, the epidermal cells modified to strongly lignified hairs; endosperm cells thick-walled, containing a fixed oil and aleurone grains, and giving a blue or violet color with potassium dichromate and sulphuric acid; in the tissues of adhering fruit pulp occur a few small, nearly spherical starch grains." *U. S.* The powder is yellowish gray, and has a faint sweetish odor. The seeds are destitute of odor, but have an acrid, very bitter taste, which is much stronger in the kernel than in the investing membrane. They impart their virtues to water, but more readily to diluted alcohol. For a method of distinguishing powdered nux vomica from powdered ignatia and other powders, see *Proc. A. Ph. A.*, 1897, 503.

The chemists Pelletier and Caventou discovered in nux vomica two alkaline principles, *strychnine* and *brucine*, united with a peculiar acid which they named *igasuric*. Its other constituents are a yellow coloring matter, a concrete oil, gum, starch, a small quantity of wax, and several earthy phosphates. Charles Bullock, in preparing the alcoholic extract of nux vomica with a moderate continuous heat, so as to dry it sufficiently to be pulverized, separated from 150 pounds of the seeds 5 pints of a liquid oil. (*A. J. P.*, 1874, 405.)¹ Shenstone (*J. Chem. S.*, xxxix. 453) has shown that the *igasurine* of Desnoix is a mixture of strychnine and brucine. A glucoside, *loganin*,

¹ F. Meyer (*In. Dis.*, St. Petersburg, 1875) investigated the fatty oil from nux vomica, and found it to consist of the glycerides of capric, caprylic, caproic, butyric, and palmitic acids.

has also been found in the nux vomica seeds, but it exists more largely in the surrounding pulp. Dunstan and Short, its discoverers (*P. J.* [3], xiv. 1025), gave to it the formula $C_{25}H_{34}O_{14}$.¹ Boorsma stated that he had discovered a new alkaloid in the leaves of *S. Nux vomica* (*Bull. de l'Inst. Bot. de Buitenzorg*) and he named it *strychnicine*; it is only slightly poisonous. (See also *P. J.*, 1902, 65.)

Strychnine ($C_{21}H_{22}N_2O_2$) was discovered by Pelletier and Caventou in 1818, in both the nux vomica and the bean of St. Ignatius, and received its name from the generic title of the plants (*Strychnos*) to which these two products belong. According to these chemists, it exists much more abundantly in the bean of St. Ignatius than in the nux vomica, the former yielding 1.2 per cent., the latter only 0.4 per cent., of strychnine, but Dragendorff obtained from nux vomica from 1.9 to 2.1 per cent. of mixed alkaloids, about half of which was strychnine. (*Jahresbericht*, 1874, 103.)² For valuable practical information about the yield of the alkaloids, extracts, etc., by E. L. Patch, see *Proc. A. Ph. A.*, 1891, 91; also *P. J.*, 1889, 341; *Proc. Michigan Pharm. Assoc.*, 1889; *Proc. Ohio Pharm. Assoc.*, 1889; *P. J.*, 1890, 493.

Brucine ($C_{23}H_{25}N_2O_4$) was discovered by Pelletier and Caventou, first in the bark called *false Angustura*, in combination with gallic acid, and subsequently, associated with strychnine in the form of isasurates, in the nux vomica and the bean of St. Ignatius. It is crystallizable from alcohol, the crystals then containing $4H_2O$. It is without odor, but of a permanent, harsh, very bitter taste; is soluble

in 850 parts of cold and in 500 of boiling water; very soluble in alcohol, whether hot or cold; it dissolves in 4 parts of chloroform, 440 parts of ether, 60 parts of benzene, and 120 parts of petroleum benzin. It is permanent in the air, but melts at a temperature a little above that of boiling water, and on cooling congeals into a mass resembling wax. The hydrated crystals melt at $115^\circ C.$ ($239^\circ F.$), and sublime at $204^\circ C.$ ($399.2^\circ F.$), while the anhydrous base melts at $178^\circ C.$ ($352.4^\circ F.$), changing color, and depositing carbon. (*P. J.*, 1868, 375.) It forms crystallizable salts with acids. Concentrated nitric acid produces with brucine or its salts an intense crimson color, which changes to yellow by heat, and upon the addition of stannous chloride becomes violet. A test for brucine, given by Stanislas Cotton, consists in adding to a warm solution of brucine (from 40° to $50^\circ C.$) in nitric acid, a concentrated solution of sodium thiosulphate (hyposulphite). The mixture first becomes violet, and then passes to green when the alkaline salt is in excess. (*J. P. C.*, Juillet, 1869, 18.) These effects serve to distinguish brucine from strychnine, and, if produced with the latter alkaloid, evince the presence of the former. According to Laroque and Thibierge, auric chloride produces, with solutions of the salts of brucine, precipitates at first milky, then coffee-colored, and finally chocolate-brown. (*Journ. de Chim. Méd.*, Oct. 1842.) Chlorine water produces with solution of brucine a rose color, due to the formation of *dichlor-brucine*. This is a reddish-brown, hygroscopic powder. (*A. Pharm.*, 1886, 934.) A *dinitro-brucine*, $C_{23}H_{25}(NO_2)_2N_2O_4$, has also been obtained by the action of nitrogen trioxide upon the brucine in alcoholic solution. Brucine appears to bear a definite relation to strychnine in chemical constitution, being a *dimethoxy-strychnine*. According to the analyses of Shenstone and Dragendorff, the bark of the nux vomica contains brucine, with a trace of strychnine, while in the leaves Hooper found only brucine. (*P. J.*, xxi.)

This alkaloid has been detected in the body three months after death, being present in all the solids and fluids, but especially in the liver and kidneys. (*B. M. S. J.*, July 10, 1873, p. 36.) Brucine may be procured from *false Angustura* bark, in a manner essentially the same as that in which strychnine is procured from nux vomica, with this difference, that the alcoholic extract obtained from the precipitate produced by lime or magnesia should be treated with oxalic acid, and subsequently with a mixture of rectified alcohol and ether, which takes up the coloring matter, leaving brucine oxalate. This is decomposed by magnesia, and the brucine is separated by alcohol, which by spontaneous evaporation yields it in the state of crystals. Prescott (*Organic Analysis*, 1887, p. 458) gives two methods for the separation of strychnine from brucine; first, by the use of

¹ Loganin is present in the pulp to the amount of 4 or 5 per cent., and is contained in small quantity also in the seeds. It was obtained by exhausting the pulp with a mixture of chloroform and alcohol (100 : 25). The exhaustion was effected in an apparatus for hot repercolation. The percolate, on cooling, deposited crystals, which when recrystallized a number of times from alcohol, and finally from absolute alcohol, were obtained pure. Loganin is easily soluble in water and alcohol, less soluble in ether, chloroform, and benzene. Its aqueous solution is not precipitated by any of the alkaloidal reagents. Its most characteristic reaction is found in its behavior with concentrated sulphuric acid. A very small quantity of loganin, when gently warmed with a few drops of concentrated sulphuric acid, yields a fine red color, which, on standing, develops into a deep purple. By boiling with dilute sulphuric acid, loganin is resolved into glucose (reducing Fehling's solution), and a body for which the name *loganetin* is proposed. This substance, like loganin, gives the characteristic reaction with sulphuric acid, but the purple color does not develop so rapidly. Loganetin is soluble in water and alcohol, less soluble in ether, carbon disulphide and chloroform. (*P. J.*, 1884, p. 1025.)

² Other species of *Strychnos* contain the poisonous alkaloids, and may some time become a commercial source of them. *Bidara laut* of the Indian bazar, believed to be obtained from *S. ligustrina*, has been analyzed by Russow, who found the wood to contain 2.26 per cent. and the bark 7.38 per cent. of brucine without strychnine. Henry G. Greenish found in the wood and bark respectively of *S. colubrina* 0.96 per cent. and 5.54 per cent. of mixed alkaloids; the same analyst obtained from *false Angustura* bark (*S. Nux vomica*), young bark 3.10 per cent., old bark 1.68. (*P. J.*, 3d ser., ix. 1014.) According to Bernelot-Moens, the dry seeds of the *S. tieute* contain 1.469 per cent. of strychnine, with a trace of brucine. (*A. J. P.*, 1866, p. 506.) From the seeds of *Strychnos Rheedii*, W. R. Dunstan obtained a yield of 0.06 per cent. of brucine and no strychnine. (*Imp. Inst. Rep.*, 1901-2.)

alcohol of 0.97 sp. gr., which easily dissolves brucine, but has very slight solvent power upon strychnine; second, by Dunstan and Short's method with potassium ferrocyanide. This method has been reported upon by Holst and Beckurts (*Ph. Centralh.*, N. F., 1887, p. 119), who find that if the hydrochloric acid solution containing mixed alkaloids is not too dilute, on the addition of potassium ferrocyanide the whole of the strychnine will be precipitated as ferrocyanide, while the brucine salt will remain in solution.

The separation of brucine from strychnine is most conveniently effected by exposing the mixed alkaloids to the action of diluted nitric acid, which destroys brucine very rapidly while having no appreciable action on strychnine; this method is used in the official assay process (see below).

Igasurine was said to be found in the mother waters from which strychnine and brucine have been precipitated by lime. Jörgensen believed that it was identical with brucine (see *A. J. P.*, June, 1872, p. 257), and W. A. Shenstone confirmed this view. (*A. J. P.*, Dec. 1881.) Recent investigations show, however, that its existence is very doubtful.

Igasuric acid has been regarded as erroneously named, and investigators have stated that it was malic acid and tannic acid, while G. Sander (*A. Pharm.*, 1897, 133) believes that the acid found in nux vomica, heretofore known as *igasuric acid*, is *caffeo-tannic acid*.

The official process for determining the amount of strychnine present in nux vomica is as follows:

Assay. U. S. (8th Rev.)—"Nux Vomica, in No. 60 powder, *twenty grammes*; Ammonia Water, Ether, Chloroform, Alcohol, Normal Sulphuric Acid V.S., Fiftieth-normal Potassium Hydroxide V.S., Nitric Acid (sp. gr. 1.40), Sodium Hydroxide Solution (1 in 10), Tenth-normal Sulphuric Acid V.S., Sulphuric Acid Solution (3 percent. H_2SO_4), Iodeosin T.S., each, *a sufficient quantity*. Introduce the Nux Vomica into a 250 Cc. Erlenmeyer flask and add to it 200 Cc. of a mixture of 137.5 Cc. of ether, 44 Cc. of chloroform, 13.5 Cc. of alcohol and 5 Cc. of ammonia water; insert the stopper securely and macerate with frequent shaking during one hour and allow it to stand in a cool place for twelve hours. Decant into a measuring cylinder 100 Cc. of the liquid (representing 10 Gm. of Nux Vomica), and pour this into a separator, preferably of a globular shape. Rinse the cylinder with a little chloroform, add this to the separator, and then add 15 Cc. of normal sulphuric acid V.S.; shake the mixture moderately during one minute, being careful to avoid emulsification; when the liquids have separated completely, draw off the acid liquid into a beaker. Repeat the shaking out with successive portions of 5 and 3 Cc. of normal sulphuric acid V.S.; collect the acid solutions and pour them into a separator. If a drop of the last acid solution

yields a precipitate with mercuric potassium iodide T.S., repeat the shaking out of the ether solution with 5 Cc. of normal sulphuric acid V.S. To the combined acid solutions in the separator, add a small piece of red litmus paper, 25 Cc. of chloroform and then sufficient ammonia water to render the liquid alkaline, and shake the separator thoroughly. When the liquids have separated draw off the chloroform into a flask of 100 Cc. capacity, and repeat the shaking out of the alkaline liquid with two successive portions of 15 Cc. each of chloroform, adding the latter to that already in the flask. Evaporate the combined chloroformic solutions in the flask until the alkaloidal residue is dry, then dissolve it in 15 Cc. of sulphuric acid (3 percent.) warming it on a water-bath. When the solution has cooled, add 3 Cc. of a cooled mixture of equal volumes of nitric acid (specific gravity 1.40) and distilled water, and after rotating the liquid a few times, set it aside for exactly ten minutes, shaking it gently three times during this interval. Transfer the resulting red liquid to a separator containing 25 Cc. of an aqueous solution of sodium hydroxide (1 in 10) and wash the flask three times with very small amounts of distilled water, and add the washings to the separator. If the liquid is not turbid add 2 Cc. more of the solution of sodium hydroxide. Now add 20 Cc. of chloroform to the separator, and shake it well by a rotating motion for a few minutes, allow the liquids to separate, and draw off the chloroform through a small filter wetted with chloroform, into a flask. Repeat this twice, using 10 Cc. of chloroform each time, and draw off both portions into the flask, using the same filter. Finally, wash the filter and funnel with 5 Cc. of chloroform, and then evaporate all the chloroform by means of a water-bath very carefully, to avoid decrepitation. To the alkaloidal residue add 6 Cc. of tenth-normal sulphuric acid V.S., 5 drops of iodeosin T.S., about 80 Cc. of distilled water, and 20 Cc. of ether. When all the alkaloid is dissolved, titrate the excess of acid with fiftieth-normal potassium hydroxide V.S. until the aqueous liquid just turns pink. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract this number from 6 (the 6 Cc. of tenth-normal sulphuric acid V.S. taken), multiply the remainder by 0.0332, and this product by 10, which will give the percentage of strychnine in the Nux Vomica." U. S.

As a test for nux vomica, Vielgruth proposes to treat a few grains of the suspected powder with proof spirit, evaporate the tincture to dryness at a heat not exceeding 96°F ., then add a drop or two of diluted sulphuric acid, and again raise to the heat mentioned. If nux vomica be present, a beautiful carmine-red color will be produced, which will disappear in ten or fifteen minutes after cooling, and reappear, but less brightly, on the reapplication

of the heat. Schweissinger recommended the direct determination of the alkaloids in nux vomica by titration with hydrochloric acid as the best way of ascertaining the strength of pharmaceutical preparations. (*A. Pharm.*, 1885, 579.) Keller's method of estimating the alkaloids in nux vomica (see *Proc. A. Ph. A.*, 1895, 1024) is commended by Sander. (*A. Pharm.*, 1897, 133; see also *A. J. P.*, 1896, 189.)

BRUCINE.—On account of the difficulty of separating strychnine from brucine, it has been found by physiologists difficult to determine the exact action upon the human organism of the pure alkaloid. It would seem, however, from the studies of Reichert, made upon carefully tested brucine, that its physiological action is similar to that of strychnine, except that it is much less rapidly absorbed than is strychnine, is from forty to fifty times less powerful as a convulsant, is more poisonous to the sensory nerves, and is more uncertain in its effects upon bodily temperature. When brucine is brought in contact with the nerves of the frog it produces a rapid paralysis of the sensory fibres. Mays found that a five or ten per cent. solution of chemically pure brucine applied to the mouth of man causes rapid loss of sensibility, and asserts that a twenty per cent. solution is capable of exerting a decided local anæsthetic influence when placed upon the skin. He has found it very advantageous for the relief of the itching of *chronic pruritus*. Zeiss and Burnett find that a five per cent. solution gives a great relief as a local application in inflammations about the external ear, Burnett affirming that his results have been far more satisfactory than those which he has obtained with cocaine.

Uses.—The medicinal and toxic properties of nux vomica are those of its alkaloid. (See *Strychnina*.) The belief held by some physicians that it acts more favorably as a bitter upon the stomach has only this much of justification,—namely, that it is more slowly absorbed, and therefore acts locally somewhat more persistently.

Dose, one to four grains (0.065 to 0.26 Gm.).

Off. Prep.—*Extractum Nucis Vomice*, *U. S.*, *Br.* (from liquid extract); *Fluidextractum Nucis Vomice*, *U. S.* (*Br.*); *Tinctura Nucis Vomice*, *U. S.* (from extract), *Br.* (from liquid extract).

OLEA

OILS

(574-8)

These are liquid or solid substances, unctuous to the touch and characterized by inflammability and the property of leaving a greasy stain upon paper. They are divided into two classes, the *fixed* and the *volatile*, because distinguished, as their names imply, most readily by their different behavior on the application of heat.

OLEA FIXA. Fixed Oils.

Fats, Fatty Oils; Huiles Graisses, Huiles fixes, *Fr.*; Fette, Fette Oele, *G.*; Ollos, *It.*; Aceites, *Sp.*

These are sometimes termed *fatty oils*, because they constitute in part the vegetable and animal fats. The distinction between liquid and solid fats is for the most part a physical one only, as they contain the same chemical compounds, although in relatively different proportions. The fatty oils, though existing in greater or less proportion in various parts of plants, are furnished for use exclusively by the fruit, and, as a rule, are most abundant in the dicotyledonous seeds. They are obtained either by submitting the bruised seeds to pressure in hempen bags, or by boiling them in water, and skimming off the oil as it rises to the surface. When pressure is employed, it is customary to prepare the seeds for the press by exposing them to a moderate heat, so as to render the oil more liquid and thus enable it to flow out more readily. Another mode of extracting certain oils is by means of liquids having the power of dissolving them, and this method is now largely used in practice, carbon disulphide, carbon tetrachloride, and petroleum benzin being used. For the details of the process, see *A. J. P.*, Nov. 1868, 549. Fixed oils may be clarified by subsidence, filtration through animal charcoal or porous solids, precipitation with tannin, lead acetate, plaster of Paris, albumin, gelatin, or other agents; cellulose and asbestos filters are often used, and on the large scale, for separating mechanical impurities, centrifugal machines like those employed for milk. Fixed oils containing stearin or palmitin are likely to deposit these fats in cold weather, leaving the olein in a liquid condition. The olein may be separated by filtration in the cold.

CLASSIFICATION.

The following scheme of classification of the fixed oils, both liquid and solid (Allen, *Com. Org. Anal.*, 3d ed., vol. ii. part 1. pp. 88 to 102), gives a general view of their essential characters, points of difference, etc.

I. Olive Oil Group. Vegetable Non-drying Oils.—The oils of this group solidify on treatment with nitrous acid or mercuric nitrate, but do not lose their power of producing a greasy stain on paper, however long they may be exposed to the air. Their density varies from 0.914 to about 0.920, and hence is less than that of Groups III, IV, and V. Their fluidity is notably less than that of the drying oils.

This group includes almond oil (from *Amygdalus communis*), peach oil (from kernels of *Prunus Persica*), apricot oil (from kernels of *Prunus armeniaca*), oil of ben (from *Moringa oleifera*), earth nut oil (from *Arachis hypogaea*), and olive oil (from *Olea europaea*).

II. Rape Oil Group.—The oils of this group are all derived from the *Crucifera*. They

are non-drying but less distinctly so than the oils of Group I. They show higher saponification values, higher iodine absorption and less solid elaidins than Group I.

This group includes Colza oil and rape seed oil (from *Brassica campestris*, *B. napus* and other species); oil of black mustard (from seeds of *Brassica nigra*); oil of white mustard (from seeds of *Sinapis alba*).

III. Cotton Seed Oil Group.—The oils of this group occupy a position intermediate between the vegetable non-drying and the true drying oils (Groups I and IV). In density they somewhat exceed the oils of Group I, but are lighter than those of Groups IV and V. They form more or less elaidin on treatment with nitrous acid or mercuric nitrate, but do not become wholly solidified. On the other hand, they undergo more or less drying on exposure to the air, but not so markedly as the oils of Group IV.

This group includes beech nut oil (from *Fagus sylvatica*), cotton seed oil (from *Gossypium barbadense* and other species), hazel nut oil (from *Corylus avellana*, see *Proc. A. Ph. A.*, 1893), sesame or teal oil (from *Sesamum orientale*), and sunflower oil (from *Helianthus annuus*; *H. perennis*), camelina oil (from *Myagrum sativum*), and cress seed oil (from *Lepidium sativum*).

IV. Linseed Oil Group. Vegetable Drying Oils.—These oils are not solidified by treatment with nitrous acid or mercuric nitrate, but become gradually converted into solid masses or varnishes, by exposure to the air. In density the oils of this group vary from about 0.923 to 0.937, and hence are distinctly heavier than the non-drying oils and than most of the oils of Group III. On the other hand, they are lighter than the oils of Group V. The fluidity of the drying oils is also much higher than that of the non-drying oils.

This group includes niger seed oil (from *Guizotia oleifera*), hemp seed oil (from *Cannabis sativa*), linseed oil (from *Linum usitatissimum*; *L. perenne*), poppy seed oil (from *Papaver somniferum*), Scotch fir seed oil (from *Pinus sylvestris*), tobacco seed oil (from *Nicotiana Tabacum*), walnut oil (from *Juglans regia*), and weld seed oil (from *Reseda Luteola*).

V. Castor Oil Group.—The oils of this group are distinguished from those of Groups I, II, III, and IV, by their very high density and viscosity (i.e., deficient fluidity). They are also remarkable for their ready solubility in alcohol, and their marked purgative properties. In their drying characters and behavior with the elaidin test they resemble the oils of the cotton seed oil group. Both castor and croton oil are miscible in all proportions with glacial acetic acid.

This group includes castor oil (from *Ricinus communis*), croton oil (from *Croton Tiglium*), Japanese or Chinese wood oil (from seeds of *Aleurites cordata* or *Elæococca vernicia*), boiled

linseed oil, blown oils (made by oxidation of rape seed, cotton seed, linseed, lard, and other oils).

VI. Palm Oil Group. Solid Vegetable Fats. This group includes solid fats not containing notable quantities of glycerides of lower fatty acids. The densities for the melted fats at 98° and 99° C. are compared with the density of water at 15.5° C., taken as 1.000, and vary from 0.920 to 0.995.

This group includes palm oil (from fruit of *Elæis guineensis*), cacao butter (from nuts of *Theobroma Cacao*), nutmeg butter (from nuts of *Myristica fragrans*), and shea butter (from seeds of *Bassia Parkii*).

VII. Coconut Oil Group. Solid Vegetable Fats.—This group includes solid fats containing notable quantities of glycerides of lower fatty acids,—that is, of acids distilling with more or less facility in a current of steam at 100° C. The group includes coconut oil (from the nuts of *Cocos nucifera*), palm nut oil (from the kernels of the nuts from *Elæis guineensis*), laurel oil (from fruit of *Laurus nobilis*), Japan wax (berries of *Rhus succedanea*), myrtle wax (berries of *Myrica cerifera*). For a description with constants of some of the rarer fixed oils belonging to the vegetable group see papers by J. A. Wijs, *Ph. Zeit.*, 1903, 563; by Pancoast and Graham, *A. J. P.*, 1904, 70; and by Lewkowitsch, *P. J.*, 1904, 492.

VIII. Lard Oil Group. Animal Oleins.—This group includes those oils fluid at ordinary temperatures which are obtained from terrestrial animals. They resemble the whale or fish oils in their reaction with chlorine, but are not turned red or brown by boiling with caustic soda. On exposure to air and on treatment with nitrous acid or mercuric nitrate, they behave like the non-drying vegetable oils (Group I).

This group includes bone oil, lard oil, tallow oil, and neat's-foot oil. For a paper by P. L. Simmonds on various animal oils see *Bull. Pharm.*, 1893, 297, 344.

IX. Tallow Oil Group. Solid Animal Fats. This group comprises oils that are solid or semi-solid at ordinary temperatures. Their melting points vary somewhat, and are capable of permanent alteration. The group includes bone fat, butter fat, butterine and oleomargarine, hog's lard, horse fat, beef tallow and mutton tallow, and wool-fat (suint).

X. Whale Oil Group. Marine Animal Oils.—This group comprises the various fluid oils obtained from fish and cetaceous mammals. They are distinguished as a class by their offensive fishy odor, by the brown color they assume when subjected to the action of chlorine, and by the reddish color which is produced on boiling them with a solution of caustic alkali. With sulphuric acid they give colorations varying from light red to purple or brown. The fish oils do not dry up on exposure to air, and mostly yield but little elaidin on treatment with nitrous acid. The term "train oil" includes whale, seal, shark, cod,

and all similar oils. Cod oil (from *Gadus morrhua* and allied species), cod liver oil (from the same), menhaden oil (from *Alosa menhaden*), porpoise oil (from *Delphinus phocaena* and allied species), seal oil (from *Phoca* of various species), shark oil (from *Squalus maximus* and allied species), and whale oil (from *Balaena mystecetus* and allied species), are all members of this group.

XI. Sperm Oil Group. Liquid Waxes.—The members of this group differ from all the fatty oils of previous classes in not being glycerides, consisting essentially of esters of monatomic alcohols of the ethylic series, in which respect they resemble the true waxes, but are fluid at ordinary temperatures. They are less dense than glycerides, they do not dry or thicken notably on exposure to air, but they yield solid elaidins on treatment with nitrous acid. The group includes sperm oil (from cranial cavities of *Physeter macrocephalus*), doegling or bottle-nose oil, and dolphin oil.

XII. Spermaceti Group. Waxes proper. Spermaceti and the various waxes differ from the true fixed oils and fats in not forming glycerin when saponified, yielding instead certain of the higher monatomic alcohols, the identity of which varies with the nature of the wax. These alcohols are insoluble in water, and dissolve to but a limited extent in alcohol, but they are soluble in ether, chloroform, carbon disulphide, benzene, and petroleum benzin, and are apt to be mistaken for added paraffin wax when the substance is saponified and the soap extracted with a solvent.

This group includes beeswax (from honeycomb of various species of bees), Carnauba or Brazil wax (from the leaf-coverings of *Copernicus cerifera*), Chinese wax or Pela wax (produced by a species of *Coccus* which punctures the branches of certain trees), myrtle wax (from berries of *Myrica cerifera*), Ocuba wax (from *Myrica Ocuba*), palm wax (from bark of *Ceroxylon andicola*, of the Cordilleras), and spermaceti (deposited from the oil found in the cranial cavities of the sperm whale, *Physeter macrocephalus*).

When oils are decomposed by heat they emit vapors of *acrolein*, a highly volatile liquid resulting from the decomposition of glycerin, upon which the fumes of oils mainly depend for their irritating effects on the eyes and nostrils. Exposed to a red heat, in closed vessels, they yield, among other products of the destructive distillation, a large quantity of combustible and illuminating gases, among which ethylene and acetylene are readily recognized. Heated in the open air, they take fire, burning with a bright flame, and producing water and carbon dioxide. When kept in air tight vessels, they remain unchanged for a great length of time, but exposed to the atmosphere they attract oxygen and undergo change.¹ Some, in drying, lose their unctuous

character, and are converted into a transparent, yellowish, flexible solid. These are called *dry-ing oils*. Others, especially such as contain mucilaginous impurities, become rancid, acquiring a sharp taste and an unpleasant odor. This change is owing to the formation of an acid, from which the oil may be freed by boiling it for a short time with magnesium hydroxide and water.² The fixed oils are insoluble in water, but are miscible with that fluid by means of mucilage, forming mixtures which are called emulsions. They are in general very sparingly soluble in alcohol, but readily dissolved by ether, which serves to separate them from other vegetable proximate principles. By the aid of heat they can dissolve sulphur and phosphorus. The stronger acids decompose them, giving rise, among other products, to oleic, palmitic, and stearic acids. Boiled with diluted nitric acid, some of them give rise to malic and oxalic acids, besides other substances usually resulting from the action of this acid upon vegetable matter. Several acids are dissolved by them without producing any sensible change. They are decomposed by salifiable bases, which set free glycerin and oleic, stearic, or other fatty acids, which acids unite with the base employed. The compounds which these acids form with potassium and sodium hydroxide are called soaps. (See *Sapo* and *Emplastrum Plumbi*.) By the addition of one part of potassium or sodium carbonate, 160 parts of oil may be brought with distilled water into the form of an emulsion. The potassium and sodium soaps and the alkaline sulphides have a similar effect, but not

bon dioxide and introduced by him under the name of "effervescent oils" (see *Proc. A. Ph. A.*, 1900, 494). Under the influence of carbon dioxide, compounds which are easily split with the fatty acids are produced, which, particularly in the case of cod liver oil, permit the more complete absorption of the oil than is the case with oil not treated with carbon dioxide. The latter, moreover, acts as a preservative of the oils and renders them more palatable, destroying the unpleasant taste of cod-liver oil, and to a certain extent also that of added medicaments very materially. The absorptibility of carbon dioxide is, however, not the same in all oils. Cod liver oil is capable of absorbing the largest quantity, castor oil the smallest, while olive oil stands intermediate. (*Ph. Centralh.*, 1901, 485.)

² Cloes has made investigations in relation to the influence of light in promoting oxidation, and obtained some curious results. The general influence of light is very great, as oils undergo comparatively little change in the dark for a long time; though in relation to some of them the change is at length as great as under the light. Thus, while the oil of poppies had in 30 days increased about 5 per cent. in weight under colorless light, and had gained only a 5000th in the dark, yet at the end of 150 days the weight in the former condition was rather lessened than augmented, and in the latter, or in the dark, had increased 6.4 per cent. The effect of the different colored rays is also very different. The change is at first most rapid under the white light, less so under the blue, and much less under the red, yellow, and green, being least of all with the green; but with the advance of time the blue overtakes and even passes the white and at the end of three or four months all are about equal in effect. Heat also accelerates the concretion of the oils, by favoring their oxidation; and the same effect is produced by introducing into the unchanged oil a little which has already been altered by exposure to the air. The oxidation of an oil may be very greatly hastened in this way without the aid of heat. (*J. P. C.*, 4e sér., II. 345, 1865.)

¹ *Effervescent Oils*.—K. Dieterich recommends oils and fats which have been super-saturated with car-

the bicarbonates. The fixed oils also serve as good vehicles for various metallic bases and subsalts, which form soaps to a certain extent soluble in the oil, and thus become less irritant to the tissues. Oils thus impregnated may, like the pure oils, be brought to the state of emulsion with water, for convenient administration, by the addition of a small proportion of potassium carbonate. The fixed oils dissolve many of the alkaloids, the volatile oils, resin, and other proximate principles of plants. The alkaloids are more readily dissolved in them by being first combined with oleic acid, the oleates being more soluble than the alkaloids themselves. (Attfeld, *P. J.*, March, 1863, p. 308.) According to Buignet, they are, with very few exceptions, indifferent to polarized light; of all those used in medicine, the only exceptions being the liver oils of the ray and dog fish, which have a very feeble lævo-rotatory power, and castor oil, which is decidedly dextrogyrate. (*J. P. C.*, Oct. 1861, p. 264.)

It is very likely that, with the exception of castor oil, whose rotatory power is due to the asymmetric carbon atom of the ricinoleic acid, the rotatory power is not due to the glycerides themselves but to small proportions of optically active substances such as cholesterol. (Lewkowitsch, *Chem. Analysis of Oils, Fats and Waxes*, p. 121.)

The fixed oils, whether animal or vegetable, in their natural state consist in most cases of at least two or three distinct oleaginous ingredients, one liquid at ordinary temperatures, and the other two concrete. The liquid is a distinct proximate principle, called *olein*; the concrete principles consist of *stearin* and *palmitin*, the former being found most largely in animal and the latter in vegetable oils or fats, and the two in most cases existing together in the same oil. As the most frequent of these proximate constituents of the fixed oils, and existing in many different oleaginous substances, olein, palmitin, and stearin merit a special notice. Preliminarily to their individual consideration, it will be proper to refer to their nature and composition generally.

These three substances, *olein*, *palmitin*, and *stearin*, together with *butyrin*, *caprin*, and other minor fat principles, are *glycerides*; that is, esters or salts of the triatomic alcohol glycerol, $C_3H_5(OH)_3$, and of the several fatty acids, oleic, palmitic, stearic, etc., all of which are monobasic acids. The three mentioned glycerides have the following composition:

When these substances, or oils composed prin-

cipally of them, are treated with alkali with the aid of heat, the following decomposition takes place:

that is, olein is decomposed by sodium hydroxide into *glyceryl hydroxide*, or *glycerol*, and *sodium oleate*, or a sodium soap.

The waxes differ from the fats proper in being esters of the higher monatomic alcohols, like *cetyl alcohol*, $C_{26}H_{53}OH$, and *myricyl alcohol*, $C_{30}H_{61}OH$, instead of being glycerides. The fatty acids present are partly palmitic and stearic, but more largely still higher ones, like *cerotic acid*, $C_{27}H_{54}O_2$.

Olein. Elain. Liquid Principle of Oils.—It is extremely difficult to obtain olein pure. Being in most oils associated with the solids stearin and palmitin, it must be separated by pressure and other mechanical means, which separation is not always perfectly effected. As ordinarily procured, therefore, olein contains more or less of palmitin or stearin, or both. In this somewhat impure state it is obtained either by the agency of alcohol or by expression. When one of the oils, olive oil, for example, is dissolved in boiling alcohol, the solution, on cooling, deposits the concrete principles, still retaining the olein, which it yields upon evaporation. The other method consists in compressing one of the solid fats, or one of the liquid oils rendered concrete by cold, between folds of bibulous paper, which absorb the olein, and give it up afterwards by compression under water. Olein is a liquid of oily consistence, congealing at $-6^\circ \text{ C. (21.2}^\circ \text{ F.)}$, colorless when pure, with little odor and a sweetish taste, insoluble in water, soluble in boiling alcohol and ether. Its formula, as already stated, is $C_3H_5(OC_{18}H_{33}O)_3$, being an oleate of the triad radical *glyceryl*, C_3H_5 . By reaction with nitric acid, or, more exactly stated, under the influence of nitrous acid fumes, olein is converted into a deep yellow, butyraceous mass. If this be treated with hot alcohol, a deep orange-red oil is dissolved, and a peculiar fatty matter remains, called *elaidin*. This is white, crystalline, fusible at $34^\circ \text{ C. (93.2}^\circ \text{ F.)}$, insoluble in water, readily soluble in ether, and appears to be isomeric with olein. It is resolved by saponification with the alkalies into *elaidic acid* and glycerin.

Palmitin.—Palmitic acid occurs in the more liquid fats, such as palm oil and cocoa-nut oil, as well as in butter and human fat, as glyceride, while in spermaceti and some forms of wax it is combined with monatomic alcohol radicals. Palmitin is the *palmitic acid glyceride*, or *glyceryl tripalmitate*. It is best obtained from palm oil.

Stearin.—This exists abundantly in tallow and other animal fats. It may be obtained by treating the concrete matter of lard, free from olein, by cold ether so long as anything is dissolved. The palmitin is thus taken up, and stearin remains. A better method is to dissolve suet in heated oil of turpentine, allow the solution to cool, submit the solid matter to expression in unsized paper, repeat the treatment several times, and finally dissolve in hot ether, which deposits the stearin on cooling. This is concrete, white, opaque in mass, but of a pearly appearance as crystallized from ether, pulverizable, fusible at 66.5°C . (152°F .), soluble in boiling alcohol and ether, but nearly insoluble in those liquids cold, and quite insoluble in water. It consists of glyceryl and stearic acid in combination as a glyceride, $\text{C}_8\text{H}_7(\text{OC}_2\text{H}_4\text{H}_3\text{O})_3$, and has been formed synthetically by heating a mixture of these two materials to 280° to 300°C .

Margarin.—What was long known under this name was stated by Heintz in 1852 (*J. Pr. Chem.*, 56, p. 1) to be a mixture of stearin and palmitin, and this view is now universally accepted by all authorities.

The fixed oils are liable to certain spontaneous changes, which have been investigated by Pelouze and Boudet. It appears from their researches that the oils are accompanied, in the seeds which contain them, with principles which act as a ferment and cause the oils to resolve themselves spontaneously into the several fatty acids which they afford on saponification, and into glycerin. This change takes place in the seeds as soon as the cells containing the oils are broken, so as to permit the contact of the fermenting principle existing in the grain. The decomposition of fats by the action of enzymes has been made a working method capable of technical application, by Connstein, Hoyer and Wartenburg. The enzyme contained in the castor oil bean has been found best adapted for this. An emulsion of fats, water, 10 per cent. of ground castor oil beans and a small amount of free acid are used, when the decomposition proceeds rapidly. As rancidity in fats renders them altogether useless in pharmacy, and as it is not always readily discoverable by the senses in its earlier stages, it becomes desirable to possess a test by which it may be detected. Such a test is to be found, according to Thos. B. Groves, in potassium iodide, which is rapidly decomposed by the new principles developed, and the orange-brown discoloration produced by the liberation of the iodine indicates the existence of rancidity, and the degree of that discoloration, approximately, the extent of the change. The alteration of color is said by Groves to be plainly perceptible when only one-twentieth of rancid fat is present. The presence of water in a fatty oil favors the production of rancidity.

It is also extremely important to be able to protect fats against this change. The com-

plete exclusion of air, light, and moisture—and, when in relation to air this may not be entirely practicable, the destruction by heat of the ferment-germs contained in the air, by which the decomposition is often originated—will go far to effect this object; but it would often be very inconvenient, if not impossible, to carry these measures into complete effect, and hence the discovery of substances which may have the effect of retarding, if not wholly preventing, these fermenting processes, whether by the destruction of the ferment-germs or otherwise, is extremely desirable; this preservative effect has been known and practically used many years, and since the principle upon which they are supposed to act has been discovered the number has been extended. Thus, benzoin rubbed up with fats is well known to preserve them long against rancidity, and *benzoinated lard*, made by mixing ten per cent. of benzoin with melted lard, is one of the official preparations, and the buds of the poplar (*Populus nigra*) are perhaps still more effectual, as, according to Deschamps, lard impregnated with their virtues will keep good indefinitely. In the French Codex the poplar buds are employed in the *Pommade de Bourgeon de Peuplier*, in which 8 parts of the dried buds are used to 40 parts of the ointment, consisting of lard impregnated with the virtues of several narcotic substances, the fresh narcotic plants being boiled with lard until all their water is evaporated, and the buds afterwards digested in the strained liquid for 24 hours. Groves made experiments with many volatile oils and other analogous substances to test their preservative power, and, while many of them were found to have considerable effect, as cloves, Peruvian balsam, sassafras, guaiacum, and creosote, yet the one which appeared to act most efficiently was the *oil of pimenta*, and he proposes to add to the official *prepared lard* of the British Pharmacopœia either oil of pimenta or balsam of Peru, in the proportion of two drops to the ounce, in order to contribute to its preservation. (See *A. J. P.*, 1865, 54, 61.)

Animal fats are especially liable to become rancid when kept, and it is very desirable to obviate this effect, for, instead of having the mild demulcent properties which constitute their chief value, they become irritant, and unfit as vehicles for other substances to be applied to the skin. Hirzel says that animal fats may be kept in a good condition for a year by the following plan. Mix 14 pounds of the recently melted fat with 5 drachms of common salt and 15 grains of alum, in fine powder, heat till a scum is formed on the surface, separate the scum, and, when the clear liquid has cooled, wash it many times with water with malaxation, so as to remove all the salt, then evaporate the water at a heat insufficient to injure the fat. (*A. J. P.*, 1868, 334.)

The adulteration of the fixed oils may be effected in two ways,—by admixture with the

fatty oil of substances distinctly foreign to the fats, and by adding a cheaper or inferior oil to one of greater value. In the former case we may have the addition of paraffin wax, ceresine, mineral oils, neutral tar oils, resin oils, resin, and waxes. Of these, the first three are entirely unsaponifiable, resin oils contain but small quantities of saponifiable substances, waxes are partly saponifiable, and resin almost completely saponifiable. The determination of unsaponifiable matter is therefore of great importance. The common method for this is to saponify the suspected sample with alcoholic potassium hydroxide and then to shake out the unsaponifiable matter with ether or petroleum ether. From this solution, on evaporation, will be obtained the mineral, resin, or tar oils that may have been present. For these there are appropriate tests elsewhere noted. In case a cheaper oil or fat has been added for the purpose of adulterating a more valuable one, we must be guided by the determination of certain constants, such as those mentioned below by Cowley, or by the indication of certain qualitative color tests. The constants referred to are much more to be depended upon in such a case.

R. C. Cowley (*P. J.*, 1897, 331) regards the following as the most important determinations in examining fats and fixed oils. 1. Specific gravity. 2. Melting and solidifying points. 3. Melting and solidifying points of fatty acids. 4. Behavior with solvents. 5. The Hehner value. 6. The Reichert-Meissl value. 7. The saponification value. 8. The iodine value.

It is sometimes desirable to deprive the fixed oils of color. The following process for this purpose is recommended by Brunner. The oil is first brought to the state of emulsion by strongly agitating it with water rendered mucilaginous by gum or starch; the emulsion is treated for each part of oil with two parts of wood charcoal, previously well heated and coarsely powdered, the finer particles being sifted out; the pasty mass is then completely dried at a heat not exceeding 212° F., and exhausted by cold ether in a percolator; finally, the ethereal solution, having been allowed to stand, in order that any charcoal present in it may subside, is submitted to distillation, so as to separate the ether, and the oil remains colorless in the retort. (*J. P. C.*, Sept. 1858.) Berlandt recommends the following method. Shake strongly for some minutes 900 parts of the fixed oil with 120 parts of water holding in solution 3 parts of potassium permanganate, allow the mixture to stand for some hours in a warm place, and then filter. The oil becomes colorless. (*J. P. C.*, Oct. 1867.)

OLEA VOLATILIA. [*Olea Destillata*.]

Volatile Oils.

Olea Ætherea, Etherolea; Æthereal Oils, Essential Oils, Distilled Oils; Huiles Volatiles, Huiles Essentielles, Huiles Distillées, Essences, *Fr.*; Flüchtige Oele, Aetherische Oele, *G.*; Essenze, *It.*; Esencias, *Sp.*

These are sometimes called *distilled oils*, from the mode in which they are usually procured; sometimes *essential oils*, from the circumstance that they possess, in a concentrated state, the properties of the plants from which they are derived. They exist in all odoriferous vegetables, sometimes pervading the plant, sometimes confined to a single part; in some instances contained in distinct cellules, and preserved after desiccation, in others formed upon the surface, as in many flowers, and exhaled as soon as formed. Occasionally two or more are found in different parts of the same plant. Thus, the orange tree produces one oil in its leaves, another in its flowers, and a third in the rind of its fruit. In a few instances, when existing in distinct cellules, they may be obtained by pressure, as from the rind of the lemon and orange; but they are generally procured by distillation with water. (See page 819.) Some volatile oils, as those of bitter almond and mustard, are formed, during the process of distillation, out of substances of a different nature pre-existing in the plant.

The volatile oils are usually yellowish, but often brown, red, green, or blue, and occasionally colorless. There is reason, however, to believe that in all instances the color depends on foreign matter dissolved in the oils. Sépimus Piesse succeeded, by the fractional distillation of certain volatile oils, in separating a blue liquid, which, by repeated rectification, he has obtained quite pure. In this state it has the sp. gr. 0.910, and a fixed boiling point of 302.3° C. (572° F.), and yields a dense blue vapor having peculiar optical properties. He named this principle *azulene*, and believed that upon it depends the blueness of volatile oils wherever existing. The yellowness of the oils he ascribed to the resin resulting from their oxidation, the green and brown colors to a mixture of azulene and resin in various proportions. The formula of azulene he gave as $C_{16}H_{10}O$. (*Chem. News*, Nov. 21, 1863, p. 245.) Gladstone named this blue coloring constituent *cærulein*, and stated that it contains nitrogen and is colored green by acids and alkalies. The volatile oils differ from the fixed oils in not yielding glycerol when treated with alkalies.

The volatile oils have a strong odor, resembling that of the plants from which they were procured, though generally less agreeable. Their taste is hot and pungent, and, when they are diluted, is often gratefully aromatic. The greater number are lighter than water; some are heavier, and their sp. gr. varies from 0.847 to 1.17. They partially rise in vapor at ordinary temperatures, diffusing their peculiar odor, and are completely volatilized by heat. When distilled alone, they nearly always undergo partial decomposition. Heated in the open air, they take fire and burn with a bright flame attended with much smoke. Almost all those hitherto examined have the property of very decidedly deviating the plane of polarization of light, some in one direction, and some

in the other, and advantage may sometimes be taken of this property to detect adulterations of one of these oils with another. Exposed at ordinary temperatures, they absorb oxygen, assume a deeper color, become thicker and less odorous, and are ultimately converted into resin. This change takes place most rapidly under the influence of light. Before the alteration is complete, the remaining portion of oil may be recovered by distillation.¹

The volatile oils are largely hydrocarbons, although with these are alcohol- or ketone-like bodies called *camphors*, and products of oxidation known under the general name of resins, and undoubtedly formed from the hydrocarbons. These hydrocarbons are generally known as *terpenes*, from oil of turpentine, which is taken as a type. *Olea atherea sine terpeno* is the name proposed by Schweissinger for concentrated volatile oils made so by the removal of the non-fragrant hydrocarbon, and representing from two to thirty volumes of the ordinary essential oils. Thus, one volume of the concentrated oil represents two volumes of the oils of anise, cassia, fennel, gingergrass, mentha crispa, mentha piperita, cloves, sassafras, and star anise; two and one-half volumes of the oils of bergamot, caraway, and lavender; four volumes of cumin and rosemary; five volumes of thyme; six volumes of coriander; eight volumes of calamus; ten volumes of absinth; twenty volumes of juniper; thirty volumes of angelica, lemon, and orange. It is asserted that these concentrated oils are more permanent, more soluble in alcohol and in water, have a finer odor, and are of constant composition, thus enabling the specific gravity and boiling point to be used as tests of purity. They should be kept in the dark. (*Ph. Centralt.*, 1888, No. 25.) Under the name of "*terpeneless volatile oils*," similar products can now be found in the market; they are undoubtedly superior to the ordinary volatile oils both in odor and strength.

Wallach, to whom much of our knowledge on volatile oils is due, divides the hydrocarbons into classes, as follows:

1.—*True terpenes*, of the formula $C_{10}H_{16}$, of which there are two main groups: *a*, the *terpane* group, uniting with two molecules of haloid acid or four atoms of bromine; this group includes limonene, dipentene, sylvestrene, terpinolene, terpinene, and phellandrene, and its members boil between 175° and 185° C.; *b*, the *camphane* group, uniting with one molecule of haloid acid or two atoms of bromine; this group includes pinene, camphene, and fenchene, and its members boil between 151° and 161° C.

2.—*Hemiterpenes*, of the formula C_5H_8 , such as isoprene.

3.—*Polyterpenes*, such as cedrene, cubebene, etc., of the formula $C_{15}H_{24}$ (sesquiterpenes); colophene, of the formula $C_{20}H_{32}$; and caoutchouc, of the formula $(C_{10}H_{16})_x$.

Hydrocarbons other than those of the terpene class or derivable from them, occur very sparingly in the natural oils. Thus there is of the paraffin series of saturated hydrocarbons, *heptane*, C_7H_{16} , occurring in the oil from the *Pinus sabiniana*, or California digger pine, and solid hydrocarbons of the same series in oil of rose, and probably in oils of wintergreen and sweet birch. Of the benzene series there is a single representative in *cymene*, $C_{10}H_{14}$, found in the oils of the Thymus and Monarda species.

In addition to these naturally occurring hydrocarbons, there is a class of artificially prepared hydrocarbons known as *hydroterpenes*, such as dihydroadipentene from dipentene, menthene and carvomenthene from menthol and carvone.

The terpenes in general are practically insoluble in water, but soluble in alcohol, ether, chloroform, benzene, petroleum benzin, and the fixed and volatile oils. (Allen, *Com. Org. Anal.*, 2d ed., vol. ii. p. 418.)

Many of the essential oils, however, contain, or may even owe their essential character and their value to other constituents than hydrocarbons. We shall briefly notice the most important of these, either describing them or referring to other places in the text where they are already described, and shall then give a classification of the commonly known essential oils based upon the character of the most important compounds present in them.

I. Alcohols and Their Esters.

Geraniol	Terpineol
Linalool	Menthol
Citronellol	Borneol.

II. Aldehydes.

Citral	Cumic Aldehyde
Citronellal	Benzaldehyde
Salicyl Aldehyde	Cinnamic Aldehyde.

III. Ketones.

Methyl-nonyl-ketone	Camphor
Methyl-heptenone	Fenchone
Carvone	Thujone
Pulegone	Irone.
Menthone	

IV. Acids and Their Esters.

Methyl Salicylate	Methyl Anthranilate.
-------------------	----------------------

V. Phenols and Phenol Ethers.

Chavicol	Chavibetol
Methyl-chavicol	Safrol
Anethol	Iso-safrol
Thymol	Thymohydroquinone
Carvacrol	dimethyl ether
Eugenol	Asarol
Methyl-eugenol	Apiol.
Iso-eugenol	

¹ *Recovery of volatile oils from their resinified condition*.—A process for this purpose, employed by Curieux, is to treat the old resinified oil with a solution of borax and animal charcoal, these being first mixed to form a magma, the oil then added, and the mixture shaken for fifteen minutes. The borax unites with the resinous matter, and the magma, adhering to the sides of the vessel, leaves the oil clear and possessed of its original properties. (*A. J. P.*, Sept. 1858, p. 398.)

VI. Neutral Bodies, Oxides, etc.

Cineol (Eucalyptol).

VII. Sulphides and Sulphur Compounds.

Diallyl disulphide Allyl thiocyanate.

I. Alcohols and Their Esters.—This is an interesting group of open chain, unsaturated alcohols, which, with their esters and aldehydes, play a very important part in the composition of many essential oils. It is the geraniol, linalool and citronellol group.

1.—*Geraniol*, $C_{15}H_{26}O$, is a colorless liquid of a pleasant rose geranium odor, boiling at 229° to 230° C., under ordinary pressure, and at 120° C. under a pressure of 16 Mm. Its specific gravity is about 0.881 and its refractive index 1.4776. It is optically inactive. By careful oxidation with chromic trioxide it yields its aldehyde, citral, and by heating it in an autoclave with water to 200° C., it is partly converted into its isomer, linalool. Of the esters of geraniol the most important is the *geranyl acetate*. This is a fragrant oil of specific gravity 0.917, boiling at from 128° to 129° C., under a pressure of 16 Mm. It occurs naturally in several essential oils, and can be made artificially by the action of acetic anhydride upon geraniol.

2.—*Linalool*, $C_{10}H_{18}O$, is known in both of the optically active forms as well as in the inactive. It is a liquid having a pleasant odor, and boils under normal pressure at about 198° C., and at from 86° to 87° C. at 14 Mm. pressure. Its specific gravity ranges from 0.872 to 0.876, and its refractive index is 1.461. The most important of its esters is *linalyl acetate*, which occurs in many essential oils, as in oil of bergamot. It is an odoriferous liquid of the specific gravity 0.912, and boiling at from 105° to 108° C. at 11 Mm. pressure. It has also been prepared artificially.

3.—*Citronellol*, $C_{10}H_{20}O$, is found in oil of rose and in Spanish geranium oil. It is an odoriferous oil, boiling at from 117° to 118° C., under a pressure of 17 Mm.; specific gravity, 0.8565 at 17.5° C.; refractive index, 1.4566. When obtained from oil of rose it is levogyrate, while when obtained by reducing the aldehyde it is dextrogyrate; in most geranium oils both varieties exist.

A second group comprises the mono-cyclic alcohols, terpineol, which is unsaturated, and menthol, a saturated compound.

4.—*Terpineol*, $C_{10}H_{17}OH$, occurs in liquid and solid modifications, inactive, as well as in the two optically active, varieties. Besides occurring naturally it is made artificially by the dehydration of terpin hydrate, and is largely used in the perfume industry because of its lilac odor. Its most important ester is the acetate, which occurs in cajuput and cardamom oils.

5.—*Menthol*, $C_{10}H_{19}OH$, is now official, and will be found described on page 777. Two of its esters are recognized as occurring with it in peppermint oil, menthyl acetate and menthyl

iso-valerate. Of these the former is the more important. It is an oil having a penetrating odor, boiling at 224° C.

To a third group of compounds known as diacyclic, belongs:

6. *Borneol*, $C_{10}H_{18}O$.—This compound occurs naturally in both optically active modifications. It also occurs optically inactive. It forms crystalline masses, which, when quite pure, melt at 203° C. Borneol can be prepared artificially by reducing its ketone (camphor) with metallic sodium. In this case, however, there results a mixture of borneol and iso-borneol. Borneol forms a number of esters, of which *bornyl acetate* is the most important. This compound melts at 29° C., and has a specific gravity of 0.991 at 15° C. It is the characteristic constituent of the pine needle oils.

II. Aldehydes.—Of the alcohols just enumerated, only the first group are primary alcohols and will yield aldehydes. Thus, from geraniol, there is obtained by oxidation, citral the corresponding aldehyde, and from its isomer, linalool, the same.

1. *Citral*, $C_{10}H_{16}O$.—Although at one time called geranial, this compound is now universally known as citral, which indicates its importance in the oils of the *citrus* family. It is obtained most abundantly from lemon grass oil by the aid of the bisulphite process. It is an oily liquid, boiling at from 228° to 230° C., under ordinary pressure, and at 110° C., under 12 Mm. Its specific gravity is 0.8972 and its refractive index 1.493. It is optically inactive. Under the influence of alkalies, citral condenses with acetone with the elimination of water to form pseudo-ionone, $C_{15}H_{24}O$, which is converted into its isomer ionone by means of acids. Reduction with sodium produces the alcohol geraniol.

2.—*Citronellal*, $C_{10}H_{18}O$, the aldehyde of citronellol, occurs in several essential oils, as in citronella oil. It is an oily liquid of characteristic odor; specific gravity 0.8768, refractive index 1.4481. It is dextrogyrate.

Of the class of aromatic aldehydes, there are found in essential oils, salicyl aldehyde, cumic aldehyde, benzaldehyde, and cinnamic aldehyde.

3. *Salicyl Aldehyde*, $C_6H_4(OH)CHO$.—This body is an oily liquid of aromatic odor, boiling at 196° C., and having a specific gravity of 1.172. It occurs in the oils of the several varieties of *Spiræa*. It can also be formed by the oxidation of its alcohol saligenin, or by the action of chloroform and potassium hydroxide on phenol.

4. *Cumic Aldehyde*, $C_6H_4(C_2H_5)CHO$.—This is p-isopropyl-benzaldehyde, and is found in several essential oils, as in cumin oil. It is an aromatic oil, having a specific gravity of 0.973, and boiling at 235° C.

5. *Benzaldehyde*, C_6H_5CHO .—This is now official (see page 229).

6. *Cinnamic Aldehyde*, $C_6H_5CH:CH.CHO$. This is now official (see page 363).

III. Ketones.—This class of chemical compounds is largely represented in essential oils. Of aliphatic saturated ketones there is only one fairly important representative.

1.—*Methyl-nonyl-ketone*, $\text{CH}_3\text{.CO.C}_9\text{H}_{19}$, which is found in oil of rue, is a liquid of strong odor, boiling at 225°C . It solidifies when cooled, and melts at 13°C .

Of aliphatic unsaturated ketones there is also one occurring naturally.

2.—*Methyl-heptenone*, $\text{CH}_3\text{.CO.C}_6\text{H}_{11}$, is found in lemon grass oil and other oils, and results from the oxidation of citral or the distillation of cineolic anhydride.

The most commonly occurring ketones, however, belong to the cyclic compounds:

3. *Carvone*, $\text{C}_{10}\text{H}_{14}\text{O}$.—This compound, found in oils of caraway and dill, is a colorless oil boiling at 225°C . It is optically active, occurring in both forms. Its most interesting addition compound is that with hydrogen sulphide; this is obtained in crystals, decomposing with alcoholic potassium hydroxide and liberating pure carvone. When heated with glacial phosphoric acid, it is changed into the isomeric carvacrol, a phenol compound.

4. *Pulegone*, $\text{C}_{10}\text{H}_{16}\text{O}$.—This characteristic ketone of pennyroyal oil is a liquid boiling at 221°C , and having a specific gravity of 0.936. An isomeric body, iso-pulegone, has been obtained artificially.

5. *Menthone*, $\text{C}_{10}\text{H}_{18}\text{O}$.—This occurs along with the corresponding secondary alcohol menthol, in oil of peppermint. It is an oily liquid boiling at 208°C , with a specific gravity of 0.894. By the action of oxidizing agents it can be converted into thymol, $\text{C}_{10}\text{H}_{14}\text{O}$.

To the class of bicyclic ketones belong the following isomeric bodies:

6. *Camphor*, $\text{C}_{10}\text{H}_{16}\text{O}$.—This most important compound of the ketone class is official, and is described on page 274.

7. *Fenchone*, $\text{C}_{10}\text{H}_{16}\text{O}$.—This ketone occurs as dextro-fenchone in oil of fennel, and as lævo-fenchone in oil of thuja. When purified, it forms an oil of camphoraceous odor, boiling at 193°C , and having a specific gravity of 0.946.

8. *Thujone*, $\text{C}_{10}\text{H}_{16}\text{O}$.—This ketone is found in oils of thuja, tansy, wormwood and sage, and is identical with the bodies formerly known as *tanacetone* and *salvone*. It is an optically active liquid, boiling at from 200° to 203°C . and having a specific gravity of 0.917.

A more complex ketone yet to be noted is:—

9. *Irone*, $\text{C}_{13}\text{H}_{20}\text{O}$.—The characteristic constituent of orris oil, to which also the violet odor is due, is irone. It is an oil almost insoluble in water, but readily soluble in alcohol, boiling at 144°C . at 16 Mm., and having a specific gravity of 0.939 at 20°C . In the attempt to effect the synthesis of irone, Tiemann and Krüger obtained an isomeric body *ionone*, which is now used as the artificial violet odor.

IV. Acids and Their Esters.—While esters of several of the fatty acids, both saturated and

unsaturated, are found in the essential oils, the compounds are not so distinctive or characteristic, that they require mention here. Of aromatic acids and their esters there are several of importance, however, comprising the most valuable constituents of the oil in which they occur.

1.—*Methyl Salicylate* is the chief constituent of the oils of wintergreen and sweet birch. As it is now official as a pure compound, it is described on page 778.

2. *Methyl Anthranilate* (*o-amidobenzoate*), $\text{C}_6\text{H}_4(\text{NH}_2)\text{COOCH}_3$.—This is the odoriferous constituent of neroli oil. It is an oil solidifying at low temperatures in crystals melting at 24.5°C ., and boiling at 127°C . at 11 Mm. Its specific gravity is 1.163 at 26°C . It is strongly fluorescent and has a powerful neroli odor.

V. Phenols and Phenol Ethers.—This is an important class, largely represented in the volatile oils. Of monatomic phenols there are:

1. *Chavicol* (*para allyl-phenol*), $\text{C}_6\text{H}_4(\text{OH})\text{C}_3\text{H}_5$.—This occurs in the oil of *Chavica Betle*, and is a colorless liquid having a strong odor and a specific gravity of 1.035 at 20°C ., boiling at 237°C . Still more abundantly formed in nature is its methyl ether, which is:

2. *Methyl-chavicol*, $\text{C}_6\text{H}_4(\text{OCH}_3)\text{C}_3\text{H}_5$.—This occurs in the oils of anise, star anise, sweet-basil, bay, etc. It is a colorless liquid of an anise-like odor, boiling at from 215° to 216°C ., and having a specific gravity of 0.946.

3.—*Anethol*, $\text{C}_6\text{H}_4(\text{OCH}_3)\text{C}_3\text{H}_5$, is the methyl ether of *p-propenyl-phenol*, and is therefore isomeric with methyl-chavicol. It can be formed from the latter by heating it with alcoholic potassium hydroxide. It is the most abundant constituent of the oils of anise, star anise and fennel. It forms white scales melting at 21°C ., and boiling at 232°C .

4. *Thymol* (*methyl-propyl-phenol*), $\text{C}_6\text{H}_3(\text{OH})(\text{C}_3\text{H}_7)1:3:4$.—This is one of the best known of the phenols occurring in volatile oils. As it is official its description will be found under *Thymol*.

5. *Carvacrol* (*methyl-propyl-phenol*), $\text{C}_6\text{H}_3(\text{CH}_3)(\text{OH})\text{C}_3\text{H}_71:2:4$.—This important phenol, occurring in oils of marjoram and savory, is isomeric with thymol. It is a thick oil, solidifying at 0°C . and boiling at 236°C . It can be prepared artificially by heating carvone, an isomeric ketone, with phosphoric acid or by heating camphor with iodine.

Of diatomic phenols and their ethers, there are the following:

6.—*Eugenol*, $\text{C}_6\text{H}_3(\text{OH})(\text{OCH}_3)\text{C}_3\text{H}_54:3:1$, is the methyl ether of allyl-dioxybenzene. It occurs in the oils of cloves, allspice, bay, Ceylon cinnamon and cinnamon leaves. As it is now official, its description will be found on page 456.

7.—*Methyl-eugenol*, $\text{C}_6\text{H}_3(\text{OCH}_3)_2\text{C}_3\text{H}_5$, is found together with eugenol in oil of bay.

8.—*Iso-eugenol* is the methyl ether of propenyl-dioxybenzene, and is produced from eu-

genol when the latter is heated with alcoholic potassium hydroxide. It is used in the manufacture of artificial vanillin.

9.—*Chavibetol* is another isomer of eugenol, and occurs with chavicol in oil of betel leaves.

10.—*Safrol*, $\text{C}_6\text{H}_5\text{O} > \text{CH}_2.\text{C}_6\text{H}_5$, is the methylene ether of allyl-dioxybenzene. It is found quite largely in the oils of sassafras, camphor, etc. As it is now official its description will be found under *Safrolum*.

11.—*Iso-safrol* is the methylene ether of propenyl-dioxybenzene, and is produced from safrol by heating the latter with alcoholic potassium hydroxide. It is used in the manufacture of *piperonal* (artificial heliotropin).

12.—*Thymohydroquinone dimethyl-ether*, $\text{C}_6\text{H}_2(\text{OCH}_3)_2.\text{CH}_3.\text{C}_6\text{H}_5$, constitutes the bulk of the oil of *arnica root*. It is a liquid distilling at from 248° to 250° C.

Of triatomic phenols and their ethers, the representative is:

13. *Asarol*, $\text{C}_6\text{H}_2(\text{C}_6\text{H}_5)(\text{OCH}_3)_3$.—This is the trimethyl ether of propenyl-trioxybenzene. It forms the solid constituent of the oil of *Asarum europæum*, and occurs in prisms melting at 61° C., and boiling at from 295° to 296° C. It has also been made synthetically.

Of tetratomic phenols and their ethers, there is also a representative, as follows:

14.—*Apiol*, $\text{C}_{12}\text{H}_{14}\text{O}_4$, is the dimethyl-methylene ether of allyl-tetroxybenzene. It occurs in two isomers—the apiol from oil of parsley and dill apiol from some varieties of oil of dill. Of these, the former is a crystalline solid melting at 30° C. and boiling at 294° C., and the latter is an oily liquid boiling at 288° C.

VI. Neutral Bodies, Oxides, etc.—One important compound of frequent occurrence in volatile oils has not been classified under any of the preceding groups, for the reason that it is relatively inert in a chemical way and is considered as an oxide of neither distinct acid or basic character.

1. *Cineol* (*Eucalyptol*), $\text{C}_{10}\text{H}_{18}\text{O}$.—This is found in nature in large amounts in eucalyptus oil (hence the name “eucalyptol” sometimes given to it), in cajuput oil (hence the name of “cajuputol”), in lavender, wormseed, and other oils. As it is now official under the name of *eucalyptol*, its description will be found on page 453.

VII. Sulphides and Sulphur Compounds.

1.—*Di-allyl disulphide*, $\text{C}_6\text{H}_{10}\text{S}_2$, is a constituent of oil of garlic and occurs in many oils belonging to the *Cruciferae*. It is a liquid of very unpleasant odor, boiling at 140° C.

2.—*Allyl Thiocyanate*, $\text{C}_3\text{H}_5.\text{NSC}$, is the principal constituent of the volatile oil of mustard. It is, however, a decomposition product of the glucoside potassium myronate, which breaks up under the influence of the ferment myrosin. The allyl thiocyanate can also be obtained artificially by distilling allyl iodide or bromide with alcoholic potassium thiocyanate. This artificial product is largely sold in place of the

natural oil. It is a liquid having a very unpleasant odor, boiling at 151° C., and having a specific gravity of 1.017 at 10° C.

CLASSIFICATION.

Classification of the more commonly occurring volatile oils.—In considering the question of classifying the volatile oils, two methods of arrangement naturally suggest themselves, viz. a classification according to the botanical natural orders to which they belong, and a chemical classification based on the most important chemical constituents of the oils themselves. While the first of these is the more readily made, it suffers from the disadvantage of being cumbrous and less readily understood except by the botanist. On the other hand, the second plan shows at a glance the sources of the valuable odoriferous and medicinally and technically important constituents for which the volatile oils are largely used. That it has not been generally adopted is no doubt due to the fact that many of the oils contain several different constituents of value, and it is therefore difficult to make an assignment of some of them to individual chemical groups. Nevertheless, it is believed that the chemical classification adopted here will be found to have practical value for reference.

Group I.—Oils containing mainly Terpenes and Sesquiterpenes.

Oil of Cedarwood; cedrene and cedrol.
Copaiba Balsam; caryophyllene.
Cubeb; cadinene and cubeb camphor.
Dog Fennel; phellandrene.
Fleabane; d-limonene.
Galbanum; pinene and cadinene.
Ginger; sesquiterpene and phellandrene.
Hemp; cannibene and other terpenes.
Hops; humulene and tetrahydrocymene.
Myristica; terpenes and myristicol.
Orange; limonene with small amount of citral and citronellal.
Turpentine; pinene and sylvestrene.

Group II.—Oils containing mainly Alcohols and their esters.

a. Aliphatic saturated alcohols:
Oil of Heracleum; octyl alcohol and octyl ester.
b. Aliphatic unsaturated alcohols:
Oil of Bergamot; linalool and linalyl acetate.
Coriander; linalool and d-pinene.
Geranium; geraniol and geranyl esters.
Lavender; linalyl acetate and geraniol.
Lime; linalyl acetate and limonene.

Group II.—(Continued.)

- Linaloes; linalool and geraniol.
- Petit Grain; linalool and linalyl acetate.
- Rose; geraniol and citronellol with esters.
- c. Monocyclic and dicyclic alcohols.
- Oil of Angostura; galipol, galipene, and cadinene.
- Fir Cones; bornyl acetate and terpenes.
- Golden Rod; borneol and bornyl esters.
- Juniper Berries; juniper camphor and cadinene.
- Ledum; ledum camphor.
- Lovage; terpineol.
- Mace; myristic acid.
- Patchouli; patchouli camphor and cadinene.
- Peppermint; menthol and menthone.
- Pine Needles; bornyl acetate and terpenes.
- Rosemary; borneol and bornyl acetate.
- Sandalwood; santalol and esters.
- Savin; sabinol and sabinyl acetate.
- Valerian; borneol and bornyl esters.
- d. Aromatic Alcohols and Esters:
- Oil of Jasmine; benzyl acetate and benzyl alcohol.

Group III.—Oils containing Aldehydes as characteristic constituents.

- a. Aliphatic unsaturated aldehydes:
- Oil of Citron peel; citral and limonene.
- Citronella; citronellal and geraniol.
- Lemon; Citral and citronellal.
- Lemon grass; citral, citronellal, and methyl-heptenone.
- Verbena; citral.
- b. Aromatic aldehydes:
- Oil of Bitter Almond; benzaldehyde.
- Cassia; cinnamic aldehyde.
- Cinnamon; cinnamic aldehyde and eugenol.
- Cumin; cumic aldehyde.
- Meadow Sweet; salicyl aldehyde.

Group IV.—Oils containing Ketones as characteristic constituents.

- a. Aliphatic saturated aldehydes:
- Oil of Rue; methyl-nonyl-ketone.
- b. Aliphatic unsaturated aldehydes:
- Oil of Lemon grass; methyl-heptenone.
- c. Monocyclic and dicyclic ketones:
- Oil of Artemisia; thujone.
- Camphor; camphor.
- Caraway; carvone and limonene.
- Dill; carvone and limonene.
- Orris; irone.
- Pennyroyal; pulegone.

Group IV.—(Continued.)

- Peppermint; menthone and menthol.
- Sage; thujone with borneol and cineol.
- Spear-mint; carvone.
- Tansy; thujone with borneol.
- Thuja; thujone and fenchone.
- Wormwood; thujone and thujyl alcohol.

Group V.—Oils containing Acids and Esters.

- a. Aliphatic Acids:
- Oil of Angelica; methyl-ethyl-acetic esters.
- Calamus; heptylic and palmitic acid and esters.
- Cardamom; acetic esters and cineol.
- German Chamomile; caproic acid esters.
- Roman Chamomile; butyric, angelic and tiglic esters.
- b. Aromatic acids and esters:
- Oil of Neroli; o-amido-benzoic-methyl ester.
- Sweet Birch; methyl salicylate.
- Gaultheria; methyl salicylate.
- c. Undetermined acids:
- Oil of Celery; sedanolide and lactone.
- Elecampane; alantioic acid and lactone.

Group VI.—Oils containing Phenols and Phenol Ethers.

- a. Monatomic phenols and their ethers:
- Oil of Ajowan; thymol and cymene.
- Anise; anethol and methyl-chavicol.
- Betel; chavicol and methoxy-chavicol.
- Fennel; anethol and fenchone.
- Marjoram; carvacrol and linalool.
- Savory; carvacrol, pinene, and cymene.
- Star Anise; anethol, methyl-chavicol and safrol.
- Sweet Basil; Methyl-chavicol and d-linalool.
- b. Diatomic phenols and their ethers:
- Oil of Arnica Root; thymohydroquinone dimethyl-ether.
- Bay; eugenol, methyl-eugenol and methyl-chavicol.
- Camphor; safrol, eugenol and camphor.
- Cascarilla Bark; eugenol and terpenes.
- Cinnamon Leaf; eugenol and cinnamic aldehyde.
- Cloves; eugenol and sesquiterpene.
- Pimenta; eugenol and sesquiterpene.
- Sassafras; safrol and camphor.

Group VI.—(Continued.)**c. Triatomic phenols and their ethers:**

Oil of Asarum; asarol and methyl-eugenol.

Matico; asarol.

d. Tetratomic phenols and their ethers:

Oil of Parsley; apiol.

Group VII.—Oils containing Neutral Bodies.

Oil of Cajuput; cineol, terpineol and terpenyl acetate.

Eucalyptus; cineol, pinene, and aldehydes.

Laurel Leaves; cineol and pinene.

Myrtle; cineol, d-pinene and dipentene.

Wormseed; cineol and dipentene.

Group VIII.—Oils containing Sulphur.

Oil of Asafoetida; sulphides and pinene.

Garlic; diallyl-disulphide and allyl-propyl sulphide.

Mustard; allyl-thiocyanate, allyl-cyanide and carbon disulphide.

Onion; allyl-propyl sulphide.

Properties.—Volatile oils are slightly soluble in water. Agitated with this fluid they render it milky, but separate upon standing, leaving the water impregnated with their odor and taste. This impregnation is more complete when water is distilled with the oils, or from the plants containing them. Trituration with magnesia or its carbonate renders them much more soluble, probably in consequence of their minute division. The intervention of sugar also greatly increases their solubility, and affords a convenient method of preparing them for internal use. The oils which contain no oxygen are scarcely soluble in diluted alcohol, and, according to De Saussure, their solubility generally in this liquid is proportionate to the oxygen which they contain. The volatile oils dissolve sulphur and phosphorus with the aid of heat, and deposit them on cooling. By long boiling with sulphur they form brown, unctuous, fetid substances, formerly called *balsams of sulphur*. They absorb chlorine, which converts them into resin and then combines with the resin. Iodine produces a similar effect. They are decomposed by the strong mineral acids, and unite with several of the acids from the vegetable kingdom. When treated with a caustic alkali, some of them are converted into resin, which unites with the alkali to form a kind of soap. Several of the metallic oxides, and various salts which easily part with oxygen, convert them into resin. The volatile oils dissolve many of the proximate principles of plants and animals, such as the fixed oils and fats, resins, camphor, and several of the alkaloids. Exposed to air and light, they acquire a decolorizing property, analogous to that of chlorine, which is ascribed by Faraday to their combination with the ozonized oxygen of the atmosphere.

Adulterations.—The volatile oils are often sophisticated. Among the grosser adultera-

tions are fixed oils, resinous substances, and alcohol, but the most dangerous are those made by mixing the pure oil with the cheaper volatile oils and terpenes and fractions from other oils like limonene. The presence of the fixed oils may be known by the permanent greasy stain which they leave on paper, while that occasioned by a pure volatile oil disappears entirely when exposed to heat. They may also in general be detected by their comparative insolubility in alcohol. Both the fixed oils and resins are left behind when the adulterated oil is distilled with water. If alcohol be present, the oil will become milky when agitated with water in a graduated tube, and after the separation of the liquids the water will occupy more space and the oil less than before. The following method of detecting alcohol was proposed by Beral. Put twelve drops of the suspected oil in a perfectly dry watch-glass, and add a piece of potassium about as large as the head of a pin. If the potassium remains for twelve or fifteen minutes in the midst of the liquid, there is either no alcohol present, or less than 4 per cent. If it disappears in five minutes, the oil contains more than 4 per cent. of alcohol; if in less than a minute, 25 per cent. or more. Borsarelli employs calcium chloride for the same purpose. This he introduces in small pieces, well dried and perfectly free from powder, into a small cylindrical tube, closed at one end, and about two-thirds filled with the oil to be examined, and heats the tube to 212° F., occasionally shaking it. If there is considerable proportion of alcohol, the chloride will be entirely dissolved, forming a solution which sinks to the bottom of the tube; if only a very small quantity, the pieces will lose their form, and collect at the bottom in a white adhering mass; if none at all, they will remain unchanged. (*J. P. C.*, xxvi. 429.) J. J. Bernoulli proposes as a test dry potassium acetate, which remains unaffected in a pure oil, but will be dissolved if alcohol be present, and form a distinct liquid. (See *A. J. P.*, xxv. 82.) Distillation, catching the first portion, and testing for alcohol by the iodoform reaction, will detect very small additions of alcohol. The most dangerous adulterant of volatile oils is a liquid sold under some "fancy name," found in the markets of London and other large cities, and recommended for "reducing" essential oils; one specimen examined by John Barclay (*P. J.*, 1896, 463) had a delicate odor, and could be mixed with oils of lemon and bergamot without being detected by odor or taste. It was believed to be a *lavopinene*. There are good reasons for believing that similar liquids are used to an enormous extent.

Sometimes volatile oils of little value are mixed with the more costly. The taste and odor afford in this case the best means of detecting the fraud. The specific gravity of the oils may also serve as a test of purity. When two oils, of which one is lighter and the other

heavier than water, are mixed, they may be separated by long agitation with this fluid, and will take a place corresponding to their respective specific gravities, but it sometimes happens that an unadulterated oil may thus be separated into two portions. The difference of apparent effect produced by iodine with the several oils has been proposed as a test, and bromine was employed for the same purpose by John M. Maisch, who used both these tests preferably in the state of ethereal solution, which, as it is liable to spontaneous change by keeping, should be prepared when wanted for use. According to Liebig, when iodine is made to act on a volatile oil, a portion of it combines with the hydrogen of the oil, forming hydriodic acid, while another portion takes the place of the lost hydrogen. Oil of turpentine may be detected by remaining in part undissolved when the suspected oil is treated with three or four times its volume of alcohol of the sp. gr. 0.84; or, according to Mero, by causing the suspected oil, when agitated with an equal measure of poppy oil, to remain transparent, instead of becoming milky, as it would do if pure. The latter test will not apply to the oil of rosemary. (*J. P. C.*, 3e ser., vii. 303.) G. S. Heppé suggests a very delicate test of oil of turpentine and most other non-oxygenated oils, when used to adulterate one of the oils containing oxygen. A piece of copper nitroprusside, of the size of a pin's head, is put into a little of the suspected oil in a test-tube, and heated until the liquid begins to boil. The boiling must be continued only a few seconds. If the oil be pure and oxygenated, the copper nitroprusside will become black, brown, or gray; if oil of turpentine or other non-oxygenated oil be present, the deposit will be green or bluish green, and the supernatant liquid colorless or yellowish. (*Chem. Gaz.*, April 15, 1857, p. 155; *Proc. A. Ph. A.*, 1858, p. 344.)

The different relations of the volatile oils to polarized light may, to a certain extent, be made available for the detection of adulterations, especially where the action of the adulterating oil is in an opposite direction to that of the oil adulterated. Thus, the oils of juniper, lavender, and rosemary, rotate the plane of polarization to the left, while American oil of turpentine rotates it to the right; and if this should be added to one of the other oils it might in some degree neutralize their action, and thus offer one means for its detection. Unfortunately, the French oil of turpentine, from the juice of the *Pinus maritima*, acts strongly in the opposite direction. But the very strength of its left-rotatory power might lead to its detection by the abnormal increase of this power which it would impart to the oils in question. Synthetic or artificial volatile oils are now largely manufactured. They vary greatly at times in their resemblance to the natural products. They will be considered under their respective titles elsewhere, a number having received official recognition.

Volatile oils may be preserved without change in small, well-stoppered amber-colored bottles, entirely filled with the oil, and secluded from the light.

Manufacture.—Most of the volatile oils may be prepared by the general formula of the U. S. P. 1870: "Put the substance from which the Oil is to be extracted into a retort or other vessel suited for distillation, and add enough water to cover it; then distil by a regulated heat into a large refrigeratory. Separate the Distilled Oil from the water which comes over with it."¹ U. S. 1870.

Under the general observations on the *Aquæ*, or *Waters*, will be found remarks upon the use of steam in preparing the Distilled Waters, which are to a considerable extent applicable also to the volatile oils.

The substances from which the volatile oils are extracted may be employed in either the recent or the dried state. Certain flowers, however, such as orange flowers and roses, must be used fresh, or preserved with salt or by means of glycerin, as they afford little or no oil after desiccation. Most of the aromatic herbs, also, as peppermint, spearmint, pennyroyal, and marjoram, are usually distilled while fresh, although it is thought by some that when moderately dried they yield a larger and more grateful product. Dried substances, before being submitted to distillation, require to be macerated in water until they are thoroughly penetrated by this fluid, and to facilitate the action of the water it is necessary that, when of a hard or tough consistence, they should be properly comminuted by slicing, shaving, rasping, bruising or other similar mechanical operation.

The water which is introduced into the still with the substance answers the double purpose of preventing the decomposition of the vegetable matter by regulating the temperature, and of facilitating the volatilization of the oil, which, though in most instances readily rising with the vapor of boiling water, requires, when distilled alone, a considerably higher temperature, and is at the same time liable to be partially decomposed. Some oils, however, will not ascend readily with steam at 100° C. (212° F.), and in the distillation of these it is customary to use water saturated with common salt, which does not boil under 110° C. (230° F.). Recourse may also be had to a bath of strong solution of calcium chloride, or to an oil bath. Other oils, again, may be volatilized with water at a temperature below the boiling point, and, as heat exercises an injurious influence over the oils, it is desirable that the distillation should be effected at as low a temperature as possible. To prevent injury from heat, it has been

¹ A large proportion of the volatile oils of European commerce is produced in Grasse, a town of France, twenty-five miles west of Nice. For an elaborate article on this industry and methods of preparation, see *A. Pharm.*, xxii. 473, abstracted in the *P. J.*, vol. xv. 468.

recommended to suspend the substance containing the oil in a wire basket, or to place it upon a perforated shelf, in the upper part of the still, so that it may be penetrated by the steam, without being in direct contact with the water. Another mode of effecting the same object is to distil it *in vacuo*. Duncan stated that the most elegant volatile oils he had even seen were prepared in this manner by Barry, the inventor of the process. The employment of steam heat also prevents injury, and the best volatile oils are now prepared by manufacturers in this way. Steam can be very conveniently applied to this purpose by causing it to pass through a coil of tube, of an inch or three-quarters of an inch bore, placed in the bottom of a common still. The end at which the steam is admitted enters the still at the upper part, and the other end, at which the steam and condensed water escape, passes out laterally below, being furnished with a stopcock, by which the pressure of the steam may be regulated and the water drawn off when necessary. In some instances it is desirable to conduct the steam immediately into the still near the bottom, by which the contents are kept in a state of brisk ebullition. This method is used in the preparation of the oil of bitter almond. The same method is applicable to the preparation of distilled waters.

The quantity of water added is not a matter of indifference. An excess above what is necessary acts injuriously by holding the oil in solution when the mixed vapors are condensed, and if the proportion be very large, it is possible that no oil whatever may be obtained separate. On the contrary, if the quantity be too small, the whole of the oil will not be distilled, and there will be danger of the substance in the still adhering to the sides of the vessel and thus become burnt. (See page 185.) Enough water should always be added to cover the solid material and prevent the latter accident. Dried plants require more water than the fresh and succulent. The whole amount of material in the still should not exceed three-fourths of its capacity, as otherwise there would be danger of the liquid boiling over. The form of the still has an influence over the quantity of water distilled, which depends more upon the extent of surface than upon the amount of liquid submitted to evaporation. By employing a high and rather narrow vessel we may obviate the disadvantage of an excess of water. (See p. 522.) Sometimes the proportion of oil in the substance employed is so small that it is wholly dissolved in the water distilled, even though the proportion of the liquid in the still is not greater than is absolutely essential. In this case it is necessary to redistil the same water several times from fresh portions of the plant, until the quantity of oil exceeds the solvent power of the water. This process is called *cobobation*.

The more volatile of the oils pass with facility along with the steam into the neck of the

common still, but some which are less volatile are apt to condense in the head and thus return into the still. For the distillation of the latter, a copper still should be employed having a very low head. (See page 532.) As, after the distillation of any one oil, it is necessary that the apparatus should be thoroughly cleansed before being used for the preparation of another, it is better that the condensing tubes should be straight, rather than spiral as in the ordinary still. It should be recollected, moreover, that certain oils, such as those of anise and fennel, are rendered solid by a comparatively slight reduction of temperature, and that in the distillation of these the water employed for refrigeration should not be below 5.5° C. (42° F.).

The mixed vapors are condensed into a milky liquid, which is collected in a receiver, and, after standing for some time, separates into the oil and a clear solution of it, the former floating on the surface, or sinking to the bottom, according as it is lighter or heavier than water. The distillation should be continued so long as the liquid coming over has a milky appearance.

The last step in the process is to separate the oil from the water. For this purpose the *Florentine receiver*¹ may be used. This is a conical glass vessel, broad at the bottom and narrow towards the top, and very near its base furnished with a tubulure or opening, to which is adapted, by means of a pierced cork, a bent tube so shaped as to rise perpendicularly to seven-eighths of the height of the receiver, then to pass off from it at right angles, and near the end to bend downward. The condensed liquid being admitted through the opening at the top of the receiver, the oil separates, and, rising to the top, occupies the upper narrow part of the vessel, while the water remains at the bottom, and enters the tube affixed to the receiver. When the surface of the liquid attains in the receiver a higher level than the top of the tube, the water will necessarily begin to flow out through the latter, and may be received in bottles. The oil thus accumulates as long as the process continues, but it is evident that the plan is applicable only to the oils lighter than water. For the heavier oils, cylindrical vessels may be employed, to be renewed as fast as they are filled; but, as all the water cannot be removed by these plans, it is necessary to resort to some other method of effecting a complete separation. An instrument called a *separator* is usually employed for this purpose. It consists of a glass funnel, or a globular vessel, furnished with a stopper, and prolonged at the bottom into a very narrow tube. The lower opening being closed, the mixed liquids are introduced and allowed to stand until they

¹ For illustrations of this, and other forms of receivers, for collecting and separating immiscible liquids, see Remington's *Practice of Pharmacy*, 4th edition, p. 224.

separate. The orifice at the bottom is then opened, and, the stopper at the top being a little loosened, so as to admit the air, the heavier liquid slowly flows out, and may be separated to the last drop from the lighter, which floats above it. If the oil is heavier than the water, it passes out of the separator; if lighter, it remains within. According to George Leuchs, all oils obtained by distillation with water, even when perfectly clear, contain some water. (*A. J. P.*, 1873, p. 110.)

The water saturated with oil should be preserved for use in future distillations, as it can dissolve no more of the oil. One or more volatile acids are frequently found in the distilled water, as acetic, butyric, or valerianic, and Wunder has detected all three of these acids in the water distilled from chamomile flowers. (*J. Pr. Chem.*, lxiv. 499.) For an illustration of a cheap apparatus for distilling volatile oils by steam under slight pressure, see *Proc. A. Ph. A.*, 1894, 680.

According to Overbeck, all the volatile oils may be decolorized by distilling them from an equal weight of poppy seed oil and a saturated solution of common salt. (*A. Pharm.*, lxxiv. 149.)

When first procured, the oils have a disagreeable empyreumatic odor, from which they may be freed by allowing them to stand for some days in vessels loosely covered with paper. They should then be filtered and introduced into small opaque bottles, which should be well stoppered so as to exclude the air. When altered by exposure to air, they may sometimes be restored to their original appearance and quality by agitation with a little recently heated animal charcoal, and the same method may be employed for freeing them from adhering water.

The volatile oils have the medicinal properties of the plants from which they are derived, and, as their remedial application has been mentioned under the heads of these plants respectively, it is unnecessary to treat of it in this place. They may be administered upon a lump of sugar; or triturated with at least ten times their weight of sugar, forming *oleo-saccharates*, which are then dissolved in water; or made into emulsions with water, sugar, and gum arabic. In making emulsions with volatile oils, it has been recommended first to dissolve them in one of the fixed oils, the oil of almond for example, and then to emulsify the oleaginous solution with syrup and gum arabic. For 100 parts of water, 15 of the almond oil in which the volatile oil is to be dissolved, 10 of powdered gum arabic, and 25 of syrup may be taken. (*J. P. C.*, Juin, 1864, p. 461.) The volatile oils are often kept dissolved in alcohol under the name of *essences*.¹ The following suggestions on pre-

paring emulsions of the volatile oils may be useful. Oil of turpentine and other volatile oils, to be emulsified in quantity, are most successfully treated by rubbing them with the powdered gum, and, when intimately mixed, adding at once, with rapid trituration, one and a half times the weight of the gum used, of water. By this treatment the volatile oil is thoroughly divided before contact with water, and, if the quantity of water indicated be added at once, the emulsion will have the right preliminary consistence, and unite with and emulsify the volatile oils. If, however, but a little water be added, this will seize on the gum, forming a pilular mass, and throwing the volatile oil out of union. Such an emulsion is more permanent when a little fixed oil is used.

OLEATA

OLEATES

(ô-lê-â'ta)

Oléates, *Fr.*; Oleate, *G.*

The oleates are a class of preparations which were introduced to the medical profession by John Marshall, F.R.S., in 1872. They are usually solutions of certain bases in oleic acid, and are made by triturating the solid substance with the oleic acid until it is dissolved. Whenever it is possible, the application of heat should be avoided, and it has been observed that the freshly precipitated oxides of the metals dissolve more readily than those which are old. The title *oleate* is probably the best that could be devised, although it must be understood that, as found in the Pharmacopœias, they are not pure chemical compounds, but merely compounds of the oxides or the alkaloids; as the case may be, with oleic acid dissolved in a great excess of the latter.²

be separated by distillation. The process consists in exposing the fatty matter, placed in layers, in suitable frames, to the exhalations from the flowers, which are absorbed, and give their characteristic odor to the fat. Another plan is to expose alternate layers of the flowers, and of cotton impregnated with bland fixed oil, to the sun, and afterwards to express the oil from the cotton. (*A. J. P.*, xxix. 551.) The French sometimes give to the spirituous solutions made by extracting the odors from fats and oils with alcohol the name of *Essences*.

²L. Wolff published a process for obtaining the oleates, as follows: One part of Castile soap (sodium oleopalmate) is dissolved in eight parts of water, the solution so obtained is allowed to cool and stand for 24 hours, when there will be a considerable deposit of sodium palmitate, while the supernatant liquor, containing mostly sodium oleate, is drawn off and then decomposed with a concentrated solution of a metallic salt which, if obtainable, should contain no free acid to prevent the formation of free oleo-palmitic acid. The heavy deposit of oleo-palmitate so derived is drained off, pressed out in the strainer, and the adherent water evaporated in a water bath; after this it is dissolved in about six to eight times its quantity of petroleum benzine, while the insoluble palmitate is left to subside, while the solution of oleate decanted therefrom is filtered off. The benzine evaporated will yield an oleate that is entitled to that name, as it is a chemical combination and will remain stable and efficacious. The oleates, so prepared, present an amorphous appearance, while the palmitates are of a crystalline character. (*A. J. P.*, 1881, p. 545.)

¹*Enfleurage*.—This term is applied by the French to the impregnation of fixed oils and fatty matters with the odors of certain sweet scented plants, such as jasmine, tuberose, and mignonette, the oils of which are so delicate and fugitive that they cannot well

Oleates may be made either by direct combination of the ingredients or by double decomposition. When made by the latter method, a good quality of oleic acid should be treated with the proper quantity of solution of sodium hydroxide, to saponify it, any excess of the alkali being neutralized with a little tartaric acid. This soap solution is preferably used diluted.¹

J. M. Good, in making the oleates of the alkaloids, proposes the use of sufficient oleic acid to dissolve the alkaloid and then diluting the solution with a bland fixed oil, such as almond oil. (*Proc. Missouri Pharm. Association*, 1891, p. 65.)²

¹ *Sulpholeic Acid and Sulpholeates*.—Sulpholeates, or salts produced by the combination of alkalies with sulpholeic acid, have come into use on account of their ability to dissolve many substances or hold them in suspension as emulsifying agents. Sulpholeic acid is prepared as follows. Castor, almond, or other fixed oil is gradually mixed with 30 or 40 parts of concentrated sulphuric acid, the mixture being cooled, if necessary, with ice, to prevent a rise of temperature above 50° C. (122° F.). The reaction, which at first is quite violent, is allowed to go on for from six to twelve hours, after which the mixture of acid and glycerin is decanted, the residue mixed with 100 parts of water, and, after stirring, is also decanted. The resulting sulpholeic acid is converted into *alkaline sulpholeate* by the addition of a hydroxide or carbonate of the required alkali. From this combination pure sulpholeic acid is obtained by careful decomposition with sulphuric acid, and agitation with purified benzol or ether, which leaves the acid on evaporation pure and anhydrous. (*Ph. Rund.*, 1885, p. 164.) According to A. Mueller Jacobs, when concentrated and in as pure a state as possible, the sulpholeates, as well as the free sulpho-acids themselves, mix readily and completely with a great variety of organic compounds, for instance with liquid hydrocarbons, particularly those of low boiling point, with chlorine, iodine, and bromine derivatives of the same, with ethers and alcohols, with organic sulphur compounds, such as carbon disulphide, oil of mustard, mercaptan, etc., and with all essential oils. They also dissolve varying quantities of sulphur, iodoform, solid hydrocarbons, such as naphthalene, naphthol, anthracene, and paraffin, the terpenes and camphenes. These liquid mixtures of sulpholeates and other bodies have the property of forming emulsions or even clear solutions with water. The limit of miscibility (in form of emulsion) or solubility varies considerably, and depends both on the degree of concentration of the sulpholeate serving as a menstruum, and on certain little understood properties of the substances mixed with it.

This peculiar behavior of the sulpholeates, and particularly of the sulpho-ricinoleate of alkalies, towards many otherwise insoluble or difficultly soluble substances, as well as their pronounced saponaceous character and the great readiness with which they take up and combine with liquids, is said to render them eminently suitable for various technical and medicinal uses.

The liquid alkaline salt which forms the solvent is termed *polysoap* by A. Mueller Jacobs, who believes that the sulpholeate mixtures will be found excellent solvents for substances the employment of which in a concentrated condition is accompanied by certain untoward effects, or may serve as vehicles in place of vaseline, oils, glycerin, etc., in perfumery, soap making or pharmacy. (*Am. Drug.*, 1884, p. 22.)

² *Cupri Oleas*.—Oleate of Copper is made by adding sodium oleate to a saturated solution of copper sulphate, then washing the precipitate. It is a handsome dark green, waxy solid, and is used chiefly in the treatment of ringworm.

W. A. H. Naylor communicates the following working formulas for unoffical oleates which he has found in practice to yield satisfactory products. The soap used is a genuine olive oil soap of high quality, and contains 15 per cent. of water.

Aluminum Oleate.—Dissolve 1 oz. av. pure potassium alum in 6 fl. oz. of boiling water and pour the solution, while stirring, into a solution of 2 oz. av. of soap in 10 fl. oz. of boiling water. The clotty precipitate is washed with boiling water by

The medicinal properties of the oleates are, of course, dependent upon the base, so that these preparations may be considered the equivalents of the corresponding ointments, over which, however, they have certain advantages. They are much cleaner and more elegant in appearance. They seem to be more irritating than the ointments, and, unless diluted with an equal bulk of cotton seed, olive, or other bland oil, are, when applied with friction, likely to provoke a cutaneous eruption or even pustulation. Marshall recommends that they be applied with a brush, or gently spread over the part with one finger.

OLEATUM ATROPINÆ. U. S.

OLEATE OF ATROPINE

(ōl-ē-ă'tūmăt-rō-pī'næ)

Atropinum Oleicum; Oléate d'Atropine, Fr.; Atropinoleat, G.

* "Atropine, two grammes [or 31 grains]; Alcohol, two cubic centimeters [or 32 minims]; Oleic Acid, fifty grammes [or 1 ounce av., 334 grains]; Olive Oil, a sufficient quantity, to make one hundred grammes [or 3 ounces av., 231 grains]. Triturate the Atropine in a tared mortar with the Alcohol, then add about an equal volume of the Oleic Acid, and, after warming the mortar, stir until the Alcohol has evaporated, add the remainder of the Oleic Acid, and continue stirring until the Atropine is dissolved; then add sufficient Olive Oil to make the product weigh one hundred grammes [or 3 ounces av., 231 grains]." U. S.

Oleate of atropine was introduced into the U. S. P. (8th Rev.) for the first time; alcohol

decanation, until free from sulphate, and dried over a water bath. The oleate is adhesive, of a yellowish-grey color, opaque, and weighs about 2¼ oz. av. On ignition it yields 6 per cent. of aluminum oxide (= 3.2 per cent. Al). This oleate is used in treating various skin diseases.

Bismuth Oleate.—Instead of crystallizing bismuth nitrate, as suggested by L. Wolff (see p. 820), the subnitrate may advantageously be used as follows: Dissolve 1 oz. av. of bismuth subnitrate, by the aid of heat, in 5½ fl. drachms of nitric acid, diluted with its own volume of distilled water; then dilute the solution with three times its volume of distilled water, and pour it, hot and while stirring, into a hot solution of 3 oz. av. of soap and 24 fl. oz. of water. The precipitate is washed with hot water by decantation, and dried over a water bath. The yield of dry oleate is about 3 oz. av. It has a light citron color and yields on ignition 22 per cent. of bismuth oxide (= 20 per cent. Bi).

Ferrous Oleate.—In spite of all precautions this oleate undergoes considerable oxidation during the process of its preparation, which must therefore be as expeditious as possible. Dissolve 1 oz. av. of pure ferrous sulphate in 5 fl. oz. of distilled water and pour the solution while stirring into a solution of 2 oz. av. of soap in 16 fl. oz. of water. When the precipitate produced has been sufficiently washed it should be at once strongly expressed and dried (in the unbroken state of press-cake), at a temperature not exceeding 50° C. (122° F.).

Ferrio Oleate, on the other hand, is easily and quickly made, by pouring 4 fluid oz. of solution of iron acetate, B. P., 1898, into a solution of 2¼ oz. av. of soap in 16 fl. oz. of boiling water. The washed precipitate, dried on the water bath, is of a deep red color, weighs a little over 2 oz. av., and yields 8 per cent. Fe₂O₃ (= 5.6 per cent. Fe) on ignition. It is readily soluble in fixed oils.

is used to facilitate the solution of the alkaloid, and olive oil is added to obviate the likelihood of producing a cutaneous eruption when the oleate is applied to the skin by friction; undiluted oleic acid is often irritating. It is used to obtain the local effects of atropine by innunction.

OLEATUM COCAINÆ. U. S.

OLEATE OF COCAINE

(ôl-ê-ă'tûm ô-că-î'næ)

Cocainum Oleicum; Oléate de Cocaine, *Fr.*; Cocainoleat, *G.*

* "Cocaine, five grammes [or 77 grains]; Alcohol, five cubic centimeters [or 81 minims]; Oleic Acid, fifty grammes [or 1 ounce av., 334 grains]; Olive Oil, a sufficient quantity, to make one hundred grammes [or 3 ounces av., 231 grains]. Triturate the Cocaine in a tared mortar with the Alcohol, then add about an equal volume of the Oleic Acid, and, after warming the mortar, stir until the Alcohol has evaporated, add the remainder of the Oleic Acid, and continue stirring until the Cocaine is dissolved; then add sufficient Olive Oil to make the product weigh one hundred grammes [or 3 ounces av., 231 grains]." *U. S.*

Oleate of cocaine was introduced into the U. S. P. (8th Rev.) to provide a preparation which could be applied locally. The alcohol and olive oil are used for the same reasons that they were added to oleic acid and atropine in the oleate of atropine. (See *Oleatum Atropinæ*.)

OLEATUM HYDRARGYRI. U. S. (Br.)

OLEATE OF MERCURY

(ôl-ê-ă'tûm hÿ-dră'rġÿ-ri)

"Precipitated Mercuric Oleate, formed by the interaction of mercuric chloride and sodium oleate." *Br.*

Hydrargyri Oleas, *Br.*; Mercuric Oleate; Hydrargyrum Oleicum; Oléate de Mercure, *Fr.*; Oel-saures Quecksilber, Quecksilberoleat, Mercurioleat, *G.*

* "Yellow Mercuric Oxide, in very fine powder, twenty-five grammes [or 386 grains]; Distilled Water, twenty-five cubic centimeters [or 406 minims]; Oleic Acid, a sufficient quantity, to make one hundred grammes [or 3 ounces av., 231 grains]. Triturate the Yellow Mercuric Oxide with the Distilled Water in a tared mortar; add seventy grammes [or 2 ounces av., 205 grains] of Oleic Acid, and mix thoroughly; warm the mortar to a temperature not exceeding 50° C. (122° F.), stir occasionally until the water has evaporated, then add, if necessary, Oleic Acid to make one hundred grammes [or 3 ounces av., 231 grains], and mix thoroughly. Avoid contact with metallic utensils; preserve the Oleate in tightly stoppered bottles." *U. S.*

"Mercuric Chloride, 1 ounce (Imperial) or 32 grammes; Hard Soap, powdered, 2 ounces (Imp.) or 64 grammes; Oleic Acid, 1 *℥*. drachm (Imp. meas.) or 4 cubic centimetres; Distilled Water, boiling, a sufficient quantity. Dissolve the Mercuric Chloride in ten fluid ounces (Imp. meas.) or three hundred and twenty cubic centimetres of the Distilled Water. Triturate the Oleic Acid with the Hard Soap, and dissolve the product in eleven fluid ounces (Imp. meas.) or three hundred and fifty-two cubic centimetres of the Distilled Water. Mix the solutions; boil for ten minutes; set aside for the mercuric oleate to deposit; decant the supernatant liquid; wash the precipitated oleate with hot Distilled Water until the decanted liquid affords little or no reaction for chloride, and then dry it on a water-bath." *Br.* It is "a substance of unctuous consistence, having a light greyish-yellow color, liable to darken by keeping. It has a somewhat saponaceous odor." *Br.*

This oleate is now made with 25 per cent. of mercuric oxide, an increase of 5 per cent. over that of the previous pharmacopœia. Water is used in this oleate in order to facilitate combination.

This preparation was introduced by Marshall in 1872. If made from oleic acid which has been purified from the usual contaminations (palmitic and stearic acids), it is a clear yellowish liquid of a thick consistence and having the peculiar odor of oleic acid. As usually seen, however, it is of the consistence and appearance of petrolatum, due to the presence of small quantities of mercuric palmitate and stearate. (See *Acidum Oleicum*, p. 56.) The formula of a normal oleate of mercury would be $(C_{18}H_{35}O_2)_2Hg$. For its formation we should reckon for every 25 parts of mercuric oxide from 65 to 66 parts of oleic acid. Free oleic acid is intentionally present in this U. S. preparation, which is known frequently as "25 per cent. oleate of mercury." In making this preparation, care must be exercised in the selection of the oleic acid, and to avoid exceeding the degree of heat directed in the official process; indeed, our experience has been that it keeps better if made by the cold process, *i.e.*, by simply mixing the freshly precipitated yellow oxide with the oleic acid, and allowing them to stand at ordinary temperatures until the precipitate has dissolved. The British preparation is modelled after Shoemaker's process. The precipitated mercuric oleate is difficult to free from water, and is prone to change. In time, even with the best oleic acid that can be procured, some decomposition will take place, and metallic mercury will be found at the bottom of the containing bottle. The rapidity of the change will be in proportion to the impurities in the oleic acid and the degree of heat employed. Beringer's process, by the double decomposition of potassium oleate and mercuric nitrate, is commended by Edell. (See *West. Drug.*, 1894, 85.)

Uses.—This preparation may often be substituted with advantage for mercurial ointment, which it closely resembles in its medicinal properties, except that it is more readily absorbed, and therefore more effective. It has been especially commended by Marshall in cases of *chronically inflamed joints*, and in *hordeolum*, *indurations after abscesses*, and various other forms of superficial local inflammations of a slow type; also in *sycosis*, *tinea*, *psoriasis*, *eczema*, and as a constitutional alternative in *hereditary syphilis*. For many purposes it is much improved by dissolving in every drachm of it one grain of morphine. The alkaloid itself must be used in such cases, as its salts are not soluble in oleic acid.

OLEATUM QUININÆ. U. S.

OLEATE OF QUININE

(öl-ə-ä'tüm qui-nī'næ)

Chininum Oleicum; Oléate de Quinine, *Fr.*; Chininoleat, *G.*

* "Quinine, *twenty-five grammes* [or 386 grains]; Oleic Acid, *seventy-five grammes* [or 2 ounces av., 282 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Triturate the Quinine in a warm mortar with a small quantity of the Oleic Acid to a smooth paste. Then add the remainder of the Oleic Acid, previously warmed, and stir frequently, until the Quinine is dissolved." *U. S.*

This oleate was introduced into the *U. S. P.* (8th Rev.) to provide a convenient preparation for the local application of the alkaloid quinine.

OLEATUM VERATRINÆ. U. S.

OLEATE OF VERATRINE

(öl-ə-ä'tüm vër-ə-trī'næ)

Veratrinum Oleicum; Oléate de Véatrine, *Fr.*; Oelsaures Veratrin, Veratrinoleat, *G.*

* "Veratrine, *two grammes* [or 31 grains]; Oleic Acid, *fifty grammes* [or 1 ounce av., 334 grains]; Olive Oil, a *sufficient quantity*, to make *one hundred grammes* [or 3 ounces av., 231 grains]. Triturate the Veratrine in a tared mortar with about *five cubic centimeters* [or 81 minims] of Olive Oil, and, after warming the mortar, add the Oleic Acid, and continue stirring until the Veratrine is dissolved; then add sufficient Olive Oil to make the product weigh *one hundred grammes* [or 3 ounces av., 231 grains]." *U. S.*

This preparation is simply a solution of the alkaloid in oleic acid and olive oil. (See *Oleatum Atropinæ*). It may be used instead of ointment of veratrine, but is exactly half the strength. It is well adapted for obtaining all the advantage that can be derived from an application of veratrine by innunction. (See

Veratrina.) When the veratrine is to be used as a counter-irritant, the ointment is preferable, because less favorable to the absorption of the alkaloid. The *oleate of morphine* is made in the same proportion and in the same way as is oleate of veratrine.

OLEORESINA ASPIDII. U. S. (Br.)

OLEORESIN OF ASPIDIUM

(öl-ə-ö-rës'ī-nə əs-pid'ī-i)

Extractum Filicis Liquidum, Br.; Oleoresina Filicis, *Pharm.* 1870; Liquid Extract of Male Fern, Oil of Fern; Oleum Filicis Maris; Extrait de Fougère Mâle, *Fr. Cod.*; Extractum Filicis, *P. G.*; Farnextrakt, Wurmfarnextrakt, Wurmfarnöl, *G.*; Estratto de felce maschio etero, *It.*; Extracto etero de helecho macho, *Sp.*

* "Aspidium, recently reduced to No. 40 powder, *five hundred grammes* [or 17 ounces av., 279 grains]; Acetone, a *sufficient quantity*. Introduce the Aspidium into a cylindrical glass percolator, provided with a stop-cock, and arranged with a cover and a receptacle suitable for volatile liquids. Pack the powder firmly, and percolate slowly with Acetone, added in successive portions, until the Aspidium is exhausted. Recover the greater part of the Acetone from the percolate by distillation on a water-bath, and, having transferred the residue to a dish, allow the remaining Acetone to evaporate spontaneously in a warm place. Keep the Oleoresin in a well-stoppered bottle.

NOTE.—Oleoresin of Aspidium usually deposits, on standing, a granular, crystalline substance. This should be thoroughly mixed with the liquid portion before use." *U. S.*

"Exhaust Male Fern Rhizome, in No. 20 powder, with Ether, by percolation; evaporate the Ether from the clear percolate on a water-bath or by distillation, until an oily Extract remains." *Br.*

This is the only preparation of male fern which should be used; in its making aspidium which is green in color and recently collected should be employed. It is a thick, dark green liquid, usually containing a granular deposit of *filicic acid*, which is regarded as the active ingredient and should not be separated. For a method of determining the percentage of filicic acid by Dacomo and Scoccianti, see *Ph. Centralh.*, 1896, 208. Wm. G. Greenewalt found both the liquid and the sediment effective teneicides, the sediment somewhat the more active. It has the odor of fern, and a nauseous, bitterish, somewhat acrid taste. According to Hayes, when an absolutely dry root and an anhydrous ether (containing but little alcohol) of a specific gravity below 0.728 are used, the oleoresin remains clear. Kramer states that a very active extract of male fern may be prepared by exhausting with ether the fresh juicy rhizomes collected in May or October freed from scales and cut into small pieces. The ethereal tincture should be kept in a cool place until wanted, when the necessary quantity should be converted into extract. One dose,

two to four drachms, of such an extract is said to have always produced satisfactory results. (*Ph. Cb.*, xxv. 578.) Oleoresin of male fern is sometimes found in the market containing noticeable proportions of copper, and in many cases it is colored green artificially.

Dose, from one-half to one fluidrachm (1.8 to 3.75 Ce.), administered in gelatin capsules.

OLEORESINA CAPSICI. U. S.

OLEORESIN OF CAPSICUM

(ô-le-ô-rês'-i-nâ câp-si-cî)

Oléorésine (Extrait étheré) de Capsique, *Fr.*; Spanischpfeffer-Oelharz, Aetherisches Spanischpfeffer-extrakt, *G.*

* "Capsicum, in No. 40 powder, *five hundred grammes* [or 17 ounces av., 279 grains]; Acetone, *a sufficient quantity*. Introduce the Capsicum into a cylindrical glass percolator, provided with a stop-cock, and arranged with a cover and a receptacle suitable for volatile liquids. Pack the powder firmly, and percolate slowly with Acetone, added in successive portions, until *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of percolate have been obtained. Recover the greater part of the Acetone from the percolate by distillation on a water-bath, and, having transferred the residue to a dish, allow the remaining Acetone to evaporate spontaneously in a warm place. Then pour off the liquid portion, transfer the remainder to a glass funnel provided with a pledget of cotton, and when the separated fatty matter (which is to be rejected) has been completely drained, mix the liquid portions together. Keep the Oleoresin in a well-stoppered bottle." *U. S.*

The active principle of capsicum, called *capsicin*, is very soluble in ether, and is wholly extracted in the process. Its precise nature has not been determined. (See *Capsicum*.) After the concentration of the acetone solution, a solid fatty matter separates on standing, but a portion of fixed oil probably still remains. The preparation is a very thick liquid, capable however, of being dropped, of a dark reddish-brown color, and, though opaque in mass, yet transparent in thin layers. It has not very decidedly the odor of capsicum, but to the taste is intensely pungent. W. C. Alpers found a capsicum which yielded 16 per cent. of oleoresin; the statement has been frequently made that 5 per cent. is the usual yield. (*M. R.*, 1896, 593.) It may be usefully employed to give locally stimulant properties to substances administered internally in a pilular form, in cases of *gastric insensibility* and *excessive flatulence*. One drop given three times a day has produced cystic irritation and strangury. It may be used also as a powerful rubefacient, diluted with olive oil or soap liniment.

Dose, from one-fourth to one minim (0.015 to 0.06 Ce.).

Off. Prep.—Emplastrum Capsici, *U. S.*

OLEORESINA CUBEBÆ. U. S.

OLEORESIN OF CUBE

(ô-le-ô-rês'-i-nâ cù-bê'bæ)

Extractum Cubebæ Æthereum; Oléorésine de Cubèbe, *Fr.*; Extractum Cubebæ, *P. G.*; Aetherisches Kubebenextrakt, *G.*

* "Cubeb, in No. 30 powder, *five hundred grammes* [or 17 ounces av., 279 grains]; Alcohol, *a sufficient quantity*. Introduce the Cubeb into a cylindrical glass percolator, pack the powder firmly, and percolate slowly with Alcohol, added in successive portions, until the Cubeb is exhausted. Recover the greater part of the Alcohol from the percolate by distillation on a water-bath, and, having transferred the residue to a dish, allow the remaining Alcohol to evaporate, with constant stirring, in a warm place. Keep the Oleoresin in a well-stoppered bottle.

NOTE.—Oleoresin of Cubeb deposits, after standing for some time, a waxy and crystalline matter, which should be rejected, the liquid portion only being used." *U. S.*

A change was made in the menstruum for this oleoresin in the *U. S. P.* (8th Rev.) alcohol now being used instead of ether or acetone. The use of alcohol was suggested by E. R. Squibb. This oleoresin consists mainly of the volatile oil and resin, with a portion of the cubebin and waxy matter of the cubeb. The consistence differs according to the character of the cubeb employed, its degree of fluidity being proportionate to the amount of volatile oil contained in the medicine. The color is usually blackish brown, with more or less of a greenish hue, according to the quantity of chlorophyll present, which varies with the character of the cubeb, and with that of the menstruum, pure ether extracting the green coloring matter preferably, while alcohol extracts the brown; unripe fruit or berries yield more chlorophyll than ripe fruit. Cubeb yields from one-eighth to one-fifth of its weight of the oleoresin. The preparation deposits waxy matter and crystals of cubebin on standing, which should be separated; its efficacy is not impaired on this account. It was first introduced into use by Procter. (*A. J. P.*, xviii. 168.)

From carefully conducted experiments by F. V. Heydenreich, it would appear that, of the various constituents of cubeb contained in the official oleoresin, the cubebin has no perceptible effect in the dose of the medicine ordinarily given, that the volatile oil is simply stimulant and carminative, and, finally, that the soft resin has all the diuretic properties of the cubeb. Of the last-mentioned ingredient, twenty grains (1.3 Gm.) given every two hours until five doses were taken considerably increased the secretion of urine, producing at the same time a slight burning sensation in the passage, which ceased with the diuretic action. Pushed beyond this amount,

it occasioned severe irritation of the urinary passages, with some fever. (*Ibid.* Jan. 1868, p. 42.)

This oleoresin, as it occurs in the market, often has a thin consistence. In one specimen three-eighths of its weight were lost in a short time by the spontaneous evaporation of the ether improperly left in the product.

Dose, from five to ten minims (0.3 to 0.6 Cc.), given suspended in water, or mixed with powdered sugar.

Off. Prep.—Trochisci Cubebæ, U. S.

OLEORESINA LUPULINI. U. S.

OLEORESIN OF LUPULIN

(ō-lē-ō-rēs'ī-nā lū-pū-lī-ni)

Oleoresina Lupulinæ, *Pharm.* 1870; Extractum Lupulini Æthereum; Oléorésine de Lupuline, *Fr.*; Aetherisches Lupulinextrakt, *G.*

* "Lupulin, five hundred grammes [or 17 ounces av., 279 grains]; Acetone, a sufficient quantity. Introduce the Lupulin into a cylindrical glass percolator, provided with a stop-cock, and arranged with a cover and a receptacle suitable for volatile liquids. Press the powder very lightly, and percolate slowly with Acetone, added in successive portions, until the Lupulin is exhausted. Recover the greater part of the Acetone from the percolate by distillation on a water-bath, and, having transferred the residue to a dish, allow the remaining Acetone to evaporate spontaneously in a warm place. Keep the Oleoresin in a well-stoppered bottle." U. S.

Lupulin yields its volatile oil and resin, as well as any other active principle it may contain, to acetone, and the resulting oleoresin constitutes about three-eighths, or somewhat less than one-half, of the original drug. It is of a very thick, semi-fluid consistence, so thick, indeed, that it cannot be conveniently administered by drops. Its color is almost black in mass, but a rich reddish brown in thin layers. It has the odor and taste of lupulin, and possesses all its medicinal properties. It may be most conveniently administered in the form of pill, made with powdered licorice root, or other proper excipient.

Dose, from one to five minims (0.06 to 0.3 Cc.).

OLEORESINA PIPERIS. U. S.

OLEORESIN OF PEPPER

(ō-lē-ō-rēs'ī-nā pīp'ē-ris)

Extractum Piperis Fluidum, U. S. 1850; Fluid Extract of Black Pepper; Oléorésine de Poivre noir, *Fr.*; Aetherisches Pfefferextrakt, *G.*

* "Pepper, in No. 40 powder, five hundred grammes [or 17 ounces av., 279 grains]; Acetone, a sufficient quantity. Introduce the Pepper into a cylindrical glass percolator, provided with a stop-cock, and arranged with

a cover and a receptacle for volatile liquids. Pack the powder firmly, and percolate slowly with Acetone, added in successive portions, until the Pepper is exhausted. Recover the greater part of the Acetone from the percolate by distillation on a water-bath, and, having transferred the residue to a dish, set this aside in a warm place until the remaining Acetone has evaporated, and the deposition of crystals of piperin has ceased. Lastly, separate the Oleoresin from the piperin by straining through purified cotton. Keep the Oleoresin in a well-stoppered bottle." U. S.

A substance has long been in use under the name of *oil of black pepper*, consisting mainly of the volatile oil, fixed oil, and resin of the pepper, and belonging, therefore, to the oleoresins. As usually found, it is almost black and of a thickish consistence, and is a residue of the process for preparing piperin. The official oleoresin made with acetone has the same general character, but is more fluid and of more uniform strength, and should, therefore, be preferred. It contains almost all the volatile oil and acrid resin of black pepper, with little of the piperin, and, as the last-mentioned principle, when quite pure, is of doubtful efficacy, the extract may be considered as representing the virtues of the fruit. The color is greener than that of the common oil of black pepper, and not so dark, owing to the fact that the solvent dissolves the green more readily than the brown coloring matter. A pound of black pepper yields about six drachms of the oleoresin.

Dose, from one-fourth to one minim (0.015 to 0.06 Cc.), in emulsion or pill.

OLEORESINA ZINGIBERIS. U. S.

OLEORESIN OF GINGER

(ō-lē-ō-rēs'ī-nā zīn-gīb'ē-ris)

Extractum Zingiberis Æthereum; Oléorésine (Pipérólde) de Gingembre, *Fr.*; Zingiberin, Aetherisches Ingwerextrakt, *G.*

* "Ginger, in No. 60 powder, five hundred grammes [or 17 ounces av., 279 grains]; Acetone, a sufficient quantity. Introduce the Ginger into a cylindrical glass percolator, provided with a stop-cock, and arranged with a cover and a receptacle suitable for volatile liquids. Pack the powder firmly, and percolate slowly with Acetone, added in successive portions, until the Ginger is exhausted. Recover the greater part of the Acetone from the percolate by distillation on a water-bath, and, having transferred the residue to a dish, allow the remaining Acetone to evaporate spontaneously in a warm place. Keep the Oleoresin in a well-stoppered bottle." U. S.

In the U. S. formula of 1870 for this preparation alcohol was used in connection with ether, on the score of economy; it was added in order to displace the ether and thus save an unnecessary expenditure of the more

costly fluid. A little of the alcohol mixed with the ether at their surface of contact. In the present process both ether and alcohol have been replaced by the new solvent, acetone. The whole of the virtues of the root are extracted in this preparation, as the residuary ginger is nearly or quite tasteless. The oleoresin constitutes about 5 per cent. of the dried root. It is the *piperoid of ginger* of Beral. (Soubeiran's *Traité de Pharm.*, i. 371.) It is a clear, dark-brown liquid, of a thick consistence (though capable of being dropped), with the flavor of ginger, and very pungent.

Dose, one-half to one minim (0.03 to 0.06 Cc.), well diluted.

OLEORESINÆ.

OLEORESINS

(ō-lē-ō-rēs'ī-næ)

Oléo-résines, Extraits étherés, *Fr.*; Oelharze, Aetherische Extrakte, *G.*

The oleoresins, as a class of preparations, were introduced into the U. S. Pharmacopœia at the revision of 1860, having been previously classed with the Fluidextracts. Their peculiarity is that they consist of principles which, when extracted by means of ether, alcohol, or acetone, retain a liquid or semi-liquid state upon the evaporation of the menstruum, and at the same time have the property of self-preservation, differing from the fluidextracts in not having a definite relation of strength to the drug. They consist chiefly, as their name implies, of oil, either fixed or volatile, holding resin and sometimes other active matter in solution. Their preparation is very simple, consisting in the exhaustion of the medicine employed with acetone or alcohol by means of percolation, and the subsequent evaporation of the menstruum. In consequence of the great volatility of the solvent, it may in great measure be recovered by distillation, thus very materially diminishing the costliness of the process. It is proper not to continue the heat necessary for the distillation until the whole of the solvent is driven over, lest, towards the close, a portion of the volatile matters also should pass, and the strength of the oleoresin be impaired. Hence in every instance the last portions of the menstruum are allowed to separate by spontaneous evaporation. Petroleum benzin has been proposed as a substitute for other solvents in these preparations, but should not be permitted to supersede them until officially sanctioned. Acetone has replaced ether in most of the formulas of the U. S. P. (8th Rev.). Oleoresin of cubeb is made with alcohol.

OLEUM ADIPIS. U. S.

LARD OIL

(ō'lē-ūm ād'ī-pīs)

"A fixed oil expressed from lard at a low temperature." *U. S.*

Huile de Graisse, *Fr.*; Schmalzöl, Specköl, *G.*

Lard oil is made in large quantities in this country by exposing lard to low temperatures and then subjecting it to very powerful pressure. In this way the stearin of the lard is separated from the olein, the latter oozing out from the presses in the form of a yellowish-white oil, while the stearin is thrown into the market in hard cakes, and is largely used in making soap. (See *Adeps.*) The exportation of lard from the United States for the year ending June 30, 1904, amounted to 561,302,643 pounds, valued at \$46,347,520, and that of lard compounds and substitutes to 53,603,545 pounds, valued at \$3,581,813. (*U. S. Treasury Statistical Reports.*)

Properties.—Lard oil is "a colorless or pale yellow, oily liquid, having a peculiar odor and a bland taste. Specific gravity: 0.905 to 0.915 at 25° C. (77° F.). At a temperature a little below 10° C. (50° F.), it usually commences to deposit a white, granular fat, and at or near 0° C. (32° F.), it forms a solid white mass. Lard oil is almost insoluble in cold alcohol and only slightly soluble in boiling alcohol; easily soluble in ether, chloroform, benzene, and carbon disulphide. If 5 Cc. of the Oil be thoroughly shaken in a test-tube with 5 Cc. of an alcoholic solution of silver nitrate (made by dissolving 0.1 Gm. of silver nitrate in 10 Cc. of alcohol, and adding 2 drops of nitric acid), and the mixture heated for about five minutes on a water-bath, the Oil should remain nearly or quite colorless, not acquiring a reddish or brown color (absence of more than about 5 percent. of *cotton seed oil*). The Oil should be completely saponifiable with alcoholic potassium hydroxide T.S. and the resulting soap should be completely soluble in water, without separation of an oily layer (absence of *mineral oils*). If 2 Cc. of Lard Oil be mixed in a test-tube with 2 Cc. of equal volumes of amyl alcohol and carbon disulphide containing 1 percent. of sulphur in solution, and the test-tube be immersed to one-third or one-half its depth in boiling salt water, no reddish color should develop in from ten to fifteen minutes (absence of *cotton seed oil* or of *certain other fats*). Lard Oil saponified by alcoholic potassium hydroxide T.S. should show a saponification value of 195 to 197 (see PART III, Test No. 99). If 0.3 Gm. of Lard Oil be dissolved in 10 Cc. of chloroform, in a 250 Cc. bottle or flask, and 25 Cc. of a mixture of equal volumes of alcoholic iodine T.S. and alcoholic mercuric chloride T.S. added, and if, after standing for four hours protected from the light, 20 Cc. of potassium iodide T.S. be added, and the mixture diluted with 50 Cc. of water, on titrating the excess of iodine with tenth-normal sodium thiosulphate V.S., an iodine value of not less than 56 nor more than 74 should be obtained (see PART III, Test No. 51)." *U. S.* It is not pure olein, but contains varying proportions of stearin, and is sometimes adulterated with paraffin oil. It was introduced into the U. S. P. 1880 for the

purpose of rendering the ointment of mercuric nitrate softer and smoother in consistence, but it was not retained in the process of the U. S. P. (8th Rev.) mainly owing to the difficulty of obtaining it of sufficient purity in commerce.

Uses.—Lard oil is a bland, fatty liquid, destitute of active medicinal properties, and is official solely for pharmaceutical purposes.

OLEUM ÆTHEREUM. U. S.

ETHEREAL OIL

(ô'le-üm æ-thê-rê-üm)

"A volatile liquid consisting of equal volumes of heavy oil of wine and ether." U. S.

Oleum Vini; Heavy Oil of Wine; Huile d'Ether, Huile de Vin pesante, Huile volatile étherée, *Fr.*; Schweres Weindöl, *G.*

* "Alcohol, one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]; Sulphuric Acid, one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]; Distilled Water, twenty-five cubic centimeters [or 406 minims]; Ether, a sufficient quantity. Add the Sulphuric Acid slowly to the Alcohol, mix them thoroughly and allow the mixture to stand, in a closed flask, for twenty-four hours, or until the liquid is clear; then pour the clear liquid into a tubulated retort of such capacity that the mixture shall nearly fill it. Insert a thermometer through the tubulure, so that the bulb shall be deeply immersed in the liquid, and, having connected the retort with a well-cooled condenser, and also having connected with the receiver a bent glass tube for conducting the uncondensed gases into water, distil, by means of a sand-bath, at a temperature between 150° and 160° C. (302° and 320° F.), until oily drops cease to come over, or until a black froth, which forms on the surface, begins to rise in the retort. Separate the yellow, ethereal liquid from the distillate, and expose it to the air for twenty-four hours, in a shallow dish. Then transfer it to a wet filter, and, when the aqueous portion has drained off, wash the oil which is left on the filter with the Distilled Water, which should be as cold as possible. When this also has drained off, transfer the oil to a graduated measure, and add to it an equal volume of Ether. Keep the product in small, glass-stoppered vials, in a cool place." U. S.

In the consolidation of the British Pharmacopœias this valuable remedy was omitted, partly on account of the uncertainty as to its special antispasmodic virtues, partly from its expensiveness when properly made and its liability to spontaneous change, and partly, moreover, because not only is it often adulterated, but other compounds are substituted for it. The Committee of Revision of the U. S. P. (8th Rev.) decided to retain it.

The object of allowing the mixture of acid and alcohol to stand is to allow the lead sulphate which is usually present in commercial

sulphuric acid to deposit, for, according to E. R. Squibb, its presence in the retort causes the mixture to froth over, and this necessitates a suspension of the process so much sooner as greatly to lessen the amount of product the materials are capable of affording. The increase of oil resulting from this simple modification of the process is said to be one-third. The temperature has been slightly decreased. By wetting the filter, the oil is prevented from passing along with the water. Finally, the oil is now ordered to be diluted with an equal measure of stronger ether, as this has been found to be of great value in aiding in its preservation.

When alcohol is distilled with a large excess of sulphuric acid, there are formed towards the close of the distillation sulphurous acid, heavy oil of wine, olefiant gas, and resinocarbonaceous matter. The product of the distillation is generally in two layers, one consisting of water holding sulphurous acid in solution, and the other, of ether containing the heavy oil of wine. According to the experience of Squibb, the sp. gr. of these two layers is so nearly equal that sometimes one and sometimes the other is uppermost, so that the direction in the old formula to separate the supernatant liquor is incorrect, and has been superseded by the present, to separate the yellow ethereal liquid,—the color and other sensible properties being considered sufficiently distinctive. After separation, the liquid is exposed for twenty-four hours to the air, in order to dissipate the ether by evaporation, and the oil which is left is washed with water, in order to deprive it of all traces of sulphuric acid.

The nature and mode of formation of heavy oil of wine are generally believed to be the following. It has been explained in a preceding article that, in the early stages of the distillation of a mixture of sulphuric acid and alcohol, sulphovinic acid, $C_2H_5HSO_4$, is formed. During its progress this is decomposed so as to yield ether. When, however, the alcohol is distilled with a large excess of sulphuric acid, the sulphovinic acid is decomposed so as to form a small quantity of the heavy oil of wine. This is a mixture of ethyl sulphate, $(C_2H_5)_2SO_4$, ethyl sulphite, $(C_2H_5)_2SO_3$ (the sulphurous acid having been formed by reduction of sulphuric acid, as it always is when ethylene is formed from alcohol), with polymeric forms of ethylene, C_2H_4 . Two of these forms are known: *etherin*, a solid fusing at 110° C. and boiling at 260° C., and *etherol*, a liquid. The latter is by some considered to have the formula C_6H_8 or $(C_2H_4)_3$, and mixed with the former constitutes the *light oil of wine*, which is produced when the heavy oil is heated with water and alkaline solutions. In this case sulphovinic acid is reproduced, and the separated *etherol* floats on the surface as an oily substance. *Light oil of wine*, as thus obtained, is a pale-yellow oil. As ordi-

narly procured in the process for preparing ether, it contains a portion of that substance, admixed, according to Hartwig (*J. Pr. Chem.* [2], 23, 449), with ketones like ethyl-amyl ketone and methyl-hexyl ketone and mixed ethers like ethyl-amyl ether. When the pure light oil of wine is kept, it deposits a stearopten (the *etherin* mentioned above) called concrete oil of wine, or oil of wine camphor; after which the oil is changed, and takes the name of etherol. *Etherol* is a pale yellow oily liquid, having an aromatic odor. Its sp. gr. is 0.921, boiling point 280° C. (536° F.), and freezing point—35° C. (—31° F.). It communicates a greasy stain to paper. *Concrete oil of wine*, or *etherin*, crystallizes in long, transparent, brilliant, tasteless prisms, soluble in alcohol and ether, insoluble in water, and having the sp. gr. 0.980. Squibb takes a different view of the composition of ethereal oil, and believes it, instead of a sulphate or a mixture of sulphate and sulphite, to be a sulphovinate of a hydrocarbon radical; and for this reason, that it fails, especially when pure and recent, to give any of the characteristic reactions of sulphuric acid or the sulphates. (*A. J. P.*, 1861.)¹

Properties.—Ethereal oil is officially described as follows: "A transparent, nearly colorless, volatile liquid, of a peculiar, aromatic, ethereal odor, and a pungent, refreshing, bitter taste; neutral to dry litmus paper. Specific gravity: 0.905 at 25° C. (77° F.)." *U. S.* The undiluted ethereal oil (*heavy oil of wine*) is a yellowish neutral liquid, possessing an oleaginous consistence, a penetrating aromatic odor, and a rather sharp and bitter taste. It boils at 280° C. (536° F.). Its sp. gr. is, according to the *U. S. P.* 1850, 1.096; according to the London College, after Hennell's results, 1.05. The density obtained by Squibb, by following the old formula of the *U. S. Pharm.* 1850 exactly, was 1.129. By Dumas and Sérullas its density is stated to be as high as 1.133, which is probably the more correct number for the *pure oil*. When dropped into water it sinks, assuming the form of a globule. It dissolves sparingly in cold water, moderately in hot water, and readily in alcohol and ether. It is devoid of acid reaction, the sulphuric and sulphurous acids

present in it being in the form of neutral salts. The sulphuric acid present is not precipitated by the usual reagents for this acid, because sulphovinic acid is formed, and all the sulphovinates are soluble in water. The *U. S.* ethereal oil of the present Pharmacopœia is the proper oil diluted with an equal volume of stronger ether. This gives it an ethereal odor in addition to that characteristic of the pure oil, and considerably reduces its sp. gr., which is now stated at 0.905 at 25° C. (77° F.). The process by which the official oil of wine is formed yields but a small product, being, according to the Pharmacopœia of 1870, only about six fluidrachms, or somewhat more than a fortieth, by measure, of the alcohol employed.

In the official ethereal oil, the heavy oil of wine is not only diluted with an equal measure of ether, but is mixed also with variable proportions of free light oil of wine. This fact accounts for the different densities assigned to the heavy oil. The heavy oil undiluted is liable to spontaneous change by time, not only being rendered brown, but also being chemically altered so as to separate into two layers. But this tendency is in great measure obviated, in the official ethereal oil, by the preservative influence of the ether. It may be kept long without other appreciable change than the acquisition of a brown hue, which does not interfere with its medicinal virtues. It should not, when tested by dry litmus paper, evince the presence of free acid.

Uses.—H. A. Hare has found that the heavy oil of wine produces in mammals a rise in the arterial pressure and pulse rate, followed after sufficient doses, by a fall. The rise in the pressure was the result of a stimulant influence upon the vasomotor centre, while the fall of the pressure appeared to be due to a widening out of the blood paths by a direct paralysis of the coats of the vessels. Hare also found that very large doses paralyze the heart by a direct action on the muscle, but he did not determine the exact influence of small doses. The toxic properties of the heavy oil of wine were shown to be very feeble, and the research seems to prove that the small quantity of the heavy oil of wine contained in Hoffmann's anodyne cannot exert a very pronounced influence upon the human system. It probably has, however, a slight stimulative, calmative effect, since clinical experience indicates that compound spirit of ether is a more persistent and powerful antispasmodic and nerve stimulant than is an equivalent amount of ether and alcohol. The article sold in commerce as heavy oil of wine is too often a mixture of alcohol and ether containing but a trace of the oil. It is used only for the preparation of compound spirit of ether; there can be no justification of the action of the chemist in furnishing a fraudulent article.

Off. Prep.—*Spiritus Ætheris Compositus*, *U. S.*

¹ Valuable papers have been contributed by C. Lewis Diehl and John M. Maisch on this official preparation, the former in *Proc. A. Ph. A.*, 1864, the latter in *A. J. P.*, 1865, p. 160, to which we refer those especially interested in its manufacture. In Diehl's paper suggestions are made in reference to the mode of reheating so as properly to regulate the temperature. An important fact was stated by Maisch, that the ethereal oil, in contact with water, undergoes a decomposition into light oil of wine and sulphovinic acid, rapidly and completely if the water is hot or if the solution of an alkali or of an alkaline carbonate is used, and more slowly with cold water. Hence the inference that the washing of the ethereal oil, directed at the close of the *U. S.* process, should be completed as rapidly as possible. Care should be taken to protect the oil from the action of light. See a paper by I. W. Brandel in *Proc. A. Ph. A.*, 1903, 263; Kebler, *Am. Drug.*, 1900, 33; Scoville, *Am. Drug.*, 65.

OLEUM AMYGDALÆ AMARÆ. U. S.

OIL OF BITTER ALMOND

(ô'le-ûm a-mÿg'da-læ a-mă'ræ)

"A volatile oil obtained from Bitter Almond and other seeds containing amygdalin, yielding, when assayed as directed below, not less than 85 percent. of benzaldehyde, and not less than 2 percent. nor more than 4 percent. of hydrocyanic acid. It should be kept in small, well-stoppered, completely filled, amber-colored bottles, protected from light and air." U. S.

Oleum Amygdalarum (Amararum) Æthereum: Oleum Amygdalæ Volatile: Volatile Oil of Almond; Huile volatile d'Amande amère, *Fr.* *Cod.*; Essence d'Amandes amères, *Fr.*; Bittermandelöl, *G.*; Esencia de almendras amargas, *Sp.*

When bitter almonds are expressed, they yield a bland fixed oil, and the residuary cake, reduced to powder by grinding, and submitted to distillation with water, yields a volatile oleaginous product, commonly called oil of bitter almond. This does not pre-exist in the almond, but is produced by the action of water upon the amygdalin contained in it, through the intervention of another constituent, denominated emulsin (see *Amygdala Amara*), according to the reaction:

It is obtained also by the distillation of the leaves of the cherry-laurel, and of various products of the genera *Amygdalus*, *Cerasus*, *Prunus*, etc. Whipple obtained, upon an average, from the ground bitter almond cake, 1.35 per cent. of the oil. (*P. J.*, x. 297.) Pettenkofer has ascertained that the product is greater if the cake be macerated in water for forty-eight hours before being submitted to distillation. (*J. P. C.*, Mai, 1862, p. 432.) It is sometimes produced in France from peach kernels.

Oil of bitter almond has a yellowish color, a bitter, acrid, burning taste, and the odor of the kernels in a high degree. It is heavier than water, soluble in alcohol and ether, according to Flüchiger soluble in 300 parts of hot or cold water, and deposits, upon standing, a white crystalline substance consisting chiefly of benzoic acid. It is officially described as "a clear, colorless or yellow, thin, and strongly refractive liquid, having a peculiar aromatic odor, and a bitter and burning taste. Specific gravity: 1.045 to 1.060 at 25° C. (77° F.). Boiling point: about 180° C. (356° F.). Optically inactive. Soluble in 300 parts of water at 25° C. (77° F.), in alcohol or ether in all proportions, and in an equal volume of 70 percent. alcohol; soluble in nitric acid at ordinary temperatures without the evolution of nitrous vapors. In the fresh state the Oil is neutral to litmus paper, but when kept for some time it acquires an acid reaction, due to the formation of benzoic acid, which, when isolated and

purified, should correspond to the tests given under *Acidum Benzoicum*. Oil of Bitter Almond containing crystals of benzoic acid should not be dispensed. If 10 drops of the Oil, dissolved in a little alcohol, be shaken with a few drops of sodium hydroxide T.S. also with 2 drops of ferrous sulphate T.S. and 2 drops of ferric chloride T.S., then warmed, and finally mixed with a slight excess of hydrochloric acid, a blue precipitate will be produced (presence of *hydrocyanic acid*). If the looped end of a piece of clean copper wire be held in a non-luminous flame until it ceases to give a green color, then cooled, and the loop dipped into Oil of Bitter Almond, ignited and held so that the liquid burns outside of the flame, then if the loop be slowly brought into contact with the lower outer edge of the flame, no green tinge should be discernible (absence of *chlorinated products*). If a small strip of filter paper, folded in the form of a taper and saturated with Oil of Bitter Almond, be placed in a small porcelain dish, and a clean beaker, moistened on the inner surface with distilled water, be inverted over the small dish immediately after igniting the taper, a part of the products of combustion will be absorbed by the water; if the beaker be then rinsed with a little distilled water and the liquid filtered, the filtrate should yield no turbidity upon the addition of a few drops of silver nitrate T.S., or if a slight turbidity appears, it should entirely disappear upon boiling the liquid (absence of *artificial oils* containing *chlorinated products*)." U. S. Besides the peculiar volatile oil, it contains also hydrocyanic acid, with a small proportion of benzoic acid (produced by oxidation of the aldehyde when liberated), and of a concrete principle called *benzoin*, $\text{C}_{14}\text{H}_{12}\text{O}_2$. It may be obtained pure by agitating it strongly with calcium hydroxide and a solution of ferrous chloride, submitting the mixture to distillation, and drying the oil which comes over by digestion with calcium chloride. George Whipple states that if crude oil be redistilled into a solution of silver nitrate, and again distilled from a fresh solution of the same salt, it is obtained entirely free from hydrocyanic acid, which reacts with the silver and remains behind as silver cyanide. (See *A. J. P.*, xxvi. 348.) Thus purified, it is colorless, but still retains its peculiar odor, with a burning, aromatic taste, and is destitute of those poisonous properties of the crude oil which are dependent on hydrocyanic acid. The odor of the oil of bitter almond has been erroneously ascribed to that acid, which, on examination, will be found to have a different and more feeble odor. Like most other volatile oils, this may produce deleterious effects if taken very largely. Hippuric acid is found in the urine of animals to which the oil has been given freely. The sp. gr. of the crude oil varies from 1.052 to 1.082, and is said to be greater when the oil is distilled from salt water than when distilled by the ordinary mode. That

of the purified oil is 1.060, and its boiling point 180° C. (356° F.). It is *benzoic aldehyde*, $\text{C}_6\text{H}_5\text{COH}$, which may also be produced by the action of oxidizing agents upon *benzyl alcohol*, $\text{C}_6\text{H}_5\text{CH}_2\text{OH}$, and yields itself, when oxidized, *benzoic acid*, $\text{C}_6\text{H}_5\text{COOH}$. The benzoic acid which the oil of bitter almond deposits on standing does not pre-exist in it, but results from the absorption of oxygen, as just stated. The concrete substance above referred to by the name of *benzoin* is polymeric with the oil, crystallizable in colorless shining prisms, without odor or taste, fusible at 248° F., and volatilizable unchanged at a higher temperature. It is formed abundantly in the original impure oil by the reaction of alkalies, but cannot be produced in it when deprived of hydrocyanic acid.¹ The 8th Revision of the U. S. P. provides for an assay for benzaldehyde and also one for hydrocyanic acid, see page 41.

Benzoic aldehyde is now made from toluene, C_7H_8 . (See *Benzaldehydum*, page 229.) By the action of chlorine upon the hot hydrocarbon, benzyl chloride, $\text{C}_6\text{H}_5\text{CH}_2\text{Cl}$, results, and this yields benzoic aldehyde on distillation with lead nitrate and water in an atmosphere of carbon dioxide gas. More generally, however, *benzal chloride*, $\text{C}_6\text{H}_5\text{CHCl}_2$, is taken, as this, when heated under pressure with water or sulphuric acid, readily yields the benzaldehyde. The product is purified by conversion into the acid sulphite compound. Lippmann and Hawliczek have made exhaustive researches on the identity of the artificial with the natural oil of bitter almond, and have found the two oils absolutely identical, physically as well as chemically. At the present time *benzaldehyde*, or synthetic oil of bitter almond, is very largely used, its chief advantages being uniformity of composition and absence of hydrocyanic acid. To prevent the formation of benzoic acid in oil of bitter almond, Schimmel & Co. recommend the addition of 10 per cent. of alcohol to the oil.

Zeller mentions, as characteristics of the official oil by which its genuineness and purity may be known, its peculiar odor and high specific gravity,² its ready solubility in sulphuric acid, with the production of a reddish-brown color, but without visible decomposition, the slow action of nitric acid, the slow and partial solution of iodine without further reaction, the want of action of potassium chromate upon it, and the production of crystals when it is dissolved in an alcoholic solution of potassium hydroxide. (See *P. J.*, ix. 575.) Redwood states that a very small proportion of alcohol may be detected in the oil by the effervescence,

with disengagement of nitrous vapors, which ensues when the oil thus contaminated is mixed with an equal volume of nitric acid of the sp. gr. 1.5. With pure oil no other effect is obvious than a slight change of color. (*Ibid.*, xi. 486.) If sulphuric acid produce with the oil a bright-red instead of a brownish-red color, the oil has probably been distilled with salt water, in which case it is prone, according to Ferris, to deposit a blood-red substance, occasionally complained of by druggists. (*Ibid.*, 565.)

Wm. A. Tilden has found that the introduction of a little fused calcium chloride into purified oil of bitter almond contributes to its preservation, probably by the absorption of the last traces of water contained in it. Of two specimens of the oil, which had been set aside for two years, one without addition, the other containing a fragment of the fused chloride, the former was found filled with crystals of benzoic acid, and the latter was perfectly free from crystalline deposit and quite fluid. (*P. J.*, 2d ser., viii. 325, Dec. 1866.)

J. M. Maisch proposed the following mode of detecting nitrobenzene in adulterated oil of bitter almond. Dissolve half a drachm of the suspected oil in two or three drachms of alcohol, add fifteen grains of pure fused potassium hydroxide, heat for a few minutes so as to dissolve the potassium hydroxide, reduce the liquid to one-third, and then set it aside to cool. If the oil be pure, it will remain liquid, while if nitrobenzene be present, there will, after cooling, be a sediment of azoxybenzene indicating adulteration. (*A. J. P.*, 1857, 544.) R. Wagner proposes the sp. gr. of the two oils as a test,—that of oil of bitter almond being 1.060 to 1.070 at 15° C., while that of nitrobenzene is from 1.18 to 1.201, and a mixture will have a higher sp. gr. than the pure oil. This would lead to the suspicion of the presence of nitrobenzene, which may then be separated by agitation with sodium bisulphite. The almond oil will dissolve, while the nitrobenzene will float on the surface. (*J. P. C.*, Mai, 1868, 399.) The most reliable test is undoubtedly to add zinc dust and diluted acid, whereby any nitrobenzene is reduced to aniline, which can then be detected by the violet color produced when sodium hypochlorite or potassium dichromate is added. H. Hager's plan is as follows. After the addition of 10 drops of the pure oil to 10 Cc. of 45 per cent. alcohol, or to a mixture of 5 Cc. of 90 per cent. alcohol and 5 Cc. of water, on closing the test tube with the finger and turning it twice upside down, the oil dissolves to a clear solution. If nitrobenzene, even as little as 1 per cent., be present, the oil of bitter almond will dissolve at once, but the nitrobenzene will separate, clouding the liquid at first, but soon collecting in very minute but easily recognizable droplets which float about in the liquid. After standing for awhile, these droplets unite to larger drops, when they become still more evident to the eye. The temperature of the

¹ Nitrobenzol, Nitrobenzene, or Artificial Oil of Bitter Almond.—This substance, which was discovered by Mitscherlich, is treated of in PART II.

² Schimmel & Co. (*Semi-Annual Report*, April, 1893) state that an oil of high specific gravity should be carefully examined for benzo-nitrile, $\text{C}_6\text{H}_5\text{CN}$, which may form by condensation from benzaldehyde and hydrocyanic acid, and when distilled even *in vacuo* will decompose into the same components.

alcohol must not exceed 16° C. (60.8° F.); it is best to keep it between 10° and 15° C. (50° and 59° F.). Any sample of oil of bitter almond which dissolves on very gentle agitation at once to a clear liquid in 20 times its volume of 45 per cent. alcohol does not contain any nitrobenzene, since only traces of the latter are dissolved by that solvent. Small quantities of nitrobenzene present (up to 3 per cent.) disappear after the mixture stands for some time, but they are always the cause of the milkiness or cloudiness of the solution at the moment of preparation. A short cloudiness even occurs with as small a quantity as $\frac{1}{2}$ per cent. Since most other essential oils yield a cloudy solution with 45 per cent. alcohol, this test may also indicate the presence of foreign essential oils.

Hager's test may also be used quantitatively for the estimation of the amount of nitrobenzene present. Oil of bitter almond requires for solution 16 to 17 times its volume of 45 per cent. alcohol. 2 Cc. of the oil are agitated with 34 Cc. of the 45 per cent. alcohol, and the mixture set aside. After the lapse of a day, the nitrobenzene (all but a trace which remains in solution) will be found collected at the bottom. An important indication of the presence of a sophistication is the cloudiness produced at the first moment. (*N. R.*, Oct. 1880.)

Assay for Benzaldehyde.—"The method to be employed is identical with that given for Benzaldehyde, on page 229, using *twelve drops* of Oil of Bitter Almond." *U. S.*

Assay for Hydrocyanic Acid.—"Mix, in a 100 Cc. flask, 1 Gm. of the Oil of Bitter Almond to be tested, with sufficient water and freshly precipitated magnesium hydroxide (free from chlorides) to make an opaque mixture of about 50 Cc. Add to this 2 or 3 drops of potassium chromate T.S., and then from a burette add tenth-normal silver nitrate V.S. until a red tint is produced which does not again disappear by shaking; not less than 7.5 Cc. nor more than 14.9 Cc. of tenth-normal silver nitrate V.S. should be required, each Cc. corresponding to 0.002684 Gm. of hydrocyanic acid." *U. S.*

Uses.—The unpurified volatile oil of bitter almond, which is the product directed by the Pharmacopœia, acts physiologically like hydrocyanic acid. Death is said to have occurred in a man ten minutes after taking two drachms (7.5 Cc.) of the oil. It might be substituted with advantage for medicinal hydrocyanic acid, if it always contained a uniform percentage of the acid, as the acid contained in the oil is much less liable to decomposition, remaining for several years unaltered, provided the oil be preserved in well-stoppered bottles. According to Schrader, 100 parts of the oil contain sufficient acid for the production of 22.5 parts of Prussian blue, but the proportion is not constant, varying, according to Groves, from 8 to 12.5 per cent., the *U. S.* official standard is, however, not less than 2 per cent. and not

more than 4 per cent. It has been employed externally, dissolved in water in the proportion of one minim (0.06 Cc.) to a fluidounce (30 Cc.), in *prurigo senilis* and other cases of troublesome *itching*. To facilitate the solution in water, the oil may be previously dissolved in spirit. Oil of bitter almond is sometimes used to conceal the taste of cod liver oil and of castor oil.

Dose, one-fourth to one minim (0.015 to 0.06 Cc.).

OLEUM AMYGDALÆ EXPRESSUM. *U. S. (Br.)*

EXPRESSED OIL OF ALMOND

(6'le-üm a-mÿg'da-læ ex-prës'süm)

"A fixed oil expressed from Bitter or Sweet Almond. It should be kept in well-stoppered containers, in a cool place." *U. S.* "The oil expressed from the Bitter or Sweet Almond." *Br.*

Oleum Amygdalæ, Br.: Almond Oil; Oleum Amygdalæ Dulcis, *U. S.* 1860; Oil of Sweet Almond; Huile d'Amande douce, *Fr. Cod.*; Huile d'Amandes, *Fr.*; Oleum Amygdalarum, *P. G.*; Mandelöl, *G.*; Olio di mandorle dolci, *It.*; Aceite de almendras dulces, *Sp.*

This oil is obtained equally pure from sweet and from bitter almonds. In its preparation, the almonds, having been deprived of a reddish-brown powder adhering to their surface, by being rubbed together in a piece of coarse linen, are ground in a mill resembling a coffee-mill, or bruised in a stone mortar, and then pressed in canvas sacks between plates of iron slightly heated. The oil, which is at first turbid, is clarified by rest and filtration. Sometimes the almonds are steeped in very hot water, deprived of their cuticle, and dried in a stove, previous to expression. The oil is thus obtained free from color, but in no other respect better, while it is more likely to become rancid on keeping. Bitter almonds treated in this way impart an odor of hydrocyanic acid to the oil. Boullay obtained 54 per cent. of oil from sweet almonds, Vogel 28 per cent. from bitter almonds. Munch gives 55.4 per cent. as the yield of the former, and 52 per cent. as that of the latter. (*J. P. C.*, 4e sér., iii. 400.) These figures are not realized, however, in the ordinary expression methods. Schaedler (*Technologie der Fette und Öle*, 2te Auf., 532) gives 45 per cent. as the average obtained from the sweet almonds, and 38 per cent. from the bitter almonds. Though sometimes expressed in this country from imported almonds, the oil is generally brought from Europe.

Properties.—It is "a clear, pale straw-colored or colorless, oily liquid, almost inodorous, and having a mild, nut-like taste. Specific gravity: 0.910 to 0.915 at 25° C. (77° F.). Only slightly soluble in alcohol; soluble in

ether, chloroform, and benzene in all proportions. It should remain clear at -10° C. (14° F.), and it does not congeal until cooled to nearly -20° C. (-4° F.) (absence of *olive oil* or *lard oil*). If 2 Cc. of the Oil be vigorously shaken with a mixture of 1 Cc. of fuming nitric acid and 1 Cc. of water, a whitish mixture should be formed, which, after standing for some hours at about 10° C. (50° F.), should separate into a solid, white mass and a slightly colored liquid (distinction from the fixed oils of *peach* and *apricot kernels*, which give a red color, and *sesame* and *cotton seed oils*, which are colored brown). If 10 Cc. of the Oil be mixed with 15 Cc. of a solution of sodium hydroxide (1 in 6) and 10 Cc. of alcohol, and the mixture be allowed to stand at a temperature of 35° to 40° C. (95° to 104° F.), with occasional agitation, until it becomes clear, and if then diluted with 100 Cc. of water, the clear solution thus obtained upon the subsequent addition of an excess of hydrochloric acid will set free a layer of oleic acid. This, when separated from the aqueous liquid, washed with warm water, and clarified by heating on a water-bath, will remain liquid if cooled to 15° C. (59° F.).

One volume of this oleic acid, when mixed with 1 volume of alcohol, should yield a clear solution which at 15° C. (59° F.) should not deposit any fatty acids, nor become turbid upon the further addition of 1 volume of alcohol (distinction from *olive*, *arachis*, *cotton seed*, *sesame*, and other fixed oils). Expressed Oil of Almond, saponified by alcoholic potassium hydroxide T.S., should show a saponification value of 191 to 200 (see PART III, Test No. 99). If 0.3 Gm. of Expressed Oil of Almond be dissolved in 10 Cc. of chloroform in a 250 Cc. bottle or flask, and 25 Cc. of a mixture of equal volumes of alcoholic iodine T.S. and alcoholic mercuric chloride T.S. added, and if, after standing for four hours protected from the light, 20 Cc. of potassium iodide T.S. be introduced, and the mixture diluted with 50 Cc. of water, on titrating the excess of iodine with tenth-normal sodium thiosulphate V.S., an iodine value of not less than 95 nor more than 100 should be obtained (see PART III, Test No. 51). U. S. "Pale yellow, nearly inodorous, with a bland nutty taste. Soluble in *ether* and *chloroform* in all proportions. Specific gravity 0.915 to 0.920. It does not congeal until cooled to nearly -4° F. (-20° C.). If 2 cubic centimetres of the Oil be well shaken with 1 cubic centimetre of *fuming nitric acid* and 1 cubic centimetre of *water*, a whitish, not brownish-red, mixture should be formed, which after standing for 6 hours at about 50° F. (10° C.) should separate into a solid white mass and a nearly colorless liquid (absence of *peach-kernel oil* and other fixed oils)." Br. From the statement of Braconnot, it appears to contain 76 per cent. of olein and 24 per cent. of a mixture of palmitin and stearin.

According to H. Hager, the oils expressed from the large sweet and the smaller bitter almonds differ considerably, as shown by the elaidin test,—the former oil congealing rapidly, and almost completely, the latter about twelve hours later, and the smaller the bitter almond has been the more imperfectly the oil congeals. Only about one-third of the bulk congeals when the oil is from the small Oporto almonds.

Oil of almond is said to be sometimes adulterated with poppy seed oil, or other drying oils of less value. This sophistication may be detected, as suggested by Wimmec, by taking advantage of the property, belonging to the olein of the non-drying but not to that of the drying oils, of being converted into solid elaidic acid by the action of nitrous acid. By treating iron filings with nitric acid in a flask, nitrous acid is produced, which is to be conducted into water upon which the suspected oil is placed. If the almond oil contains even a small quantity of poppy seed oil, or other drying oil, this will remain in the form of drops on the surface, while the genuine oil will be converted entirely into crystallized elaidin. (*J. P. C.*, Dec. 1862, p. 500.) Colza oil, another not uncommon adulteration, may be detected, according to Schneider, by the action of silver nitrate. Dissolve the oil in twice its volume of ether, add about 30 drops of concentrated alcoholic solution of the nitrate, shake the mixture, and allow it to stand in the dark. If there be much colza oil, the lower part of the liquid will become first brown and then black; if but little, the brown color will not appear for twelve hours, but the discoloration will always be obvious on the evaporation of the ether. (*P. J.*, March, 1862.)

Peach and apricot kernel oils are very extensively used in the adulteration of almond oils and sometimes entirely replace the true almond oil in commercial samples. The close relationship of these oils makes it impossible to detect them by the quantitative reactions. (For qualitative tests see the official tests, page 832.)

According to Hager, if equal volumes of the oil and of 25 per cent. nitric acid are shaken together in a test tube, an emulsion-like mixture is produced, which separates on standing. All true almond oils yield a white mixture, and the oils remain white for many hours after separation, but the oils of *peach* and *apricot seeds* turn yellowish at once on being shaken with the acid, and the color afterwards deepens, and in half an hour is of a rather deep red-yellow. (*A. J. P.*, 1870, p. 408.) J. D. Bieber communicates the following test. Equal weights of pure concentrated sulphuric acid, red fuming nitric acid, and water are mixed, and the mixture allowed to cool. On mixing five parts of the oil with one part of this acid liquid, *pure almond oil* gives a yellowish-white liquid; *oil of peach kernels* assumes the red color of peach blossoms, turning to dark orange; *benne oil* turns pale yellowish

red, then dirty orange-red; *poppy* and *walnut* oils yield a somewhat whiter liquid than almond oil. This test permits the detection of 5 per cent. of peach kernel and benne oil. Mixed with pure nitric acid, sp. gr. 1.40, *almond* oil yields a pale-yellowish liquid, *peach kernel* oil a red, *benne* oil a yellowish green, afterwards reddish, and *poppy* and *walnut* oils a white mixture. It was found that the oil expressed, cold or warm, from either fresh almonds or from such as had been kept up to ten years, gave the same reaction. Most of the commercial oil was found to be adulterated with the oil of either peach kernels or benne seed. (*A. J. P.*, Dec. 1877.)

Oil of almond may be used for the same purposes as is olive oil, and, when suspended in water by means of mucilage or the yolk of egg and loaf sugar, forms a pleasant emulsion, useful in pulmonary affections attended with cough.

Dose, one fluidrachm to one fluidounce (3.75 to 30 Cc.).

OLEUM ANETHI. Br.

OIL OF DILL

(ô'le-üm æ-ně'thî)

"The oil distilled from Dill Fruit." *Br.*

Huile volatile d'Aneth, Essence d'Aneth, *Fr.*; Dill, Dillöl, *G.*

Oil of dill is of a pale yellow color, with the odor of the fruit, and a hot, sweetish, acrid taste. Its sp. gr. varies between 0.895 and 0.915. The fruit yields about 3.5 per cent. of it. The oil is a mixture of phellandrene, a paraffin hydrocarbon, and 40 to 60 per cent. of *d*-carvone, $C_{10}H_{14}O$, with *d*-limonene, $C_{10}H_{16}$. (See *Oleum Cari*.) "Color pale yellow, odor that of the fruit, taste sweet and aromatic. Specific gravity 0.905 to 0.920. It rotates the plane of a ray of polarized light not less than 70° to the right, at $60^\circ F.$ ($15.5^\circ C.$), in a tube 100 millimetres long." *Br.* R. Nietski obtained from dill, the fruit of *Anethum graveolens* a volatile oil, which commenced to boil at $155^\circ C.$ ($311^\circ F.$), the boiling point rising gradually to $260^\circ C.$ ($500^\circ F.$). About 10 per cent. of the oil consists of a hydrocarbon, $C_{10}O_{18}$, having the boiling point from 155° to $160^\circ C.$, 60 per cent. boiling at from 170° to $175^\circ C.$ (338° to $347^\circ F.$), of the same composition, and 30 per cent. with the boiling point from 225° to $230^\circ C.$ (437° to $446^\circ F.$), composition $C_{10}H_{14}O$, and identical with carvol. The odor of the first portion of hydrocarbon is similar to that of turpentine; that of the second portion resembles oil of mace, but when mixed

with a little carvol the characteristic dill odor is at once produced. (*A. J. P.*, 1874.) The oil is sometimes used for the preparation of dill water.

Dose, from three to ten minims (0.2 to 0.6 Cc.).

OLEUM ANISI. U. S., Br.

OIL OF ANISE

(ô'le-üm æ-nî'sî)

"A volatile oil distilled from Anise or from the fruit of Star Anise, *Illicium verum* Hooker filius (Fam. *Magnoliaceæ*). It should be kept in well-stoppered, amber-colored bottles, protected from light, and, if it has separated into a liquid and a solid portion, it should be completely liquefied by warming, and then well shaken, before being dispensed." *U. S.* "The oil distilled from the Anise Fruit; or from the fruit of the star-anise, *Illicium verum*, *Hook. fil.*" *Br.*

Huile volatile d'Anis vert (Badaine), *Fr.* *Od.*; Essence d'Anis, *Fr.*; Oleum Anisi, *P. G.*; Anethol, Anisöl, *G.*; Essenza di anice, *It.*; Esencia de anis, *Sp.*

The product of oil from anise is variously stated at from 1.56 to 3.12 per cent. The oil employed in this country is imported. It is colorless or yellowish, with the peculiar odor and taste of the seed. At $50^\circ F.$ it crystallizes in flat tables, and it does not melt under $62^\circ F.$ Its sp. gr. increases with age, and is variously given at from 0.9768 to 0.9903. It is soluble in all proportions in alcohol of 0.806; but alcohol of 0.840 dissolves at $25^\circ C.$ ($77^\circ F.$) only 42 per cent. Ether dissolves oil of anise in all proportions.

Properties.—"A colorless or pale yellow, thin, and strongly refractive liquid, having the characteristic odor of anise, and a sweetish, mildly aromatic taste. Specific gravity: 0.975 to 0.985 at $25^\circ C.$ ($77^\circ F.$). The Oil should be laevogyrate, the angle of rotation being -2° in a 100 Mm. tube, at a temperature of $25^\circ C.$ ($77^\circ F.$) (absence of oil of fennel, etc.). Soluble in an equal volume of alcohol, forming a clear solution, also in 5 volumes of 90 per cent. alcohol (absence of petroleum, of most fixed oils, and of oil of turpentine). An alcoholic solution of Oil of Anise is neutral to litmus paper, and should not assume a blue or brownish color on the addition of a drop of ferric chloride T.S. (absence of some volatile oils containing phenols). When the Oil is shaken with water in a narrow graduated cylinder, its volume should not be diminished (absence of alcohol). When tested according to the following method, the congealing point of Oil of Anise should not be below $15^\circ C.$ ($59^\circ F.$): Transfer about 10 Cc. of the Oil to a test-tube, placed in water cooled with ice; insert a thermometer at once into the Oil, and allow it to remain undisturbed until its temperature has fallen to

about 6° C. (42.8° F.). Induce crystallization either by rubbing the inner wall of the test-tube with the thermometer, or by the addition of a particle of solid anethol, remove the test-tube from the bath, and stir continuously during the solidification of the Oil. The highest temperature reached during the crystallization is regarded as the congealing point." *U. S.* "Colorless or pale yellow; with the odor of the fruit, and a mildly aromatic taste. It congeals, when stirred, at temperatures between 50° and 59° F. (10° to 15° C.) and should not again become liquid below 59° F. (15° C.). Specific gravity at 68° F. (20° C.) 0.975 to 0.990. It rotates the plane of a ray of polarized light slightly to the left." *Br.* It consists of a small quantity of terpene, $C_{10}H_{16}$, but mainly of *anethol*, $C_{10}H_{12}O$ (about 85 per cent.), which is present, however, in two isomeric modifications, one solid at ordinary temperatures and heavier than water (*solid anethol*), the other liquid and more volatile (*estragol* or *methyl chavicol*). *Anethol*, both in the liquid and in the solid form, is present, and is the chief constituent of the oils of *anise*, *star anise*, and *fennel*. The solidification test of the *U. S. P.* (8th Rev.) is based upon the anethol content. By oxidation, by means of nitric acid, or chromic anhydride, the different forms of anethol¹ yield *anisic acid*, $C_8H_8O_4$. Oil of anise, by exposure to air, is oxidized with the formation of *anisic aldehyde*, *acetic aldehyde* and *anisic acid*, and becomes less disposed to concrete.

In consequence of its high price, it is frequently adulterated with spermaceti, wax, or camphor. The first two may be detected by their insolubility in cold alcohol, the last by its odor. In one instance as much as 35 per cent. of spermaceti was found. Schimmel & Co. have found fennel stearoptene in commercial oil of anise. (*Ph. Rev.*, 1897, 94.) Procter met with a parcel, of which not less than five-sixths was alcohol. (*A. J. P.*, xxvii. 513.) Its comparative mildness adapts it to infantile cases. Most of the oil of anise of commerce is the oil of *star aniseed* (*Oleum Badiani*, or *Oleum Illici*). Oil of anise has also been distilled from the sweet cicely, *Osmorrhiza longistylis*, of the United States and Canada. (*Ph. Rund.*, July, 1887.) For description and analysis of Russian oil of anise, see *P. J.*, 1896, 164, also 243. Anisic acid is said to be antiseptic, resembling salicylic acid in its action.

Dose, from three to five minims (0.2 to 0.3 Cc.).

OLEUM ANTHEMIDIS. Br.

OIL OF CHAMOMILE

(ô'le-üm an-thēm'î-dīs)

"The oil distilled from Chamomile Flowers." *Br.*

Oleum Chamomillæ Romanæ; Essence de Camomille romaine, *Fr.*; Römisch-Kamillenöl, *G.*

This oil was introduced into the British Pharmacopœia 1885 with the direction that it should be distilled in Britain. No such restriction is found in the Pharmacopœia of 1898. It is seldom prepared in this country. Baumé obtained thirteen drachms of the oil from eighty-two pounds of the flowers; according to Brande, the average product of 100 pounds is two pounds twelve ounces. It has the peculiar odor of chamomile, with a pungent somewhat aromatic taste. When recently distilled it is of a pale sky-blue or greenish-blue color, which changes to yellow or brownish on exposure. "Specific gravity 0.905 to 0.915." *Br.* The oil was thoroughly investigated in Fittig's laboratory during the years 1878-79. It was found to consist of a mixture of *angelic* and *tiglinic esters of isobutyl, isamyl, hexyl*, and probably a higher alcohol. Angelic acid and tiglinic acid are isomeric, and have the formula $C_8H_8O_4$. The relative proportions of these two acids varied in different oils. An ester of a lower homologue of angelic acid having the formula $C_6H_8O_4$ was also obtained. Naudin obtained a small amount of a solid paraffin $C_{18}H_{36}$, melting at 63° C. to 64° C., to which the name of "*anthemen*" was given. (Gildemeister and Hoffmann, *Aetherische Oele*, p. 881.) It has sometimes been employed in spasm of the stomach, and as an adjunct to purgative medicines. Its chief use, however, appears to be as an ingredient of the extract of chamomile of the British Pharmacopœia, to which it is added in order to supply the place of the oil driven off by the heat used in its preparation. This oil must not be confounded with that of *Matricaria Chamomilla*, employed on the continent of Europe under the name of oil of chamomile. (See *Matricaria*.)

Dose, three to five minims (0.2 to 0.3 Cc.).

Off. Prep.—Extractum Anthemidis, *Br.*

OLEUM AURANTII CORTICIS. U. S.

OIL OF ORANGE PEEL

(ô'le-üm au-rân'ti-i cōr'ti-cīs)

"A volatile oil obtained by expression from the fresh peel of the Sweet Orange. It should be kept in small, well-stoppered, amber-colored bottles, in a cool place, so as to avoid, as far as possible, the development of a terebinthinate odor. Oils that have developed such an odor should not be dispensed." *U. S.*

Oleum Aurantium; Essential Oil of Orange Peel, Essence of Orange; Huile volatile d'Orange, *Fr.* Cod.; Apfelsinenchalenöl, Pomeranzenschalenöl, *G.*; Essenza di arancio amara (Essenza della corteccia), *It.*

This oil is used only for flavoring purposes, and has been introduced principally because of its employment in elixirs and in *Spiritus Aurantii Compositus*.¹

Oil of orange is prepared in Calabria and Sicily in three ways: 1, by scraping off the exterior part of the rind and submitting it to expression; 2, by putting the scrapings into hot water, depressing the pulp beneath, and skimming off the oil as it rises; 3, by distillation. The best Sicily orange oil is procured by dexterous compression, within a cask, of the fresh rind by the hand, the oil being driven out in jets. It is sometimes absorbed by a sponge. (*A. J. P.*, 1868.) It is largely made at Messina, and in the south of France. It is also extracted by the *écuelle* process,² and partly from the Bigarade and partly from the sweet or Portugal orange, the scarcely ripe fruit being in either case employed. The oil made from the former is much more valuable than that obtained from the latter, and the two are distinguished in price-currents as *Essence de Bigarade* and *Essence de Portugal*.

Properties.—Oil of orange peel consists, as has been shown by Wallach, of *d-limonene* to the extent of at least 90 per cent.; of the remainder, about 5 per cent. are the odorous constituents, among which are *citral*, traces of *citronellal*, and the methyl ester of *anthranilic acid*. The inner thick part of the rind contains also a bitter principle, called *hesperidin*, discovered by Lebreton in 1828, but more fully studied by Hoffmann (*Ber. d. Chem. Ges.*, 1876, pp. 26, 685). It is best prepared from the unripe bitter orange. Its formula is $C_{22}H_{32}O_{12}$, and it is a glucoside, as is shown by the reaction with diluted sulphuric acid, whereby it is decomposed into *hesperetin*, $C_{16}H_{14}O_6$, and glucose, $C_6H_{12}O_6$.

The U. S. Pharmacopœia describes the oil as "a pale yellow liquid, having the characteristic, aromatic odor of orange, and an aromatic taste. Specific gravity: 0.842 to 0.846 at 25° C. (77° F.). Its optical rotation should be dextrogyrate, not less than 95° in a 100 Mm. tube, at a temperature of about 25° C. (77° F.) (absence of oil of turpentine, etc.). When subjected to careful fractional distillation, any Oil coming over below 170° C. (338° F.) should not yield pinene nitrosochloride and nitrosopinene (derived from added oil of turpentine) when tested in the following manner: Dissolve 5 Cc. of the fraction to be tested

in one-half its volume of glacial acetic acid, add 5 Cc. of amyl nitrite, cool thoroughly in a freezing mixture, and add, very gradually, 5 Cc. of a mixture of equal volumes of hydrochloric acid and glacial acetic acid. Collect any crystals which separate from the blue or greenish liquid upon standing, on a force filter, and wash them with a little alcohol. Transfer the crystals to a flask, add 5 Cc. of alcoholic potassium hydroxide T.S., and heat on a water-bath fifteen minutes. Pour the solution into cold water, collect the precipitate, and wash it with cold water. Recrystallize the dried precipitate from alcohol, and determine the melting point of the crystals. Nitrosopinene melts at 132° C. (269.6° F.), whereas nitro-solimonene or carboxime (from limonene, one of the normal constituents of Oil of Orange Peel) melts at 72° C. (161.6° F.)." *U. S.* A waxy non-volatile substance is present in oil of orange, which interferes with the transparency of solution made with 90 per cent. alcohol. This oil is one of the most difficult to preserve. A method for its preservation, which we have used for years, is to shake the oil briskly with one-eighth of its volume of distilled water, and allow it to separate, then remove the essential oil, filter rapidly if necessary, and mix the filtered oil with 95 per cent. alcohol in the proportion of one volume of the oil to seven volumes of alcohol.

Dose, three to five minims (0.2 to 0.3 Cc.).

Off. Prep.—*Spiritus Aurantii Compositus*, *U. S.*

OLEUM BETULÆ. U. S.

Oil of BETULA [Oleum Betulæ Volatile, Pharm.
1890, Oil of Sweet Birch]

(ô'le-üm bêt'û-læ)

"A volatile oil obtained by maceration and distillation from the bark of the Sweet Birch, *Betula lenta* Linné (Fam. *Betulaceæ*). It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

Oleum Betulæ Lentæ; Oil of Sweet Birch; Essence de Bouleau ou Bétula, *Fr.*; Birkenrindenöl, *G.*

The *Betula lenta*, cherry birch, sweet birch, black birch, mountain mahogany, is a large American tree resembling in its dark, chestnut-brown bark, the general shape of its leaves, and its whole appearance, the garden cherry. It grows northward from New England to Ohio and southward in the Blue Ridge as far as South Carolina and Georgia. It is especially characterized by its heart-ovate, pointed, sharply and finely doubly serrate leaves, and short petioles. The underneath veins of the leaves are hairy, as are also the elliptical, thick, fruiting catkins, the lobes of whose venous scales are nearly equal, obtuse, and diverging.

¹ *Spiritus Aurantii*, U. S. 1890. *Spirit of Orange*. "Oil of Orange Peel, fifty cubic centimeters [or 1 fluidounce, 331 minims]; Deodorized Alcohol, nine hundred and fifty cubic centimeters [or 32 fluidounces, 59 minims], to make one thousand cubic centimeters [or 33 fluidounces, 390 minims]. Mix them." *U. S.* 1890.

This was introduced at the U. S. 1880 revision. There was very little necessity for its introduction, because of the adoption of the tincture of sweet orange peel, which is identical in properties with the spirit, although not so strong. It serves a useful purpose, however, as a means of preserving the oil. It is an excellent solution for flavoring purposes.

² For an illustration of the *écuelle*, see Remington's *Practice of Pharmacy*, Fourth Edition, p. 806.

In commerce the oil of sweet birch is chiefly sold as the oil of wintergreen. It is very largely distilled by the mountaineers or small farmers, many of whom put indiscriminately into their stills the wintergreen and the bark of the birch, or at least mix the products before selling. It is in general use, under the name of oil of gaultheria; it differs from the latter so slightly, in chemical constituents, that for practical purposes the differences may be disregarded; oil of sweet birch contains a fraction of 1 per cent. of a paraffin and an ester, $C_{14}H_{24}O_2$, not present in oil of gaultheria. For a description of the apparatus used to distil oil of sweet birch, see *A. J. P.*, 1882, 49. The so-called "light oil" of distillers, according to Kennedy, is simply the oil with water and dirt. Oil of sweet birch "is optically inactive, but otherwise has essentially the same properties as, and conforms to the reactions and tests given under, *Oleum Gaultheriæ*." *U. S.* Oil of birch does not differ in its physiological and remedial properties from oil of gaultheria.

Dose, five to thirty minims (0.3 to 1.8 Cc.).

OLEUM CADINUM. U. S., Br.

Oil of CADE [Oil of Juniper Tar, Oleum Juniperi Empyreumaticum]

(ō'le-ŭm cā-dī'nŭm)

"A product of the dry distillation of the wood of *Juniperus Oxycedrus* Linné (Fam. *Coniferae*)." *U. S.* "An empyreumatic oily liquid obtained by the destructive distillation of the woody portions of *Juniperus Oxycedrus*, Linn., and some other species." *Br.*

Juniper Tar Oil; Hulle de Cade, *Fr.*; Kadeöl, *Kadöl*, *G.*

The *Juniperus Oxycedrus*, Linné, prickly cedar, or large brown-fruited juniper, is a common tree in the waste places and stony hill-sides of the Mediterranean districts of Northern Africa, Spain, Portugal, and France, reaching up in its distribution as high as 3000 feet in the Apennines. It commonly attains a height of from ten to twelve feet, sometimes much more, with long spreading branches and slender drooping branchlets, covered with light-green scattered and spreading leaves of medium size, lanceolate or awl-shaped, sharply pointed, having two furrows on their upper edge. The fruits are numerous, large (half an inch in diameter), globular, shining, reddish or chestnut-brown, and marked on the apex with two white lines.

From the heart-wood of this tree the oil of cade is prepared by a process of distillation in ovens *per descensum*, similar to that practised in the making of ordinary tar. It is a brownish or dark brown liquid, much more mobile and less thick than tar, having a tar-like but distinct odor, and a smoky, acrid, bitterish, disagreeable taste. In mass it is

dark and opaque, but in very thin layers clear; the oil contains phenols and a sesquiterpene termed *cadinene*, $C_{15}H_{24}$, the latter boiling at from 274° to 275° C. "A brownish or dark brown, clear, thick liquid, having a tarry odor, and an empyreumatic, burning, somewhat bitter taste. It is almost insoluble in water, but imparts to it an acid reaction; it is only partially soluble in alcohol, but it is completely soluble in ether." *U. S.* The British Pharmacopœia describes it as "A dark reddish-brown or nearly black, more or less viscid, oily liquid, with a not unpleasant empyreumatic odor and an aromatic bitter and acrid taste. Specific gravity about 0.990. It is soluble in ether and chloroform; partially soluble in cold, almost wholly in hot alcohol (90 per cent.). It is very slightly soluble in water. The filtered aqueous solution is almost colorless and possesses an acid reaction." *Br.* Yaucher recommends acetone for disguising the odor of oil of cade, and proposes an oil of cade collodion in which acetone is used to dissolve the pyroxylin instead of the usual solvents. (*C. D.*, 1897, 16.)

Uses.—Oil of cade has been used locally, by the peasantry, in the treatment of the cutaneous diseases of domestic animals almost from time immemorial. More recently it has been largely employed in the treatment of chronic eczema, psoriasis, and other skin diseases of man, and has also been found to be an efficient parasiticide in psora and favus. It is applied, sometimes of full strength, sometimes diluted with a bland oil, well rubbed into the affected parts with the fingers, or with a cloth, and is also made into ointments, and especially into soaps.¹ A glycerite is also prepared. It is very rarely, if ever, used internally, but probably resembles oil of tar in its physiological action.

Dose, one to three minims (0.06 to 0.2 Cc.).

OLEUM CAJUPUTI. U. S., Br.

Oil of CAJUPUT

(ō'le-ŭm cāj-ŭ-pŭ'tī)

"A volatile oil distilled from the fresh leaves and twigs of *Melaleuca Leucadendron* Linné (Fam. *Myrtaceæ*), yielding, when assayed by the process given below, not less than 55 percent., by volume, of cineol. It should be kept in well-stoppered, amber-colored bottles, in a cool place." *U. S.* "The oil distilled from the leaves of *Melaleuca Leucadendron*, Linn. (*Melaleuca Cajuputi*, *Roxb.*)." *Br.*

Oleum Cajuputi; Essence de Cajuput, Hulle volatile de Cajuput, *Fr.*; Cajuputöl, *G.*; Essenza di Cajuput, *It.*; Esencia de Cajuput, *Sp.*; Kayuputieh, *Mal.*

¹ In the *Edinb. Monthly Journ.* for July, 1852 (page 66), it is stated that the soap is made by distilling the tar, incorporating the volatile oil obtained with a fixed oil, and then saponifying this with soda. It is in the form of black balls, readily unites with water, and may be applied to the surface like any other soap. The best plan is probably to apply it at bedtime and wash it off next morning.

It was long supposed that the oil of cajuput was derived from *Melaleuca Leucadendron*, but from specimens of the plant affording it, sent from the Moluccas and cultivated in the botanical garden of Calcutta, Roxburgh concluded it to be a distinct species, and gave it the name of *M. Cajuputi*. It corresponds with the *arbor alba minor* of Rumphius, and is a smaller plant than the *M. Leucadendron*. Benthams, however, probably with correctness, considers it simply a smaller variety of *M. Leucadendron*, a tree of wide spread habitat, reaching into India, the Philippines, and even Australia. It is possible, however, that the oil may be obtained from different species of *Melaleuca*, as Stickel of Jena, succeeded in procuring from the leaves of *M. hypericifolia*, cultivated in the botanical garden of that place, a specimen of oil not distinguishable from the cajuput oil of commerce, except by a pale-green color. (*Ann. Pharm.*, xix. 224.) *M. viridifolia* and *M. latifolia*, large trees growing abundantly in the island of New Caledonia, yield a volatile oil very analogous to the oil of cajuput.¹ The leaves of different species of *Melaleuca* have been used advantageously, in the form of bath, in *chronic rheumatism*. (*Ann. Thér.*, 1861, p. 67.) An extract of *M. paraguayensis* has been used with alleged advantage in rheumatism and other diseases. (*Med. Rec.*, xvi.)

Melaleuca Leucadendron, Linné. *M. Cajuputi*, Rumphius, *Herbar. Amboinense*, tom. ii. tab. 17; Roxburgh, *Trans. Lond. Med. Bot. Soc.*, 1829; *A. J. P.*, vol. i. p. 193.—*M. minor*, De Candolle; *B. & T.* 108.—This tree grows with an erect but crooked stem, and scattered branches, the slender twigs of which droop like those of the weeping willow. The bark is of a whitish ash color, very thick, soft, spongy, and lamellated, throwing off its exterior layer from time to time in flakes. The leaves have short footstalks, are alternate, lanceolate, when young sericeous, when full-grown smooth, deep green, three- and five-nerved, slightly falcate, entire, from three to five inches long, from one-half to three-quarters of an inch

broad, and when bruised exhale a strong aromatic odor. The flowers are small, white, inodorous, sessile, and disposed in terminal and axillary downy spikes, with solitary, lanceolate, three-flowered bracts. The filaments are three or four times longer than the petals, and both are inserted in the rim of the calyx. The oil is obtained from the leaves by distillation. It is prepared chiefly in Amboyna and Bourbo, and is exported from the East Indies in glass bottles. The small proportion yielded by the leaves, and the extensive use made of it in India, render it somewhat costly.

Properties.—Cajuput oil is very fluid, transparent, of a fine green color, a lively and penetrating odor analogous to that of camphor and cardamom, and a warm, pungent taste. Upon rectification the green color disappears. It is very volatile and inflammable, burning without any residue. The sp. gr. varies from 0.914 to 0.9274. Its chief constituent has the formula $C_{10}H_{16}O$, and by repeated distillation over phosphoric oxide the hydrocarbon, $C_{10}H_{16}$, called *cajuputene*, can be obtained. The oil is, therefore, said to contain *cajuputene hydrate*, or *cajuputol*. The identity of cajuputol with *cineol* and *eucalyptol* from *Eucalyptus Globulus* in both chemical and physical properties was established by Wallach in 1884 and by C. Jahns. (*A. J. P.*, 1885, 237.) It boils at $175^{\circ} C.$ ($347^{\circ} F.$). A second constituent of the formula $C_{10}H_{16}O$ is the solid *terpineol*, which is present both in the free state and as acetic ester. A small amount of *l-pinene* and traces of aldehydes have been found, including *valeraldehyde* and *benzaldehyde*. (*Schimmel & Co.'s Report*, April, 1897.) Oil of cajuput is "a thin, colorless or greenish liquid, having a peculiar, agreeable, distinctly camphoraceous odor, and an aromatic, slightly bitter taste. Specific gravity: 0.915 to 0.925 at $25^{\circ} C.$ ($77^{\circ} F.$). It is miscible with alcohol in all proportions, also soluble in 1 part of 80 percent. alcohol. The alcoholic solution should be neutral. Oil of Cajuput is *lævogyrate*; the angle of rotation should not exceed -2° in a 100 Mm. tube, at a temperature of $25^{\circ} C.$ ($77^{\circ} F.$). On shaking 5 Cc. of the Oil with 5 Cc. of water containing 1 drop of diluted hydrochloric acid, a reddish-brown color should not be produced in the acid liquid when separated from the Oil, if a drop of potassium ferrocyanide T.S. be added (absence of *copper*)." *U. S.* "Bluish-green, with an agreeable penetrating camphoraceous odor, and an aromatic bitterish camphoraceous taste. Specific gravity from 0.922 to 0.930. It should become semi-solid on being stirred, when cold, with a third or half its volume of phosphoric acid of commerce of specific gravity 1.750 (presence of a due proportion of *cineol*)." *Br.* The value of oil of cajuput is determined by its *cineol* content and the official assay is as follows:

Assay for Cineol.—"Introduce into a beaker a solution prepared by dissolving 10 Cc. of

¹ It seems to be uncertain how much of the oil of cajuput of commerce is produced by the New Caledonia trees. In the *B. G. T.*, xcvii., the volatile oil of *Melaleuca flaviflora* is said to be sent in large quantities, under the name of *miaooul*, from New Caledonia to the East. A pale-yellow oil occurring in French commerce as "*gomenol*," or oil of *miaooul* or *essence de miaooul* is obtained from the *Melaleuca viridiflora*, which yields it about 2.5 per cent. According to G. Bertrand, it has a density of 0.922 and deviates polarized light $6^{\circ} 42'$ to the right. He finds that it contains minute quantities of amylic alcohol, but is chiefly composed of a dextrogyrate terebinthene, $C_{10}H_{16}$, *cineol*, a hydrocarbon (probably *citrene*) boiling at $175^{\circ} F.$, and a *terpinol*. This composition is identical with that of the *terpinol* of List (*C. R. A. S.*, cliv. 996, cvl. 663), obtained by heating with acidulated water the terpene, $C_{10}H_{16} \cdot 2H_2O$, resulting from the spontaneous hydration of terpene, $C_{10}H_{16}$, the natural product being thus readily imitated artificially in the laboratory by extremely simple reactions. (*C. R. A. S.*, cxvi. 1070.) According to Dobousquet de Laborières (*B. G. T.*, cxxxvi.) oil of *miaooul* contains sixty-six per cent. of *cineol* and is especially useful in *cystitis* and *chronic bronchitis*. Blanc commends it as a general therapeutic substitute for oil of cajuput. (*R. T.*, lix.)

oil of Cajuput in 50 Cc. of purified petroleum benzin; immerse the beaker in a freezing mixture and add phosphoric acid, drop by drop, with constant stirring, until the white magma of cineol phosphate formed, begins to assume a yellowish or pinkish tint; then transfer the magma to a force filter, wash it with cold purified petroleum benzin, and then dry it by pressure between two porous plates. Transfer the precipitate (cineol phosphate) to a narrow graduated cylinder, and add warm water, which will cause separation of the cineol. The volume, in cubic centimeters, of the separated oily liquid, multiplied by 10, represents the volume percent. of cineol." *U. S.* The oil is wholly soluble in alcohol. When it is distilled, a light, colorless liquid first comes over, and afterwards a green and denser one. The green color has been ascribed to a salt of copper derived from the vessels in which the distillation is performed, and Guibourt obtained two grains and a half of copper oxide from a pound of the commercial oil. But neither Brande nor Goertner could detect copper in specimens examined by them, and Lesson, who witnessed the process for preparing the oil at Bouro, attributes its color to chlorophyll or some analogous principle, and states that it is rendered colorless by rectification. Guibourt, moreover, obtained a green oil by distilling the leaves of a *Melaleuca* cultivated at Paris. A fair inference is that the oil of cajuput is naturally green, but that as found in commerce it sometimes contains copper, either accidentally present or added with a view of imitating or maintaining the fine color of the oil. The proportion of copper, however, is not so great as to forbid the internal use of the oil, and the metal may be separated by distillation with water, or by agitation with a solution of potassium ferrocyanide. This statement as to the frequent occurrence of copper in the cajuput oil of commerce, though at the same time its presence is not desirable, has been confirmed by experiments by Edward Histed, who found copper in all of six specimens of the commercial oil, obtained from different sources. When redistilled, the oil became perfectly colorless, but after a few days' exposure to copper filings reassumed its green color. (*P. J.*, 1872, p. 804.)

Oil of cajuput is said to be often adulterated with oils derived from other than the official species of *Melaleuca*. Oil of rosemary, and oil of turpentine, impregnated with camphor and colored with the resin of milfoil, are also said to be employed as adulterants. The best test, according to Zeller, is iodine, which, after a moderately energetic reaction, with little increase of temperature and but a slight development of orange vapors, occasions immediate inspissation into a loose coagulum, which soon becomes a dry, greenish-brown, brittle mass.

Uses.—This oil is highly stimulant, producing when swallowed, a sense of heat, with an

increased fulness and frequency of pulse, and exciting in some instances profuse perspiration. It is much esteemed by the Malays and other people of the East, who consider it a panacea. The complaints to which it is best adapted are probably *chronic rheumatism*, and *spasmodic affections of the stomach and bowels*, unconnected with inflammation. It has been extolled as a remedy in *spasmodic cholera*, and has been used also as a diffusible stimulant in *low fevers*. It is said to have been used in the collapsed state of cholera, with unexpected success, in the dose of from fifteen grains to a drachm (1.0 to 3.9 Gm.) in a single potion. (*Ann. Thér.*, 1867, p. 71.) Diluted with an equal proportion of olive oil, it is applied externally to relieve *gouty* and *rheumatic pains*. Like most other highly stimulating essential oils, it relieves *toothache* if introduced into the hollow of the carious tooth. Delvaux, who has made extensive use of this oil, has found it beneficial, given internally, in *dyspepsia* with flatulence, in the early stages and milder forms of *cholera*, in *verminose affections* in children, in *chronic laryngitis* and *bronchitis*, in *chronic catarrh of the bladder*, in *chronic rheumatism of the joints* with little or no swelling, and in painful *chronic rheumatism of the muscles and fibro-muscular tissues*, whether external or internal. Externally applied, Delvaux has derived great benefit from it in various cutaneous diseases, as *pityriasis*, *psoriasis*, and especially in that extremely obstinate affection of the face, *acne rosacea*, which he has often succeeded in curing by the simple application of this oil three times a day. (*Ann. Thér.*, 1862, p. 38.)

Dose, from three to ten minims (0.2 to 0.6 Cc.).

OLEUM CARI. U. S. (Br.)

OIL OF CARAWAY

(ō'le-ŭm cā'ri)

"A volatile oil distilled from Caraway and rectified by steam distillation. It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "The oil distilled from Caraway Fruit." *Br.*

Oleum Carvi, Br.; Huile volatile de Carvi, Fr. *Cod.*; Essence de Carvi, Fr.; Oleum Carvi, P. G.; Kümmelöl, Carvon, G.

This oil is prepared to a considerable extent by our distillers. The fresh fruit as cultivated in Holland yields nearly 6 per cent. of oil, while the German fruit yields about 4 per cent. The oil of caraway is somewhat viscid, of a pale yellow color, becoming brownish by age, with the odor of the fruit, and an aromatic acrid taste. Its sp. gr. is differently given at 0.946 (Baumé), 0.931 (Brande), 0.916 (Buignet), and 0.905 to 0.915 at 25° C. (*U.*

S. P.). It is dextrogyrate in its relation to polarized light. (Buignet, *J. P. C.*, Oct. 1861, p. 261.) It consists of two liquid oils, of different boiling points, and separable by distillation:—one a hydrocarbon called *carvene*, $C_{10}H_{16}$, of the sp. gr. 0.849 and boiling point 176° C. (349° F.), now recognized as identical with *d-limonene*, the other, the valuable constituent, *d-carvone*, $C_{10}H_{14}O$, of the sp. gr. 0.9638 and boiling point 224° C. (435° F.). This latter constituent is often extracted from the oil and prepared in a pure state by taking advantage of the formation of a crystalline compound of carvone and hydrogen sulphide, which can then be decomposed by treatment with alcoholic potassium hydroxide.

Properties.—It is officially described as “a colorless or pale yellow, thin liquid, having the characteristic, aromatic odor of caraway, and a spicy taste. Specific gravity: 0.905 to 0.915 at 25° C. (77° F.). Soluble in an equal volume of alcohol; also in from 3 to 10 volumes of 80 percent. alcohol. Oil of Caraway is dextrogyrate, the angle of rotation varying from $+70^{\circ}$ to $+80^{\circ}$ in a 100 Mm. tube, at a temperature of 25° C. (77° F.).” *U. S.* “Colorless or pale yellow, with the characteristic odor of the fruit, and a spicy taste. Specific gravity 0.910 to 0.920.” *Br.* For additional tests, see *Schim. Rep.*, 1893, 10; also *Bull. Pharm.*, 1894, 257. Kremers and Schreiner (*Ph. Rev.*, 14, 76) recommend a method of determining the value of oil of caraway based on the conversion of carvone into its oxime, and the separation of the carvoxime from the terpenes by steam distillation; it is as follows: “To a solution of 10 Gm. of oil, dissolved in 25 Cc. of alcohol, 5 Gm. of hydroxylamine hydrochloride and 6.5 Gm. of sodium bicarbonate are added. This mixture is boiled on a water bath for half an hour in a flask connected with a reflux condenser, 25 Cc. of water are then added, and the alcohol is distilled off on the water bath. Steam is then passed through the liquid until traces of carvoxime come over. The last portions of the distillate are collected separately in test tubes, and when traces of crystals of carvoxime appear on the surface, the operation is interrupted. The tube of the condenser is washed with a little hot water, and this, as well as the last collected distillate, containing some carvoxime, is returned to the flask. The contents of the flask are allowed to cool, and after the carvoxime has completely solidified, it is removed from the sides of the flask by means of a loop of stiff wire, thrown upon a force filter, washed, and dried by suction. The air-dried carvoxime is transferred to a tared glass dish and heated for 1 hour on a water bath, and when cool, weighed. To the weight thus obtained 0.100 Gm. is added, as this is about the quantity lost during heating. From the weight of the carvoxime that of the carvone may be readily calculated, 164.67 parts of the former corresponding to 149.66 parts of the latter, or the weight of carvoxime

obtained, expressed in Gm., when multiplied by 0.9088, gives the weight of the equivalent amount of carvone.”

When oil of caraway is distilled over glacial phosphoric acid or powdered sodium hydroxide, the distilled liquor being poured back into the retort until it ceases to have the odor of caraway, an oily liquid is obtained, having a very disagreeable odor, and a strong taste. This product, to which the name of *carvacrol* has been applied, has been found to give immediate relief to *toothache*, when inserted on cotton into the cavity of a carious tooth. (See *Am. J. M. S.*, N. S., xv. 532.) Carvacrol (isopropyl-o-cresol) is found to be of the same chemical composition as carvone and is formed from it by molecular rearrangement. Oil of caraway is much used to impart flavor to medicines, and to correct their nauseating and gripping effects.

Dose, from one to ten minims (0.06 to 0.6 Cc.).

OLEUM CARYOPHYLLI. U. S., Br.

OIL OF CLOVES

(*ôlê-ûm câr-ÿ-ô-phÿl'li*)

“A volatile oil distilled from Cloves, yielding, when assayed by the process given below, not less than 80 percent., by volume, of eugenol. It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light.” *U. S.* “The oil distilled from Cloves.” *Br.*

Hulle volatile de Girofle, Fr. Cod.; *Oleum Caryophyllorum, P. G.*; *Nelkenöl, Eugenol, G.*; *Essenza di garofani, It.*; *Esencia de clavo, Sp.*

This oil is obtained by distilling cloves with water, to which it is customary to add common salt, in order to raise the temperature of ebullition, and the water should be repeatedly distilled from the same cloves, in order completely to exhaust them. Scharling has found advantage from the application of superheated steam to the distillation of this oil. (*P. J.*, xi. 469.) It is essential also to use the same water over and over again, in order to avoid loss by the solution of the oil in the water. The product of good cloves is said to be about one-fifth or one-sixth of their weight. The oil was formerly brought from Holland or the East Indies, but since the introduction of the Cayenne cloves into our markets the reduced price and superior freshness of the drug have rendered the distillation of oil of cloves profitable in this country, and the best now sold is of domestic extraction. We have been informed that from seven to nine pounds of cloves yield to our distillers about one pound of the oil.

Properties.—Oil of cloves, when recently distilled, is very fluid, clear, and colorless, but becomes yellowish by exposure, and ultimately

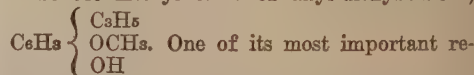

reddish brown. It has the odor of cloves, a hot, acrid, aromatic taste, and a slightly acid reaction. Its sp. gr. is variously stated at from 1.034 to 1.061, the latter being given by Bonastre as the sp. gr. of the rectified oil. "Specific gravity: 1.040 to 1.060 at 25° C. (77° F.). Soluble in an equal volume of alcohol, this solution being slightly acid to litmus paper; also soluble in about 2 volumes of 70 percent. alcohol. When shaken with an equal volume of a concentrated solution of potassium hydroxide, or of stronger ammonia water, it forms a semi-solid, yellowish mass. If 2 drops of the Oil be dissolved in 4 Cc. of alcohol, and a drop of ferric chloride T.S. added, a bright green color will be produced; and if the same test be made with a drop of diluted ferric chloride T.S., prepared by diluting the test solution with four times its volume of water, a blue color will be produced, which soon changes to yellow. If 1 Cc. of the Oil be shaken with 20 Cc. of hot water, the water should show a scarcely perceptible acid reaction to litmus paper. If, after cooling, the aqueous layer be passed through a wet filter, the clear filtrate should yield, with a drop of ferric chloride T.S., only a transient, grayish-green, but not a blue or violet color (absence of *phenol*)." *U. S.* "Colorless or pale yellow when recent, but gradually becoming reddish-brown, having the strong odor and taste of cloves. Specific gravity not below 1.050. An alcoholic solution yields a blue color with *test-solution of ferric chloride*. Shaken with its own volume of *strong solution of ammonia* it forms a semi-solid yellowish mass." *Br.*

Oil of cloves is one of the least volatile of the essential oils and requires for congelation a temperature from zero of Fahrenheit to -4°. It is completely soluble in alcohol, ether, and strong acetic acid. Nitric acid changes its color to a deep red, and converts it by the aid of heat into oxalic acid. The same change to red is produced by nitric acid on morphine, but in this case the red is followed by yellow, which does not happen with the oil of cloves. Besides, if to a solution of morphine with nitric acid a solution of chlorinated lime be added, and the mixture be exposed for some hours to the light, the solution of morphine will retain a straw color, while if oil of cloves be treated in the same manner the color disappears. (Haselden, *B. F. M. R.*, July, 1867, 265.) It is frequently adulterated with fixed oils, and sometimes with oil of pimenta and with copaiba. When pure, it sinks in distilled water. According to E. Scherer, these adulterations may sometimes be detected by attention to the specific gravity and the boiling point, pure oil of cloves varying in specific gravity from 1.03 to 1.06, and boiling at from 240° C. (464° F.) to 255° C. (491° F.). According to Zeller, its character of congealing entirely into a crystalline mass with the alcoholic solution of potassium hydroxide, losing at the same time its peculiar odor, affords a sufficient criterion of its purity.

This, however, while included among the official tests, is not sufficient, the percentage of eugenol as determined by the official assay being now a requirement. It appears to be indifferent in its rotatory effects on polarized light. (Buignet.)

Oil of cloves contains small amounts of *methyl alcohol* and *furfural*, but is mainly composed of an unsaturated phenol termed *eugenol*, which is now an official product (see *Eugenol*) and a sesquiterpene *caryophyllene*. The *U. S. Pharm.*, Eighth Revision, has introduced an assay process for the eugenol content, which is as follows:

Assay.—"Introduce into a flask with a long neck (graduated in tenths) 10 Cc. of the Oil of Cloves and 100 Cc. of potassium hydroxide T.S., and shake the mixture for five minutes. When the liquids have separated completely, add sufficient potassium hydroxide T.S. to raise the lower limit of the oily layer to the zero mark of the scale, and note the volume of the residual liquid, which should not measure more than 2 Cc., indicating the presence of at least 80 percent. of eugenol." *U. S.* *Eugenol*, $C_{10}H_{12}O_2$, has been shown to be the methyl ether of allyl-dioxybenzene,

actions is its conversion into *vanillin*. For this purpose it is boiled with acetic anhydride, whereby *aceteugenol* is formed, which, oxidized in weak acid solution by potassium permanganate, yields *acetovanillic acid*, and this with weak potassium hydroxide solution is changed into vanillin, which is then extracted by acidifying and shaking up with ether. (See also *Ph. Era*, 1887, 444.) For the estimation of eugenol in the form of its crystalline benzoyl compound, see *A. J. P.*, 1892, 26 and 508; also *Schim. Rep.*, April, 1892, 28. The characteristic aromatic odor of oil of cloves is due to *methyl-amyketone*, $\text{CH}_3\text{CO.C}_6\text{H}_{11}$, which has been isolated by the chemists of Schimmel & Co., and found to be present only in minute quantity. (*Ph. Rev.*, 1897, 115.)

Uses.—The medicinal effects of the oil are similar to those of cloves, and it is used for the same purposes, but its most common employment is as a corrigent of other medicines. It is a powerful local narcotic, and is often introduced into the cavity of a *carious aching tooth*. *Eugenol* has been given internally in doses of forty-five grains (3 Gm.) per day dissolved in alcohol and diluted in water; it probably resembles phenol in its physiological action, and has been used as an antiseptic and antipyretic. According to the experiments of Leubuscher (*W. M. Bl.*, 1889), it is a feeble local anæsthetic.

Dose, from two to six minims (0.12 to 0.4 Cc.).

OLEUM CHENOPODII. U. S.

OIL OF CHENOPODIUM [Oil of American Wormseed]

(ô'le-üm ghen-o-pô'dî-i)

"A volatile oil distilled from *Chenopodium anthelminticum* Linné (Fam. *Chenopodiaceæ*). It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." U. S.

Huile volatile d'Anserine vermifuge, *Fr. Cod.*; Essence de Chenopode anthelmintique, *Fr.*; Amerikanisches Wurmsamenöl, *Chenopodiumöl*, *G.*

This oil is peculiar to the United States. It is largely distilled in Maryland. (See *Chenopodium*.) It is of a light-yellow color when recently distilled, but becomes deeper yellow and even brownish by age. Its reaction is neutral. It has in a high degree the peculiar odor of the plant. "Specific gravity: about 0.965 to 0.985 at 25° C. (77° F.). It should be soluble in 5 volumes of 70 percent. alcohol. It is lævogyrate; the angle of rotation should not exceed —5° in a 100 Mm. tube, at a temperature of 25° C. (77° F.)." U. S. When freshly prepared, it has the sp. gr. 0.908, which, according to S. S. Garrigues, is increased by time to 0.960. A portion examined by him, which was of a brownish-yellow color, had the sp. gr. 0.959 at 61° F., boiled at 374° F., and was freely soluble in alcohol and ether. He found it to be composed of two distinct oils, separable by distillation; one of these has the formula $C_{10}H_{16}$, and is probably limonene; the other is heavier, and possesses the formula $C_{10}H_{16}O$. (*A. J. P.*, xxvi. 405.) Wormseed oil is used as an anthelmintic, given morning and evening for three or four days, and then followed by a brisk cathartic. Oil of wormseed has in various cases acted as a lethal poison. For fatal cases in children of three years of age, caused by a dose of one-half drachm, see *M. M. J.*, 1897, *T. G.*, xii; see also *B. M. S. J.*, xlv.

Dose, two to six minims (0.12 to 0.4 Cc.).

OLEUM CINNAMOMI. U. S., Br.

OIL OF CINNAMON [Oil of Cassia]

(ô'le-üm cîn-nā-mô'mî)

"A volatile oil distilled from Cassia Cinnamon (Fam. *Lauraceæ*), yielding, when assayed by the process given below, not less than 75 percent., by volume, of cinnamic aldehyde. It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." U. S. "The oil distilled from Cinnamon Bark." Br.

Oleum Cinnamomi Cassiæ; Oil of Chinese Cinnamon, Essence de Cannelle de Chine, Huile volatile de Cannelle, *Fr.*; Oleum Cinnamomi, *P. G.*; Zimmtöl, Zimmtkassienöl, *G.*; Essenza di Cannela, *It.*

There are two oils of cinnamon in commerce, one procured from the Ceylon cinnamon, the other from the Chinese cinnamon, and often distinguished by the name of *oil of cassia*.

There is no essential difference in the two oils, and that of the Chinese cinnamon, as much the cheaper and more abundant of the two, will probably continue to be generally employed, notwithstanding that the Ceylon product has the finer flavor.¹ The U. S. P. (8th Rev.) and the German Pharmacopœia recognize as oil of cinnamon only that obtained from cassia. The British Pharmacopœia and French Codex make Oil of Ceylon Cinnamon official.

Preparation.—Oil of cinnamon of Ceylon is distilled from inferior kinds of cinnamon, of insufficient value to pay the export duty. The following account of the method of extraction is given by Marshall. The bark, having been coarsely powdered, is macerated for two days in sea water, and then submitted to distillation. A light and a heavy oil come over with the water, the former of which separates in a few hours and floats upon the surface, the latter falls to the bottom of the receiver, and continues to be deposited for ten or twelve days. In future distillations, the saturated cinnamon water is employed with sea water to macerate the cinnamon. Eighty pounds of the freshly prepared bark yield about 2.5 ounces of the lighter oil, and 5.5 of the heavier. From the same quantity kept for several years in store, about half an ounce less of each oil is obtained. The two kinds are probably united in the oil of commerce. The oil is also distilled in Ceylon from the leaves, but the product is said to be too small to yield a fair profit. (*C. D.*, 1888.) The exportation of cinnamon chips from Ceylon has assumed large proportions, amounting in 1904 to 2,135,220 lbs. (*Schim. Rep.*, May, 1905.)

Properties.—Oil of Ceylon cinnamon is of a light-yellow color, becoming deeper by age, and ultimately red. Pereira stated that the London druggists redistilled the red oil, and thus obtained two pale-yellow oils, one lighter and the other heavier than water, with a loss of about 10 per cent. in the process. The oil has the flavor of cinnamon, and when undiluted is excessively hot and pungent. It is said sometimes to have a peppery taste, ascribable to an admixture of the leaves with the bark in the preparation of the oil. Oil of Ceylon cinnamon has "a slightly acid reaction. Sp. gr. about 1.040. It is readily soluble in alcohol. When cooled to —10° C. (14° F.), it remains clear, but at a lower temperature a solid portion separates from it." U. S. 1880. The

¹ Schimmel & Co. (*Schim. Rep.*, April, 1892) have shown that cinnamon leaf oil (from *Cinnamomum zeylanicum*), instead of being a thick, viscid oil, as frequently stated, is a bright, limpid oil, and is identical with the oil formerly exported from Ceylon in large quantities and thought to be produced from the roots of the cinnamon shrub. It has a sp. gr. of 1.05 to 1.06, and contains about 87 per cent. of eugenol and about 0.1 per cent. of cinnamic aldehyde; from this composition the cloves and cinnamon-like odor which it possesses may be understood. Saffrol is also present in small amounts. Von Romburgh (*Schim. Rep.*, Oct. 1892) has prepared the true cinnamon root oil, and finds it to contain large amounts of camphor, to which its odor is obviously due.

British Pharmacopœia 1898 recognizes oil of Ceylon cinnamon only, and gives the following description and tests: "Yellow when freshly distilled, but gradually becoming reddish; having the odor and taste of the bark. Specific gravity 1.025 to 1.035. 1 cubic centimetre dissolved in 5 cubic centimetres of alcohol (90 per cent.), and test-solution of ferric chloride added, should afford a pale green, but not a decided blue coloration (absence of cinnamon-leaf oil). If 10 cubic centimetres be well shaken with 50 cubic centimetres of a boiling 30 per cent. solution of sodium hydrogen sulphite, an oily layer separates, which, when cooled to 60° F. (15.5° C.), should not measure more than 5 cubic centimetres (absence of more than 50 per cent. of constituents other than aldehydes)." Br.

Chinese oil of cinnamon is imported from Canton and Singapore. It is pale yellow, becoming red with age. Its flavor is similar to that of the Ceylon oil, though inferior, and it commands a much lower price. It is officially described as "a yellowish or brownish liquid, becoming darker and thicker by age and exposure to the air, having the characteristic odor of cinnamon, and a sweetish, spicy, and burning taste. Specific gravity: 1.045 to 1.055 at 25° C. (77° F.). The Oil (or if it be dark, its distillate) should be optically almost inactive; it should not be more than one degree dextrogyrate or lævogyrat when viewed through a 100 Mm. tube. Soluble in 2 volumes of 70 per cent. alcohol. When shaken with a saturated solution of sodium bisulphite, it solidifies to a crystalline mass. If 4 drops of the Oil, contained in a test-tube, be cooled to 0° C. (32° F.), and then shaken with 4 drops of fuming nitric acid, crystalline needles or plates will be formed. If a portion of the oil be shaken with hydrogen sulphide T.S., it should not assume a dark color (absence of lead and copper). If 1 Cc. of the Oil be mixed with 3 Cc. of a mixture of 3 volumes of alcohol and 1 volume of water, a clear solution should result; and if to this solution there be gradually added 2 Cc. of a saturated solution of lead acetate in a mixture of 3 volumes of alcohol and 1 volume of water, no precipitate should be produced (absence of petroleum and of rosin)." U. S. The researches of Schimmel & Co. seem to show that the Chinese cassia oil of commerce is distilled from the leaves, leaf-stalks, and young twigs of the cassia plant,—probably with broken bark and various refuse products from the tree; also that much of the oil is adulterated with rosin and petroleum. (See official tests above.) The value of cassia oil depends upon the percentage of cinnamic aldehyde which it contains. (See *Cinnaldehydum* and the official assay of oil of cinnamon for the percentage of cinnamic aldehyde.) In a series of analyses made by Schimmel & Co. of oils having a specific gravity of 1.064 to 1.065, the proportion of aldehyde varied from 73.5 to 88 per cent. In the distillation by Schimmel & Co. the various portions of the cassia plant obtained from China yielded

the following results. 1. Cassia bark, *Cassia lignea* of commerce: yield of essential oil 1.5 per cent.; aldehyde in oil 92 per cent.; sp. gr. 1.035. 2. Cassia buds, *Flores Cassie* of commerce: yield of essential oil 1.550 per cent.; aldehyde in oil 80.4 per cent.; sp. gr. 1.026. 3. Cassia budsticks: yield of essential oil 1.64 per cent.; aldehyde in oil 92 per cent.; sp. gr. 1.046. 4. Cassia leaves, leaf-stalks, and young twigs mixed: yield of essential oil 0.77 per cent.; aldehyde in oil 93 per cent.; sp. gr. 1.055. Zeller states that oil of cassia is heavier, less liquid, and sooner rendered turbid by cold, and that in the Ceylon oil, iodine dissolves rapidly, with a considerable increase of heat, and the production of a tough residue, like an extract, while in oil of cassia the reaction is slow, quiet, and with little heat, and the residue is soft or liquid.

When exposed to the air, the oil absorbs oxygen, and is slowly converted into cinnamic acid, two distinct resins, and water. Of the two resins, one is soluble both in hot and in cold alcohol; the other readily in the former, but sparingly in the latter. *Cinnamic acid*, $C_9H_8O_2$, is colorless, crystalline, sourish, volatilizable, slightly soluble in water, readily dissolved by alcohol, and convertible by nitric acid with heat into benzoic acid. It is sometimes seen in crystals in oil of cinnamon which has been long kept. Like benzoic acid, it is said when swallowed to cause the elimination of hippuric acid by the urine. (*J. P. C.*, 3e sér., iii. 64.) It may be obtained by distilling the balsam of Tolu. Oil of cinnamon is almost wholly converted by nitric acid, slowly added, into a crystalline mass, producing a compound of the oil and the acid. These several facts are explained when it is found that oil of cinnamon contains from 75 to 90 per cent. of *cinnamic aldehyde*, C_9H_8O , which by moderate oxidation yields the corresponding cinnamic acid, $C_9H_8O_2$, but by more energetic oxidation yields benzoic acid, $C_7H_6O_2$. The oil has been produced artificially by Strecker from styrene, a derivative from styraz (see *Styraz*), and more recently from benzaldehyde and acetaldehyde, a mixture of which is saturated with hydrochloric acid gas, when a condensation takes place, as follows:

Ordinary sodium hydroxide will also bring about the reaction between the two aldehydes, and is to be preferred to hydrochloric acid for this purpose. The only other constituent of the cassia oil is cinnamyl acetate. Ceylon cinnamon oil, on the other hand, is said to contain some eugenol and phellandrene in addition to the cinnamic aldehyde.

Assay for Cinnamic Aldehyde. U. S. (8th Rev.)—"Introduce into a flask with a long graduated neck (cassia-flask), by means of a measuring-pipette, 10 Cc. of the Oil of Cinnamon, add 10 Cc. of a 30 percent. solution of sodium bisulphite, shake the flask, and heat it in a water-bath containing boiling water until the

contents are liquefied; add successive portions (10 Cc. each) of the bisulphite solution, shaking and heating as before, after each addition, until the flask is three-fourths filled. Continue to heat it in the water-bath until the odor of cinnamic aldehyde is no longer perceptible, cool the flask to about 25° C. (77° F.), and add enough of the bisulphite solution to raise the lower limit of the oily layer to the zero mark of the scale. The residual liquid should not measure more than 2.5 Cc., corresponding to at least 75 percent., by volume, of cinnamic aldehyde." *U. S.*

Oil of cinnamon is said to be frequently adulterated with oil of cloves, which, according to Ulex, cannot be detected by the odor or taste. Thus sophisticated, it is stated, on the same authority, to evolve a very acrid vapor when a drop is heated on a watch glass, to swell up and evolve red vapors if treated with fuming nitric acid, to remain liquid with concentrated potassium hydroxide, and to assume an indigo-blue color when ferrous chloride is added to its alcoholic solution, none of which reactions occur with pure oil.

Uses.—This oil has the cordial and carminative properties of cinnamon, without its astringency, and is much employed as an adjuvant to other medicines, the taste of which it corrects or conceals, while it conciliates the stomach. As a powerful local stimulant, it is sometimes prescribed in *gastrodynia*, *flatulent colic*, and *gastric debility*. Mitscherlich found six drachms to kill a moderate-sized dog in five hours, and two drachms one in forty hours. Inflammation and corrosion of the gastro-intestinal mucous membrane were observed after death.

Dose, one to three minims (0.06 to 0.2 Cc.).

"A volatile oil distilled from Copaiba. It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "The oil distilled from Copaiba." *Br.*

Oil of Copaiva; Oleum Balsami Copaivæ; Essence de Copahu, *Fr.*; Copaivaöl, *G.*

The oil constitutes from one-third to one-half or more of the copaiba. From one specimen of recent copaiba as much as 80 per cent. has been obtained. (*A. J. P.*, xxii. 289.) It is prepared largely by the application of steam heat. As it first comes over it is colorless, but the later product is of a fine greenish hue. By redistillation it may be rendered wholly colorless. It has the odor and taste of copaiba, a neutral reaction, boils at 252° to 256° C. (485.6° to 492.8° F.), solidifies, partly crystalline, at -15° F. (Gmelin), is soluble in ether and in an equal weight of absolute alcohol. The oil

consists chiefly of *caryophyllene*, a sesquiterpene, $C_{15}H_{24}$. "A colorless or pale yellow liquid, having the characteristic odor of copaiba, and an aromatic, slightly bitter, and pungent taste. Specific gravity: 0.895 to 0.905 at 25° C. (77° F.), increasing with age. It is lævogyrate. Soluble in 2 volumes of alcohol." *U. S.* "Colorless or pale yellow, with the odor and taste of copaiba. Specific gravity 0.900 to 0.910. It turns the plane of a ray of polarized light to the left, and is soluble in its own volume of *absolute alcohol* (distinction from African copaiba oil)." *Br.* From its want of oxygen, it answers even better than naphtha for preserving potassium, a fact first observed by Durand of Philadelphia. It dissolves sulphur and phosphorus.

Its effects on the system are those of copaiba. From the experiments of C. Mitscherlich, it is one of the least injurious of the volatile oils to the animal system, six drachms of it having been introduced into the stomach of a rabbit without causing death. Externally it produces much less irritation than does oil of turpentine. It may be used for the same purposes as copaiba.

Dose, five to fifteen minims (0.3 to 0.9 Cc.).

OLEUM CORIANDRI. *U. S.*, *Br.*

OIL OF CORIANDER

(ō'le-ūm cō-rī-ān'drī)

"A volatile oil distilled from Coriander. It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "The oil distilled from Coriander Fruit." *Br.*

Essence de Coriandre, *Fr.*; Korlanderöl, *G.*

This oil may be obtained by distillation with water from the bruised fruit in the manner directed in the *U. S. Pharm.* 1870 for volatile oils. The average yield of oil from coriander grown in different countries is from 0.2 to 1 per cent. It is pale yellow and colorless, and has the characteristic odor and taste of coriander, and a neutral reaction. Its sp. gr. is from 0.863 to 0.878 at 25° C. (77° F.), *U. S.*, and its boiling point 302° F. It is an oxygenated oil, consisting chiefly of a compound, *coriandrol*, $C_{10}H_{16}O$. According to Semmler (*Ber. d. Chem. Ges.*, 24, 206), coriandrol boils between 194° and 198° C., is optically dextrogyrate, and has a sp. gr. of 0.8679 at 20° C. Coriandrol is now known as dextrogyrate *linalool*. Schimmel & Co. (*Schim. Rep.*, April, 1892) have also found in coriander oil about 5 per cent. of *dextropinene*. The characteristic odorous principle or principles are unknown. It is officially described as "a colorless or slightly yellow liquid, having the characteristic, aromatic odor of coriander, and a warm, spicy taste. Specific gravity: 0.863 to 0.878 at 25° C. (77° F.). It should be soluble in 3 volumes of 70 percent. alcohol; also soluble in all proportions in 80

percent. and 90 percent. alcohol. It is dextrogyrate, the angle of rotation varying from $+7^\circ$ to $+14^\circ$ in a 100 Mm. tube, at a temperature of 25° C. (77° F.)." *U. S.* "Colorless or pale yellow, having the odor and flavor of the fruit. Specific gravity 0.870 to 0.885. If 1 cubic centimetre of the Oil be mixed with 3 cubic centimetres of alcohol (70 per cent.), a clear solution results (absence of oil of turpentine and added terpenes)." *Br.* Oil of coriander is extensively adulterated with colorless rectified oil of orange, which can be detected by its insolubility in 90 per cent. alcohol, in which pure coriander oil dissolves in every proportion; equal parts of oil of orange and 90 per cent. alcohol make a turbid mixture. (*A. J. P.*, Sept. 1878.) The oil has the medicinal properties of the fruit, and, like the aromatic oils generally, may be used to cover the taste or correct the nauseating or griping properties of other medicines. It has the great advantage of being more stable and retaining its agreeable odor longer than any other oil of its class.

Dose, three minims (0.2 Cc.).

Off. Prep.—Confectio Sennæ, *U. S.*; Spiritus Aurantii Compositus, *U. S.*; Syrupus Sennæ, *U. S.*, *Br.*

OLEUM CUBEÆ. U. S., Br.

OIL OF CUBE

(ō'le-ŭm cū-bē'bæ)

"A volatile oil distilled from Cube. It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "The oil distilled from Cubebs." *Br.*

Oleum Cubebærum; Oil of Cubebs; Huile volatile (Essence) de Cubèbe, *Fr.*; Kubebenöl, *G.*

The oil is obtained from cubeb by grinding the berries, and then distilling with water. From ten pounds Schönwald procured eleven ounces of oil, and this result very nearly coincides with the experiments of Christison, who obtained 7 per cent.; but by better methods of distillation 10 to 18 per cent. have been obtained. When recently distilled from the fruit, the oil is somewhat greenish, becoming yellowish by age, but when carefully redistilled it is colorless. It has the odor of cubeb, a warm, aromatic, camphoraceous taste, and a neutral reaction, is of a consistence approaching that of almond oil, is lighter than water, having the sp. gr. 0.920 (0.910 to 0.930, *Br.*), and when exposed to the air is said to thicken without losing its odor. It is soluble in an equal weight of alcohol. It is described in the *U. S. P.* (8th Rev.) as follows: "A colorless, pale green, or yellow liquid, having the characteristic odor of cubeb, and a warm, camphoraceous, aromatic taste. Specific gravity: 0.905 to 0.925 at 25° C. (77° F.). An alcoholic solution of Oil of Cubeb is neutral to litmus paper. It is lævogyrate, the angle of rotation varying from -25° to -40° in a 100 Mm. tube,

at a temperature of 25° C. (77° F.)." *U. S.* The oil consists chiefly of sesquiterpenes which distil over between 250° C. and 280° C., one of which is *cadinene*, $C_{15}H_{24}$, with some *dipentene*, and probably *pinene* or *camphene*. Upon standing, it sometimes deposits rhomboidal prismatic crystals of a stearopten. This camphor of cubeb has the formula $C_{15}H_{26}O$, is fusible at from 66° to 68° C., and volatilizes without change at from 148° to 150° C. According to Schmidt, it does not pre-exist in the cubeb, but is formed by the prolonged action of the air. (*J. P. C.*, Juin, 1875.) The oil has the aromatic properties of cubeb, but it is probably not the sole active ingredient, as it is much less pungent than the fluidextract or the oleoresin. It may, however, often be advantageously substituted for the powder, the dose to be gradually increased until its effects are obtained, or until it proves offensive to the stomach. It may be given suspended in water by means of sugar, in the form of emulsion, or enclosed in capsules of gelatin.

Dose, five to fifteen minims (0.3 to 0.9 Cc.).

OLEUM ERIGERONTIS. U. S.

OIL OF ERIGERON [Oil of Fleabane]

(ō'le-ŭm e-ri-gē-rōn'tis)

"A volatile oil distilled from the fresh, flowering herb of *Erigeron canadensis* Linné (Fam. *Compositæ*). It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

Oleum Erigerontis Canadensis, *U. S.* 1870; Oil of Canada Fleabane; Essence d'Erigeron, *Fr.*; Erigeronöl, *G.*

Oil of erigeron is limpid, of a light straw color, a peculiar, aromatic, persistent odor, and a characteristic taste. By exposure it becomes darker and thicker. Its reaction is neutral. Its sp. gr. is about 0.850, increasing with age (0.855 to 0.890, *Schim. Rep.*). It consists chiefly of dextrogyrate *limonene*, together with some *terpineol*. (*A. J. P.*, 1893, 420.) It is officially described as "a pale yellow, limpid liquid, rapidly becoming darker and thicker by age and exposure to the air, having a peculiar, aromatic, persistent odor, and an aromatic, slightly pungent taste. Specific gravity: 0.845 to 0.865 at 25° C. (77° F.). Soluble in an equal volume of alcohol (distinction from oil of fireweed derived from *Erechthites hieracifolia* Rafinesque (Fam. *Compositæ*) and from oil of turpentine). It is dextrogyrate, the angle of rotation being about $+50^\circ$ in a 100 Mm. tube, at a temperature of 25° C. (77° F.)." *U. S.* When distilled without water, it comes over colorless, and a little resinous matter is left behind, probably resulting from the oxidation of one or both of the constituent oils. It is readily soluble in alcohol. It is slowly reddened by potassium hydroxide, combines with iodine without ex-

plosion, is instantly decomposed by sulphuric acid, and is acted on by strong nitric acid, slowly at ordinary temperatures, but with heat explosively. (Procter, *A. J. P.*, xxvi. 502.) The plant yields 0.2 to 0.4 per cent. of oil. When exposed to the air, the oil darkens and rapidly resinifies. For an account of the difference in properties between this oil and that from *Erechthites hieracifolia*, see a paper by Albert M. Todd, *A. J. P.*, 1887, p. 302.

It was first brought into notice by the so-called eclectic physicians, who use it in *diarrhœa*, *dysentery*, and the *hemorrhages*, and certainly it is a very valuable remedy in *hæmoptysis* when there is no fever or other marked evidence of constitutional irritation. As long ago as 1854 it was commended highly by E. Wilson in *uterine hemorrhage*, while J. W. Moorman speaks of it most highly in all forms of hemorrhage, in *diarrhœa of debility*, in *dysentery* after sufficient evacuation of the stomach and bowels, and especially in *hemorrhage from the bowels during typhoid fever*. (*Am. J. M. S.*, Oct. 1865, p. 396.) It probably acts like the oil of turpentine as a hæmostatic, but is much less irritant and stimulating.

Dose, ten minims to half a fluidrachm (0.6 to 1.8 Cc.), repeated every hour or two.

OLEUM EUCALYPTI. U. S., Br.

OIL OF EUCALYPTUS

(ô'le-ûm eû-ca-lyp'tî)

"A volatile oil distilled from the fresh leaves of *Eucalyptus*, rectified by steam distillation, and yielding, when assayed by the process given below, not less than 50 percent., by volume, of cineol (*eucalyptol*). It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "The oil distilled from the fresh leaves of *Eucalyptus Globulus*, *Labill.*, and other species of *Eucalyptus*." *Br.*

Oil of *Eucalyptus Globulus*; Huile volatile (Essence) de *Eucalyptus*, *Fr. Cod.*; *Eucalyptusöl*, *G.*; *Esencia de eucalipto*, *Sp.*

Various species of the genus *Eucalyptus*, grown in Australia and Algeria, yield volatile oils in sufficient quantity to be commercial products. Probably the most important of these plants are the *E. amygdalina*, whose volatile oil was at one time supposed to be destitute of *eucalyptol*, but has been shown by Gilde-meister (*Ph. Ztg.*, 1888) to contain that principle, and to have *phellandrene* for its chief constituent; *E. odorata*, the oil of which is affirmed to be extremely rich in *eucalyptol*, but to contain no *phellandrene*; and *E. oleosa*, the oil of which is stated to be so rich in *eucalyptol* that at a low temperature it becomes pasty. Under these circumstances the revisers of the *U. S. Pharm.* acted very properly in rejecting all those oils which contain enough *phellandrene* to respond to the sodium nitrite

test. Oil of *eucalyptus* is officially described as "a colorless or pale yellow liquid, having a characteristic, aromatic, somewhat camphoraceous odor, and a pungent, spicy, and cooling taste. Specific gravity: 0.905 to 0.925 at 25° C. (77° F.). Soluble, in all proportions, in alcohol; also soluble in 3 volumes of 70 percent. alcohol. Its alcoholic solution should be neutral to litmus paper. It is dextrogyrate, the angle of rotation being not more than +10° in a 100 Mm. tube, at a temperature of 25° C. (77° F.). If 2 Cc. of the oil be mixed with 4 Cc. of glacial acetic acid, and 3 Cc. of a saturated, aqueous solution of sodium nitrite be gradually added, the mixture, when gently stirred, should not form crystals of *phellandrene nitrite* (absence of *eucalyptus* oils containing much *phellandrene*)." *U. S.* "Specific gravity 0.910 to 0.930. It should not rotate the plane of a ray of polarized light more than 10° in either direction in a tube 100 millimetres long, and it should become semi-solid on being stirred, when cold, with a third or half its volume of phosphoric acid of commerce of specific gravity 1.750 (presence of a due proportion of cineol). If to 1 cubic centimetre of the Oil there be added 2 cubic centimetres of *glacial acetic acid* and 2 cubic centimetres of a saturated aqueous solution of *sodium nitrite*, the mixture, when gently stirred, should not form a crystalline mass (exclusion of *eucalyptus* oils containing much *phellandrene*)." *Br.*

Assay for Cineol.—"Introduce into a beaker a solution prepared by dissolving 10 Cc. of Oil of *Eucalyptus* in 50 Cc. of purified petroleum benzin; immerse the beaker in a freezing mixture and add phosphoric acid, drop by drop, with constant stirring, until the white magma of cineol phosphate formed, begins to assume a yellowish or pinkish tint; then transfer the magma to a force filter, wash it with cold purified petroleum benzin, and then dry it by pressure between two porous plates. Transfer the precipitate (cineol phosphate) to a narrow graduated cylinder, and add warm water, which will cause separation of the cineol. The volume, in cubic centimeters, of the separated oil, multiplied by 10, represents the volume percent. of cineol (*eucalyptol*). This should correspond to the properties and tests given under *Eucalyptol*." *U. S.* *Eudesmol*, $\text{C}_{10}\text{H}_{16}\text{O}$ (possibly a ketone), is the name given to a crystalline camphor obtained from the oil from *E. piperita*; H. G. Smith and R. T. Baker isolated this product, and later H. G. Smith read a paper upon it before the Royal Society of New South Wales. It proved to be isomeric with camphor, but chemically it is shown to have its oxygen atom combined in a different way. Power has modified the test for *phellandrene* so as to make it more delicate. According to his directions, 1 Cc. of the oil is mixed with 5 Cc. of petroleum benzin, 1 or 2 Cc. of a concentrated solution of sodium nitrite added, and subsequently glacial

acetic acid added, a drop or two at a time, with vigorous agitation after each addition. If phellandrene is present in any considerable amount, its crystalline nitrosite, $C_{10}H_{16}(NO)NO_2$, will separate from the benzin solution. It contains *cymene*, $C_{10}H_{14}$, *pinene*, $C_{10}H_{16}$, and *eucalyptol* (or *cineol*), $C_{10}H_{18}O$. Schimmel & Co. also state (*Ber. d. Chem. Ges.*, April, 1888) that they have obtained several of the aldehydes of the fatty series, notably *valeraldehyde*, and probably *butyraldehyde* and *capronaldehyde*, in their distillation of the oil from *Eucalyptus Globulus*. The medicinal value of the oil of eucalyptus has been believed to depend upon the eucalyptol present in it, but we have no definite knowledge as to the physiological action of phellandrene, and it may well be that the phellandrene oils act similarly to the eucalyptol. As eucalyptol is now official, it may be preferred by the practitioner as being of definite strength and character, the percentage of eucalyptol even in the best oils varying considerably.

Dose, ten to fifteen minims (0.6 to 0.9 Cc.), best administered in capsules.

Off. Prep.—Unguentum Eucalypti, *Br.*

OLEUM FœNICULI. U. S.

OIL OF FENNEL

(ô'le-üm fœ-nic'û-li)

"A volatile oil distilled from Fennel. It should be kept in well-stoppered, amber-colored bottles, in a cool place, and, if it has partly or wholly solidified, it should be completely liquefied by warming and then well shaken before being dispensed." *U. S.*

Huile volatile de Fenouil, *Fr. Cod.*; Essence de Fenouil, *Fr.*; Oleum Fœniculi, *P. G.*; Fenchelöl, *G.*

Fennel seeds yield about 2.5 per cent., or, according to Zeller, from 3.4 to 3.8 per cent., of oil. That used in this country is imported. "A colorless or pale yellow liquid, having the characteristic, aromatic odor of fennel, and a sweetish, mild, and spicy taste. Specific gravity: 0.953 to 0.973 at 25° C. (77° F.). Soluble in an equal volume of alcohol, the solution being neutral to litmus paper; also soluble in 10 volumes or less of 80 percent. alcohol. An alcoholic solution of Oil of Fennel is neutral to litmus paper, and is not colored by the addition of a drop of ferric chloride T.S. (absence of some volatile oils containing *phenols*). When tested according to the following methods, the congealing point of Oil of Fennel should not be below 5° C. (41° F.). Transfer about 10 Cc. of the Oil to a test-tube placed in a freezing mixture; insert a thermometer at once into the oil, and allow it to remain undisturbed until its temperature has fallen to about -5° C. (23° F.). Induce crystallization either by rubbing the inner wall of the test-tube with the thermometer or by the addition of a particle of solid anethol, and

stir continuously during the solidification of the Oil. The highest temperature reached during the crystallization is regarded as the congealing point." *U. S.* It congeals below 50° F. into a crystalline mass, separable by pressure into a solid and a liquid portion, the former heavier than water, and less volatile than the latter, which rises first when the oil is distilled. It contains *d-pinene*, *phellandrene*, *dipentene*, *fenchone*, $C_{10}H_{16}O$ (a liquid ketone), and *anethol*, $C_{10}H_{12}O$ (a phenol-ether forming a white solid melting at 21° C.), (see *Oleum Anisi*), the latter usually in amounts of about 60 per cent. (*Pover's Catalogue of Essential Oils*, 1894.) *Schimmel's Report* for April, 1897, mentions *limonene* as also at times present as a constituent. Umney finds that Japanese oil contains about 75 per cent. of anethol and 10 per cent. of fenchone, besides terpenes. (*Proc. A. Ph. A.*, 1897, 516.) There is reason to believe that much of the commercial oil is adulterated with oil from which the anethol or crystalline constituent has been separated; the official solidifying point not below 5° C. (41° F.) should be required. Flückiger states (*Pharm. Chem.*, 2d ed., 1888, 422) that it contains more hydrocarbon than oil of anise, and notably that from Nîmes, in Southern France, contains much less anethol, and hence has a milder and sweeter taste. As found in commerce, therefore, the oil of fennel is not uniform, and a specimen examined by Montgomery did not congeal at -5.5° C. (22° F.). (See *Oleum Anisi*.) It is slightly dextrogyrate.

Dose, three to five minims (0.2 to 0.3 Cc.).

Off. Prep.—Aqua Fœniculi, *U. S.*; Pulvis Glycyrrhizæ Compositus, *U. S.*; Spiritus Juniperi Compositus, *U. S.*

OLEUM GAULTHERIÆ. U. S., *Br. Add.*

OIL OF GAULTHERIA [Oil of Wintergreen]

(ô'le-üm gaul-thê'rî-æ)

"A volatile oil distilled from the leaves of *Gaultheria procumbens* Linné (Fam. *Ericaceæ*), rectified, if necessary, by steam distillation. It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

Oil of Teaberry, Oil of Partridge-berry; Huile volatile (Essence) de Winter-green, *Fr. Cod.*; Essence de Gaulthérie, *Fr.*; Wintergründöl, *Bergtheöl*, *G.*

The volatile oil of gaultheria is largely obtained in the United States by distillation of the plant. It probably does not exist in the plant, but is formed by a reaction between water and a neutral principle analogous to amygdalin, to which Procter has given the name of *gaultherin*. (*A. J. P.*, xv.) This substance, which was called by Schneegans *bétulase*, probably exists in all the numerous plants which yield methyl salicylate on distillation. The oil occurs in various of our native plants, and has been detected in *Polygala paucifolia*, *Spiræa Ulmaria*, *Spiræa lobata*, and

Gaultheria chiogenes. T. E. de Vrij found it in considerable proportion in the *Gaultheria leucocarpa* and *G. punctata*, plants which are abundant in the volcanic regions of Java (A. J. P., 1879); while Bourquelot (C. R. S. B., iii. 1896) detected it in *Monotropa Hypopitys*, in *Polygala Senega*, and in other species of *Polygala*. (See also A. J. P., 1898, 412.) Much of the commercial oil of wintergreen is obtained from *Betula lenta*.

Oil of gaultheria when freshly redistilled is nearly colorless, but as found in commerce has a brownish-yellow or reddish color.¹ "A colorless or almost colorless liquid, having a characteristic, strongly aromatic odor, and a sweetish, warm, and aromatic taste. Specific gravity: 1.172 to 1.180 at 25° C. (77° F.). Boiling point: 218° to 221° C. (424.4° to 429.8° F.). It is slightly levogyrate, up to -1° in a 100 Mm. tube, at 25° C. (77° F.). In other respects it has the same properties as, and conforms to the reactions and tests given under, *Methylis Salicylas*." U. S. It is stated to have been largely adulterated with chloroform. This and other impurities are to be detected by a comparison of the specific gravities and boiling points, or by fractional distillation. It is readily soluble in alcohol. When heated to about 80° C. (176° F.), the oil should not yield a colorless distillate having the characteristics of chloroform or of alcohol (A. J. P., 1873, p. 521). Another distinguishing property is that in aqueous solution it gives a purple color with ferric salts. Oil of sassafras may be detected by the separation of a deep-red resinous mass on treatment with nitric

¹ *Distillation of Oil of Gaultheria*.—Isaac Edward Leonard states that oil of wintergreen, first made in Luzerne County, Pa., in 1863, has since been distilled there in large quantities. The entire plant is employed, and it gives the greatest yield during the months of July and August.

The still is generally a wooden box, about eight feet long, four feet wide, four feet high, with a copper bottom and stayed with bolts. The head of the still is copper, and connecting with this is a circular worm of the same material or of tin, placed in a barrel. The still being filled with wintergreen to within about twelve inches of the top, a sufficient quantity of water is added, and this is allowed to macerate from ten to twelve hours. The fire being started, the distillation commences, and continues for about eight hours; but during the first two or three hours ninety per cent. of the oil has passed over. For collecting the distillate, most of the distillers use a wide-mouthed bottle, fitted with a large cork having two holes. A small funnel is put into one of the holes, so that the beak is below the shoulder of the receiving vessel, and connected with the other hole is a suitable pipe forming an outlet. The oil and the water separate, the oil going to the bottom, and the water passes into a larger receptacle, where it is reserved for a subsequent operation (cobobation).

Occasionally the oil is very highly colored, and the wholesale dealers have three ways of "cleaning" it—redistillation, filtration, and decolorization. The oil to be decolorized is put into a bottle, crystals of citric acid are added, and the whole is allowed to stand, agitating occasionally, until the oil is colorless, or nearly so. On experimenting with nine quarts of wintergreen fruit, the author found it contained one and one-half drachms of oil. In experimental distillation he found that the lower specific gravity is due to the separating of the oil from the water too quickly, and that the higher specific gravity is obtained by letting the distillate stand for twenty-four to forty-eight hours before separating the oil from the water. (A. J. P., 1884, p. 264.)

acid in the cold. Japanese oil of camphor and other light volatile oils used as adulterants can be detected by simply dropping the suspected oil in water; if pure, it sinks in a few seconds; if adulterated, some minutes are required. Procter proved that oil of gaultheria has acid properties and contains *salicylic acid*. (See *Salix*.) Cahours confirmed this, and stated that one-tenth of the oil consists of a peculiar hydrocarbon, which he called *gaultherilene*, and the remaining nine-tenths of *methyl salicylate* or the methyl ester of salicylic acid, $\text{CH}_3\text{C}_7\text{H}_5\text{O}_2$. A product having the properties of the latter compound was obtained by distilling a mixture of methyl alcohol, salicylic acid, and sulphuric acid. (A. J. P., xiv. 211, xv. 241.) Trimble and Schroeter (*Ibid.*, 1889, 398) found that the amount of the hydrocarbon *gaultherilene* was much less than that stated by Cahours,—in fact, only 0.3 per cent. By analysis and vapor density determination they fixed its formula as $\text{C}_{15}\text{H}_{24}$, but they state that it may consist of a solid and a liquid portion. Power and Kleber (*Fritzsche Bros. Circ.*, No. 7) assert that this hydrocarbon belongs to the paraffin series, and state that it is probably *triacontane*, $\text{C}_{30}\text{H}_{62}$. They also find in the oil an aldehyde or ketone, with an odor like *œnanthol* aldehyde, an apparently secondary alcohol, $\text{C}_8\text{H}_{18}\text{O}$, and an ester, $\text{C}_{14}\text{H}_{24}\text{O}_2$. To the alcohol and the ester are attributed the characteristic odor of the oil. True oil of gaultheria contains about 99 per cent. of methyl salicylate. *Artificial oil of wintergreen* is now extensively manufactured and used instead of the natural oil. For a process by H. T. Thayer, see A. J. P., 1895, 244. (See *Methylis Salicylas*, p. 778.)

Uses.—Oil of gaultheria is largely used on account of its pleasant flavor; it may, however, be employed as a substitute for salicylic acid with excellent results. One hundred and sixty-nine grains of the oil contain one hundred and fifty-two grains of methyl salicylate, and are therefore equivalent to one hundred and thirty-eight grains of salicylic acid. An elaborate research by H. C. Wood (*T. G.*, vol. ii. p. 76) proved that this drug acts physiologically like salicylic acid. When taken in moderate amounts it is, like that acid, broken up in the system and eliminated as salicyluric acid, etc. It is capable of causing fatal poisoning. Half an ounce produced in a boy severe vomiting, purging, epigastric pain, hot skin, frequent pulse, slow and labored respiration, and dulness of hearing; the boy recovered. (*Medical Examiner*, N. S., viii.) Two ounces caused in an adult, intense sweating, violent uncheckable diarrhœa, rapid and very irritable pulse, intense itching, and death from exhaustion in forty-one hours. (N. Y. M. R., vol. lviii.) A woman survived after having taken half an ounce (N. Y. M. J., 1875), but the same amount has caused death (*Ibid.*, 1867).

Dose, fifteen to thirty minims (0.9 to 1.8 Cc.).

Off. Prep.—Emulsum Olei Morrhuæ, *U. S.*; Emulsum Olei Morrhuæ cum Hypophosphitibus, *U. S.*; Liquor Antisepticus, *U. S.*; Spiritus Gaultheriæ, *U. S.*; Syrupus Sarsaparillæ Compositus, *U. S.*

OLEUM GOSSYPII SEMINIS. *U. S.*

COTTON SEED OIL

(ô'le-ûm gôs-sÿp'i-i sêm'i-nis)

"A fixed oil expressed from the seeds of *Gossypium herbaceum* Linné, or of other species of *Gossypium* (Fam. *Malvaceæ*), and subsequently purified. It should be kept in well-closed containers." *U. S.*

Oleum Gossypii: Cotton Oil; Huile de Semences de cotonnier, *Fr.*; Baumwollsamönl, Cottonöl, *G.*

This fixed oil has no other medicinal properties than those of a bland neutral oil, and has been introduced especially on account of its use in official liniments. The amount of cotton seed crushed in 1905, according to the census report, was 3,308,930 tons, and the production of crude cotton seed oil amounted to 132,051,801 gallons, valued at \$31,011,905. Of this production, about one-fourth goes into the manufacture of "compound lard" and "cottolene," a still larger amount is exported as cotton seed oil, and the remainder is used in admixture with drying oils and for soap stock. The oil cake is largely exported to England, where it is used as food for cattle, and the oil to France, Italy, and other olive growing countries of Europe, whence much of it returns to us mixed with olive oil. The exportation of cotton seed oil for 1903 amounted to 35,642,994 gallons, valued at \$14,211,244; for 1904 to 29,014,417 gallons, valued at \$10,717,280. For a description of the process of extraction, see *A. J. P.*, 1896, 42; also 1898, 497.

This oil is obtained by expression from the seeds previously deprived of their shells. In this state they yield two gallons of oil to the bushel. As first obtained, it is thick and turbid, but it deposits a portion of its impurities on standing. Besides this crude oil, there are three varieties in commerce, more or less purified, recognized as the *clarified*, the *refined*, and the *winter bleached*. The last mentioned is of a pale straw-color, a mild peculiar odor, and a bland sweetish taste, not unlike that of almond oil. The oil is used in the preparation of woolen cloth and morocco leather, and for oiling machinery. It has been found to be an excellent substitute for almond and olive oils in most pharmaceutical preparations in which they are employed, but it does not answer well in the formation of lead plaster. Citrine ointment carefully prepared with it, too great heat being avoided, retains a rich orange color and proper unctuous consistence.

Properties.—It is officially described as "a pale yellow, oily liquid, without odor, and having a bland, nut-like taste. Specific gravity: 0.915 to 0.921 at 25° C. (77° F.). Very spar-

ingly soluble in alcohol, but readily soluble in ether, chloroform, or carbon disulphide. On cooling the Oil to a temperature below 12° C. (53.6° F.), particles of solid fat will separate. At about 0° to -5° C. (32° to 23° F.), the Oil becomes nearly or quite solid. If sulphuric acid (specific gravity 1.6 to 1.7) be added to the Oil, preferably diluted with carbon disulphide, a reddish-brown color is rapidly produced. If 6 Gm. of the Oil be thoroughly shaken in a test-tube for about ten minutes with a mixture of 1.5 Gm. of nitric acid and 0.5 Gm. of water, then heated in a bath of boiling water for not more than fifteen minutes, the Oil will assume an orange or reddish-brown color, and after standing for twelve hours at the ordinary temperature, will form a semi-solid mass. If 5 Cc. of the Oil be thoroughly shaken in a test-tube with 5 Cc. of an alcoholic solution of silver nitrate (made by dissolving 0.1 Gm. of silver nitrate in 10 Cc. of alcohol and adding 2 drops of nitric acid), and if the mixture be heated for about five minutes on a water-bath, the Oil will assume a red or reddish-brown color. If 2 Cc. of the Oil be mixed in a test-tube with 2 Cc. of equal volumes of amyl alcohol and carbon disulphide containing 1 percent. of sulphur in solution, and the test-tube be immersed to one-third or one-half its depth in boiling salt water, a red color will develop in from ten to fifteen minutes. Cotton Seed Oil saponified by alcoholic potassium hydroxide T.S. should show a saponification value of from 191 to 196 (see PART III, Test No. 99). If 0.3 Gm. of Cotton Seed Oil be dissolved in 10 Cc. of chloroform, in a 250 Cc. bottle or flask, and 25 Cc. of a mixture of equal volumes of alcoholic iodine T.S. and alcoholic mercuric chloride T.S. added, and if, after standing for four hours protected from the light, 20 Cc. of potassium iodide T.S. be introduced, and the mixture diluted with 50 Cc. of water, on titrating the excess of iodine with tenth-normal sodium thiosulphate V.S. an iodine value of not less than 102 nor more than 108 should be obtained (see PART III, Test No. 51)." *U. S.*

Cotton seed oil has been examined by A. Adriani (*Chem. News*, Jan. 7, 1865, p. 5). The product of the expressed seeds is from 15 to 18 per cent. In its impure state it is dark reddish-brown, not quite clear, and contaminated with mucilage and albumen. When boiled with an alkaline solution, crude cotton seed oil is saponified, and the resultant soap rapidly oxidizes on exposure to air, with production of a fine purple or violet-blue coloration.¹ This reaction is characteristic of crude

¹ "Cotton seed blue" is stated by Kuhlmann to have the composition $C_{27}H_{24}O_4$. It is amorphous, readily destroyed by oxidizing agents, insoluble in water, diluted acids, and alkalis, soluble in alcohol and ether. The unoxidized coloring matter of cotton seed oil has also been investigated by J. Longmore, who finds it to be a pungent, golden-yellow product, which dyes fabrics very well, the color being perfectly fast on wool and silk. (*Allen, Com. Org. Anal.*, 2d ed., 1887, p. 113.)

cotton seed oil. The sp. gr. of the crude oil varies from 0.928 to 0.930; that of the refined oil, from 0.922 to 0.926.

The oil is clarified by first boiling it with water, to separate the mucilage, and then heating it with a weak solution of sodium hydroxide, which combines with the coloring matter and saponifies a part of the oil. The mixture becomes filled with black flocks, which deposit on standing and leave the oil but slightly colored. The loss in refining is usually from 4 to 7½ per cent., but occasionally amounts to 12 or 15. As this oil is much used for adulterating olive oil, tests to distinguish it are very desirable. The tests most depended upon are those with an alcoholic solution of silver nitrate (Beechi's test) and with a mixed solution of amyl alcohol and carbon disulphide containing 1 per cent. of dissolved sulphur (Halphen's test). These are given in the official tests.

Dose, two to six fluidrachms (7.5 to 22.5 Cc.).

Off. Prep.—Linimentum Ammoniacæ, U. S.; Linimentum Camphoræ, U. S.

OLEUM HEDEOMÆ. U. S.

OIL OF HEDEOMA [Oil of Pennyroyal]

(õ'le-üm hêd-ê-õ'mæ)

"A volatile oil distilled from the leaves and flowering tops of Hedeoma. It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." U. S.

Essence de Hédéoma, Essence de Pullot américaine, Fr.; Pennyroyalöl, Amerikanisches Pöfelöl, G.

This oil, though analogous in properties to the oil of European pennyroyal, is derived from a distinct plant (*Hedeoma pulegioides*), peculiar to North America. "A pale yellow, limpid liquid, having a characteristic, pungent, mint-like odor and taste. Specific gravity: 0.920 to 0.935 at 25° C. (77° F.). It should form a clear solution with 2 volumes or more of 70 percent. alcohol. It is dextrogyrate, the angle of rotation varying from about +18° to +22° in a 100 Mm. tube, at a temperature of 25° C. (77° F.)." U. S. Its chemical composition was investigated by E. Kremers (A. J. P., 1887, p. 535) and F. W. Franz (Ibid., 1888, p. 161). Each of them found a body of the composition C₁₀H₁₆O, boiling at 217° to 218° C. (constituting, according to Franz, about 33 per cent. of the oil). For this the name *hedeomol* was proposed. Franz also found a body of the composition C₁₀H₁₄O, boiling at 220° to 225° C., and constituting 12 per cent. of the oil; likewise a body of the composition C₈H₁₆O, boiling at 165° to 170° C., and constituting about 0.7 per cent. of the oil. Both investigators found *formic* and *acetic acids*, and Kremers considers *isoeheptic acid* also to be present. Beckmann and Pleissner (Ann. Ch. Ph., 262, p. 1) found in American as well as in Spanish and Algerian

pennyroyal oil a ketone, C₁₀H₁₆O, to which they gave the name of *pulegone*. This compound forms with hydroxylamine an oxime, C₁₀H₁₅NO.H.H₂O, crystallizing in beautiful needles melting at 157° C., and with hydrogen bromide a crystalline compound melting at 40.5° C. The two compounds of the formula C₁₀H₁₆O, discovered by Kremers (Ph. Rund., ix. p. 130), are also ketones and yield corresponding oximes. The oil may be used as a remedy in flatulent colic and sick stomach, to correct the operation of nauseating or griping medicines. It is also much employed as a domestic remedy in *amenorrhœa*.

Dose, two to ten minims (0.12 to 0.6 Cc.).

OLEUM JUNIPERI. U. S., Br.

OIL OF JUNIPER

(õ'le-üm jû-nîp'ê-rî)

"A volatile oil distilled from the fruit of *Juniperus communis* Linné (Fam. Conifera). It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." U. S. "The oil distilled from the full-grown unripe fruit of *Juniperus communis*, Linn." Br.

Oleum Fructus (vel Baccæ) Juniperi; Oil of Juniper Berries; Huile volatile (Essence) de Genièvre, Fr.; Oleum Juniperi, P. G.; Wachholderöl, Wachholderbeeröl, G.; Essenza di ginepro, It.

The proportion of oil which juniper berries afford is stated very differently by different authors. Trommsdorff obtained 1 per cent. The highest quantity given in the table of Recluz is 2.34, the lowest 0.31 per cent. Zeller gives as the product of the fresh ripe fruit 1.3 per cent., of that a year old 0.86 per cent. The berries are most productive when bruised. The oil of juniper consumed in this country is brought from Europe, and is believed to be procured chiefly from the tops of the plant, being sold for a price which is altogether incompatible with the idea that it is prepared from the fruit alone. "A colorless, faintly green or yellow liquid, having the characteristic odor of juniper, and a warm, aromatic, somewhat terebinthinate and slightly bitter taste. Specific gravity: 0.860 to 0.880 at 25° C. (77° F.). Soluble in 10 volumes of 90 percent. alcohol." U. S. "Specific gravity 0.865 to 0.890. The Oil is soluble, with slight turbidity, in 4 times its own volume of a mixture of equal parts of *absolute alcohol* and *alcohol* (90 per cent.)." Br. According to Flückiger (Pharm. Chem., 2d ed., 1888, 402), it is composed essentially of two hydrocarbons, the more abundant of which, boiling at 160° C., has been shown by Wallach to be *pinene*, C₁₀H₁₆. Above 175° C. another oil is obtained, which seems to be *cadinene*, C₁₅H₂₄. It also contains a small amount of an ester to which the peculiar juniper-like odor and taste was supposed to be due, but this cannot be the case, as the odor persists after the complete

saponification of the small amount of ester. *Juniper camphor* is also present, its melting point is 165° C. to 166° C. Oil of turpentine is often fraudulently added, but may be detected by the specific gravity of the mixture being less than that of the unadulterated oil of juniper.

The oil is stimulant, carminative, and diuretic, and is very useful in combination with other remedies in debilitated *dropsical* cases. To it Holland gin owes its peculiar flavor and diuretic power.

Dose, five to fifteen minims (0.3 to 0.9 Cc.), which may be considerably increased.¹

Off. Prep.—*Spiritus Juniperi, U. S., Br.; Spiritus Juniperi Compositus, U. S.*

OLEUM LAVANDULÆ. Br.

OIL OF LAVENDER

(ô'le-üm la-văn'dù-læ)

"The oil distilled from the flowers of *Lavandula vera*, DC." *Br.*

Hulle volatile de Lavande officinale, *Fr. Cod.*; Essence de Lavande, *Fr.*; Oleum Lavandulæ, *P. G.*; Lavandöl, *G.*; Essenza di lavanda, *It.*; Esencia de espliego, *Sp.*

This oil is usually distilled from the flowers and flower stems conjointly, though of finer quality when obtained from the former exclusively. (See the next article, *Oleum Lavandulæ Florum*.) Dried lavender flowers are said to yield from 1 to 1.5 per cent. of oil. According to Zeller, the fresh flowers yield 1.03, the dried 4.3, the whole fresh herb in flower 0.76 per cent. It is stated that the lavender produced by an acre of ground under cultivation will yield from 10 to 12 pounds of the oil. (*P. J.*, 1864, p. 257.) The oil is very fluid, of a lemon-yellow color, with the fragrance of the flowers and an aromatic, burning taste. That met with in commerce has the sp. gr. 0.898 at 68° F., which is reduced to 0.877 by rectification (Berzelius), or 0.886 (Buignet). It is lævogyrate. According to Brande, the sp. gr. of the oil obtained from the whole herb is 0.9206. Alcohol of 0.830 dissolves oil of lavender in all proportions, that of 0.877 only 42 per cent. (Berzelius.) Proust states that when allowed to stand in imperfectly stoppered bottles it lets fall a crystalline deposit, which often amounts to one-fourth of its weight. This has been found by Dumas to have the same point of

volatilization and the same composition as true camphor, but to differ in the total want of rotatory power. It is said that the portion of oil first distilled is most fragrant, and is often kept separate, and sold at a higher price. "Pale yellow or nearly colorless, with the fragrant odor of the flowers, and a pungent bitter taste. Specific gravity not below 0.885. It should dissolve in 3 times its volume of alcohol (70 per cent.)." *Br.* The principal constituent is an alcohol, $C_{10}H_{18}O$, identical with the *linalool* discovered by Semmler in linaloe oil. This alcohol boils at from 197° to 199° C., and has a sp. gr. of 0.869 at 20° C. Besides linalool, lavender oil contains *linalyl acetate* (from 30 to 45 per cent. in the oil from French flowers, and from 7 to 10 per cent. in the oil from English flowers), the *butyric ester* of the same alcohol, *geraniol*, a very small amount of *cincol*, and traces of a sesquiterpene.

Oil of Spike is procured from the broad leaved variety of lavender which grows wild in Europe, the *Lavandula Spica* of De Cavanilles. Its odor is less fragrant than that of common oil of lavender, and is somewhat analogous to that of oil of turpentine, with which it is said to be often adulterated. It is used by artists in the preparation of varnishes. The oil of spike contains about 30 per cent. of cincol and but small quantities of esters. Flückiger states (*A. J. P.*, 1885, p. 132) that from *Lavandula vera* 80,000 to 100,000 kilogrammes of oil are produced at Grasse every year, and from *Lavandula Spica* 20,000 to 25,000 kilogrammes. It is used chiefly as a perfume, though possessed of carminative and stimulant properties, and sometimes useful in cases of *nervous languor* and *headache*.

Dose, from one to five minims (0.06 to 0.3 Cc.).

Off. Prep.—*Linimentum Camphoræ Ammoniatum, Br.; Spiritus Lavandulæ, Br.; Tinctura Lavandulæ Composita, Br.*

OLEUM LAVANDULÆ FLORUM. U. S.

[OIL OF LAVENDER FLOWERS]

(ô'le-üm la-văn'dù-læ flô'rûm)

"A volatile oil distilled from the fresh flowering tops of *Lavandula officinalis* Chaix (Fam. *Labiata*). It should be kept in amber-colored, well-stoppered bottles, in a cool place, protected from light." *U. S.*

This superior kind of oil of lavender has been introduced into the Pharmacopeia because it was desirable that an inferior sort should not be used in the preparations into whose composition it enters. The properties of the oil are noticed in the preceding article. It is officially described as "a colorless or yellow liquid, having the fragrant odor of lavender flowers, and a pungent and slightly bitter taste. Specific gravity: 0.880 to 0.892 at 25° C. (77° F.). It is soluble in 3 parts of 70 percent. alcohol.

¹ *Antiseptic Catgut*.—Kocher of Berne, stated that a very fine antiseptic catgut may be made by first soaking the catgut for 24 hours in pure oil of juniper, and then immediately transferring it to alcohol of 95 per cent., in which it is preserved under tension, being wound (tightly stretched) upon a flat reel about 10 inches long. If the gut be placed for a day in glycerin before it is laid in the alcohol, it will become more pliable. The gut must be cut at the point of turning the edges of the reel, and for this reason the latter is chosen of such a size that the cut pieces of catgut shall be of the proper length. (*N. R.*, 1881, p. 270.) The catgut must be preserved in closed containers.

When the oil is shaken with water in a narrow graduated cylinder, its volume should not be diminished (absence of alcohol)." *U. S.*

Dose, one to six minims (0.06 to 0.4 Cc.).

Off. Prep.—Linimentum Saponis Mollis, *U. S.*; Spiritus Ammoniae Aromaticus, *U. S.*; Spiritus Lavandulae, *U. S.*; Tinctura Lavandulae Composita, *U. S.*; Unguentum Diachylon, *U. S.*

OLEUM LIMONIS. *U. S.*, Br.

OIL OF LEMON

(ō'le-ŭm lĭ-mō'nĭs)

"A volatile oil obtained by expression from fresh Lemon Peel, yielding, when assayed by the process given below, not less than 4 percent. of aldehyde, calculated as citral. It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "The oil obtained from fresh Lemon Peel." *Br.*

Oleum Limonum; Huile volatile de Citron, *Fr. Cod.*; Essence de Citron, *Fr.*; Oleum Citri, *P. G.*; Citronenöl, *G.*; Olio de limone, *It.*; Esencia de limon, *Sp.*

The exterior rind of the lemon abounds in a volatile oil, which, being contained in distinct cells, may be separated by simple expression. The rind is first grated from the fruit, and then submitted to pressure in a bag of fine cloth. The oil thus obtained is allowed to stand till it becomes clear, when it is decanted, and kept in stoppered bottles. By a similar process, the oil called by the French *huile de cédrat* is procured from the citron. (See *Oleum Bergamotte*, PART II, and *Limonis Succus*.) These oils may also be obtained by distillation, but thus procured, though clearer, and, in consequence of the absence of mucilage, less liable to change on keeping, they have less of the peculiar flavor of the fruit, and the mode by expression is generally preferred. A third method of separating the oil, used in Calabria and Sicily, is to put the grated rind into hot water and skim off the oil as it rises to the surface. (*A. J. P.*, 1868, p. 27.) The method employed to obtain the finest oil is, however, that known as the *écuelle* process. The *écuelle* is an instrument usually made of tinned copper, bowl-shaped, and armed with concentric rows of short spikes. Attached to the bottom of the bowl is a hollow handle, closed at the bottom. This acts as a reservoir for the oil as the fruit is rubbed by the workmen over the sharp teeth. The oils are brought from Italy, Portugal, or Southern France.

The oils of lemons and oranges, as well as those of the other Aurantiaceæ, will keep indefinitely upon admixture with a small proportion of alcohol (one ounce to a pound of the oil).¹ When wanted for use, a quantity of water

equal to that of alcohol, added to the mixture, will unite with the alcohol, and subside, leaving the oil free of the alcohol for all practical purposes. (Carl Fröh, *A. J. P.*, 1871, 201.) The great extent of the production and export of Sicilian and Calabrian essential oils (lemon, orange, bergamot, etc.) may be seen from the Italian official statistics, according to which the number of trees producing in 1896 was 17,084, 569, yielding 3,337,000,000 fruits. Of these 1,897,000,000 were exported, leaving 1,439,555, 000 fruits for home consumption inclusive of those used in the manufacture of essences. (*Schim. Rep.*, Oct. 1897, 23.)

Properties.—Oil of lemon is "a pale yellow, limpid liquid, having the fragrant odor of lemon, and an aromatic, somewhat bitter taste." *U. S.* As commonly procured, it is yellow, but by distillation it is rendered colorless, and, if three-fifths only are distilled, its sp. gr. is reduced to 0.847 at 71° F. "Specific gravity: 0.851 to 0.855 at 25° C. (77° F.). It is dextrogyrate; its optical rotation should not be less than +60° in a 100 Mm. tube, at a temperature of 25° C. (77° F.). The angle of rotation of the first 10 percent. of oil obtained by fractional distillation should not differ more than 2° from that of the original Oil." *U. S.* "Specific gravity 0.857 to 0.860. It should rotate the plane of a ray of polarized light not less than 59° to the right in a tube 100 millimetres long; and if 100 volumes be fractionally distilled, the 10 volumes first collected should not produce a rotation differing by more than 2° from that produced by the original Oil." *Br.*

Assay for Citral. *U. S.* (8th Rev.).—"Introduce into a counterpoised 150 Cc. flask, by means of a pipette, about 15 Cc. of Oil of Lemon, and note the exact weight; add 5 Cc. of distilled water and a few drops of phenolphthalein T.S., and then neutralize the liquid exactly by the cautious addition of tenth-normal sodium hydroxide V.S. Add 25 Cc. of a neutral solution of sodium sulphite (1 in 5), and immerse the flask in a water-bath containing boiling water. From a burette add, as needed, just sufficient half-normal hydrochloric acid V.S. to maintain the neutrality of the mixture, keeping the flask continuously heated and frequently agitated, and adding a drop or two of phenolphthalein T.S. When a permanent condition of neutrality is reached, note the number of cubic centimeters of the half-normal hydrochloric acid V.S. consumed. Carry out a blank test, identical with the foregoing, except that the Oil of Lemon is omitted, and note the amount of half-normal hydrochloric acid V.S. consumed. Subtract the number of cubic centimeters re-

quency, to make one thousand cubic centimeters [or 33 fluidounces, 390 minims]. Dissolve the Oil of Lemon in nine hundred cubic centimeters [or 30 fluidounces, 208 minims] of Deodorized Alcohol, add the Lemon Peel, and macerate for twenty-four hours. Then filter through paper, and add, through the filter, enough Deodorized Alcohol to make the Spirit measure one thousand cubic centimeters [or 33 fluidounces, 390 minims]." *U. S.*, 1890.

This spirit is used chiefly for flavoring mixtures.

¹ *Spiritus Limonis*. *U. S.* 1890. *Spirit of Lemon*. [*Essence of Lemon*.]—"Oil of Lemon, fifty cubic centimeters [or 1 fluidounce, 381 minims]; Lemon Peel, freshly grated, fifty grammes [or 1 ounce av., 334 grains]; Deodorized Alcohol, a sufficient quan-

quired in the blank test from the number required in the original test; each Cc. of this difference corresponds to 0.03802 Gm. of citral. To find the percentage, multiply the above difference by 0.03802, and this product by 100, and divide by the weight of the Oil of Lemon taken." *U. S.*

Oil of lemon contains a small amount of *pinene*, with dextrogyrate *limonene*, about 7 to 8 per cent. of *citral*, $C_{10}H_{16}O$, an aldehyde yielding geraniol upon reduction, and a small amount of *citronellal*, $C_{10}H_{16}O$, also an aldehyde. Of these the citral is the constituent to which the oil chiefly owes its aroma and value. Umney and Swinton (*P. J.*, 1898, 196) state that citral, citronellal, and an ester of geraniol are all necessary to form the true odor of oil of lemon. Citral boils under normal atmospheric pressure at from 228° to 229° C. without decomposition if pure, and, like aldehydes, forms stable compounds with alkaline bisulphites. Schimmel & Co. now prepare the citral in a pure state, and recommend its use for enriching the ordinary oil of lemon.

Oil of lemon is often adulterated by the fixed oils and by alcohol, but in this country one of the most frequent sophistications is with purified oil of turpentine, which is difficult of detection from its similar composition and specific gravity. One of the tests for the presence of this oil is the terebinthinate odor produced when the adulterated oil is evaporated from heated paper; the official quantitative test defining the percentage of citral will be of service in detecting these adulterations. The most dangerous adulteration of oil of lemon is the use of *citrene*, the terpene left after the extraction of citral from oil of lemon which has been used in making terpeneless oil. Oil of lemon procured by expression is apt to let fall a deposit and to undergo chemical change. J. S. Cobb has found no method so effectual to obviate this result, and at the same time to retain unimpaired the flavor of the oil, as to shake it with a little boiling water and allow the mixture to stand. A mucilaginous matter separates, and floats on the surface of the water, from which the purified oil may be decanted. (*Ann. Pharm.*, ii. 86.)

Uses.—Oil of lemon has the stimulant properties of the aromatics, but is used chiefly to impart flavor to other medicines.

Dose, three to six minims (0.2 to 0.4 Cc.).

Off. Prep.—Linimentum Potassii Iodidi cum Sapone, *Br.*; Spiritus Ammoniz Aromaticus, *U. S.*, *Br.*; Spiritus Aurantii Compositus, *U. S.*; Tinctura Guaiaci Ammoniata, *Br.*; Tinctura Valerianæ Ammoniata, *Br.*

OLEUM LINI. *U. S.*, *Br.*

LINSEED OIL [Oil of Flaxseed]

(δ'le-ūm lī'nī)

"A fixed oil expressed from Linseed. It should be kept in well-stoppered containers.

Linseed Oil which has been 'boiled' should not be used nor dispensed." *U. S.* "The oil expressed from Linseed at ordinary temperatures." *Br.*

Hulle de Semence de Lin, *Fr.*; Oleum Lini, *P. G.*; Leinöl, Leinsamenöl, *G.*; Ollo di lino, *It.*; Aceite de linaza, *Sp.*

This oil is obtained by expression from the seeds of *Linum usitatissimum*, or common flax, which, according to Berjot, contain 34 per cent. (*J. P. C.*, Avril, 1863, p. 277.) In its preparation on a large scale, the seeds are usually roasted before being pressed, in order to destroy the gummy matter contained in their coating. The oil is thus obtained more free from mucilage, but more highly colored and acrid, than when procured by cold expression. For medicinal use, therefore, it should be prepared without heat, and, as it is apt to become rancid quickly on exposure, it should be used as soon after expression as possible. It may, however, be rendered sweet again by agitation with warm water, rest, and decantation. It is said to be obtained purer and in larger proportion by treating the crushed seeds with carbon disulphide, than by expression. (*A. J. P.*, xxvi. 265.)

Oil of flaxseed is "a yellowish,¹ oily liquid, having a peculiar odor and a bland taste. When exposed to the air, it gradually thickens, darkens in color, and acquires a strong odor and taste; if spread in a thin layer on a glass plate and allowed to stand in a warm place, it is gradually converted into a hard, transparent resin (absence of *non-drying oils*). Specific gravity: 0.925 to 0.935 at 25° C. (77° F.). It does not congeal at temperatures above -20° C. (-4° F.). It is soluble in about 10 parts of absolute alcohol, and in all proportions in ether, chloroform, petroleum benzine, carbon disulphide, and oil of turpentine. It should not more than slightly redden blue litmus paper previously moistened with alcohol (limit of *free acid*). The Oil should be completely saponifiable with alcoholic potassium hydroxide T.S., and the resulting soap should be completely soluble in water without leaving an oily residue (absence of *mineral oils* and *rosin oil*). If 2 Cc. of the Oil be warmed and shaken in a test-tube with an equal volume of glacial acetic acid, and if to this mixture, after cooling, 1 drop of sulphuric acid be added, a greenish color should be produced (a violet color under these circumstances indicates the presence of *rosin* or *rosin oils*). Linseed Oil saponified by alcoholic potassium hydroxide T.S. should show a saponi-

¹ The following method of bleaching flaxseed, rapeseed, and poppyseed oils was recommended by C. Fischer. He mixed 100 kilogrammes of the oil with 2 kilogrammes of a mixture of equal weights of sulphuric acid and alcohol of 96 per cent. The sulphuric acid mixes uniformly with the oil; the mixture soon assumes a green turbidness, which afterwards becomes black, and in 24 or 48 hours the liquid becomes clear by the deposition of a black sediment. It is necessary to wash the oil with hot water, to separate the little remaining acid. Linseed oil in bulk shows merely a yellowish tint; the other oils mentioned become quite colorless. (*A. J. P.*, 1873, p. 110.)

fication value of from 187 to 195 (see PART III, Test No. 99). If 0.15 Gm. of Linseed Oil be dissolved in 10 Cc. of chloroform in a 250 Cc. flask, and 25 Cc. of a mixture of equal volumes of alcoholic iodine T.S. and alcoholic mercuric chloride T.S. added, and if, after standing for sixteen hours protected from the light, 20 Cc. of potassium iodide T.S. be introduced and the mixture diluted with 50 Cc. of water, on titrating the excess of iodine with tenth-normal sodium thiosulphate V.S., an iodine value of not less than 170 should be obtained (see PART III, Test No. 51)." *U. S.* "Viscid, yellow, with a faint but distinct odor, and bland taste. Specific gravity 0.930 to 0.940. It is soluble in 10 parts of alcohol (90 per cent.), and in Oil of Turpentine. It gradually thickens by exposure to the air, forming, when spread in a thin layer on glass, a hard transparent varnish. It does not congeal above -4° F. (-20° C.)" *Br.* It has the property of drying or becoming solid on exposure to the air, acquiring during the process a strong odor and taste, and increasing as much as 12 per cent. of its weight, owing to the formation of *linoxyn* by atmospheric oxidation. The drying property resides in a constituent which, to distinguish it from the olein of the non-drying oils, is named *linolein*, and is the glyceride of *linoleic acid*. Linseed oil contains about 10 to 15 per cent. of glycerides of solid fatty acids and 85 to 90 per cent. of liquid glycerides. Hazura (*J. Soc. Chem. Ind.*, 1888, 506) states that the liquid fatty acids consist of about 5 per cent. of *oleic acid*, $C_{18}H_{34}O_2$, 15 per cent. of *linoleic acid*, $C_{18}H_{32}O_2$, 65 per cent. of *isolinolenic acid*, $C_{18}H_{30}O_2$, and 15 per cent. of *linolenic acid*, $C_{18}H_{30}O_2$. Boiled with litharge, red lead, manganese dioxide, and other so-called "driers," it absorbs oxygen still more rapidly, and gains 14 per cent. in weight. Its acrimony is owing to the presence of a small proportion of an acrid oleoresin. From its drying property, it is useful in painting and in making printers' ink. The chief adulteration of linseed oil is with mineral oils and rosin oil. For their detection see official tests already given.

It is said that crude cod liver oil has been used for the adulteration of the oil of flaxseed, especially where the latter is intended for preparing printers' ink. Aug. Morell detects the adulteration by the following method. Take 10 parts by weight of the suspected oil, mix it in a small cylindrical glass tube with 3 parts of crude nitric acid, agitate the mixture well, and allow it to rest. If cod liver oil be present, the oily layer at top will assume a dark-brown to blackish-brown color, while the acid at bottom will vary from bright orange to orange or dark yellow. So little as 3 per cent. of cod liver oil may thus be detected. If the flaxseed oil be pure, it will become, during the agitation, first sea green, and afterwards dirty greenish yellow, the acid being bright yellow.

Uses.—The oil is laxative in the dose of a fluidounce (30 Cc.), but, on account of its dis-

agreeable taste, is seldom given internally. It has, however, been highly recommended as a cure for *piles*, in the dose of two fluidounces (60 Cc.) of the fresh oil morning and evening. It is sometimes added to purgative enemata.¹

Dose, one to two fluidounces (30 to 60 Cc.).

OLEUM MENTHÆ PIPERITÆ. U. S.,

Br.

OIL OF PEPPERMINT

(δ'λ'ε-ūm mēn'thæ pīp-ē-rītæ)

"A volatile oil distilled from the fresh or partly dried leaves and flowering tops of Peppermint, rectified by steam distillation, and yielding, when assayed by the process given below, not less than 8 percent, of ester, calculated as menthyl acetate, and not less than 50 percent. of total menthol (free and as ester). It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "The oil distilled from fresh flowering peppermint, *Mentha piperita*, *Sm.*" *Br.*

Hulle volatile de Menthe poivrée, *Fr. Cod.*; Essence de Menthe poivrée, *Fr.*; Oleum Menthæ piperitæ, *P. G.*; Pfefferminzöl, *G.*; Essenzia di menta, *It.*; Esencia de menta piperita, *Sp.*

Peppermint varies exceedingly in the quantity of oil which it affords. Four pounds of the fresh herb yield, according to Baumé, from a drachm and a half to three drachms of the oil. Zeller gives as the product of the fresh herb, from 0.37 to 0.68 per cent., of the dried 1.14 per cent. The yield is generally less than 1 per cent. This oil is largely distilled in the States of Michigan, Indiana, and New York. For a valuable account of its method of production in Michigan, by A. M. Todd, see *A. J. P.*, 1888, 328. The oil is also largely produced in Japan. (See illustrated paper, *C. D.*, 1896, 601.) Gildemeister and Hoffmann (*Ätherische Oele*, p. 836) estimate the world's production of peppermint oil at 175,000 kilos, of which the United States furnishes 90,000 kilos, and Japan 70,000 kilos. It is offi-

¹ *Oiled Paper.*—A substitute for waxed cloth for the dressing of wounds and ulcers, prepared in the following manner by Gauthier of Geneva, with flaxseed oil, has been highly recommended. To facilitate its drying, 3 liters (about 6.4 pints) of the oil are boiled for an hour or two with 30 grains of lead acetate, 30 grains of litharge, 15 grains of yellow wax, and 15 grains of turpentine. Thus prepared, the oil is spread upon silk-paper by means of a brush on both surfaces. On the top of the first sheet another is then placed so as to overlap it at one corner. The lower surface of the second sheet thus becomes impregnated with the oil, which now requires to be applied only to the upper. Any desired number of sheets may be thus successively superimposed. They are then separated, and suspended in a drying apartment, attached to a cord by means of hooks or pins. When dry, they should be sprinkled with powdered talc, to prevent adhesion, and packed away. (*J. P. C.*, *Mal*, 1860, p. 363.)

cially described as "a colorless liquid, having the characteristic, strong odor of peppermint, and a strongly aromatic pungent taste, followed by a sensation of cold when air is drawn into the mouth. Specific gravity: 0.894 to 0.914 at 25° C. (77° F.). It forms a clear solution, neutral to litmus paper, with an equal volume of alcohol; also soluble in 4 volumes of 70 percent. alcohol, the solution showing not more than a slight opalescence. It is lævogyrate, the angle of rotation varying from -25° to -33° in a 100 Mm. tube, at a temperature of 25° C. (77° F.). If from 25 Cc. of Oil about 1 Cc. be distilled and the distillate poured on an aqueous solution of mercuric chloride, a white film should not form at the zone of contact after a short time (absence of *dimethyl sulphide* found in non-rectified oils)." *U. S.* "Specific gravity 0.900 to 0.920. It should dissolve in four times its volume of alcohol (70 per cent.). If a portion of the Oil be cooled to 17° F. (-8.3° C.) and a few crystals of Menthol be added, a considerable separation of menthol should take place." *Br.*

Assay.—"Introduce into a tared flask 10 Cc. of Oil of Peppermint, and note the exact weight; add 25 Cc. of half-normal alcoholic potassium hydroxide V.S., connect with a reflux condenser, and boil the mixture during one hour. After cooling, titrate the residual alkali with half-normal sulphuric acid V.S., using phenolphthalein T.S. as indicator. Subtract the number of cubic centimeters of half-normal sulphuric acid V.S. required from the 25 Cc. of half-normal alcoholic potassium hydroxide V.S. taken, multiply the difference by 9.834, and divide the product by the weight of the Oil of Peppermint taken to find the percentage of menthyl acetate. Wash the residual oil repeatedly with water, transfer it to a flask provided with a ground-glass tube-condenser (acetylation flask), add 10 Cc. of acetic acid anhydride and about 1 Gm. of anhydrous sodium acetate, and boil gently during one hour. Allow it to cool, wash the acetylated oil with distilled water, and afterwards with sodium hydroxide T.S., until the mixture is slightly alkaline to phenolphthalein T.S., and then dry it with the aid of fused calcium chloride, and filter.

Transfer to a tared 100 Cc. flask 5 Cc. of the dry acetylated oil, note the exact weight, add 50 Cc. of half-normal alcoholic potassium hydroxide V.S., connect with a reflux condenser, and boil the mixture during one hour. After cooling, titrate the residual alkali with half-normal sulphuric acid V.S., using phenolphthalein T.S. as indicator. Subtract the number of cubic centimeters of half-normal sulphuric acid V.S. required from the 50 Cc. of half-normal alcoholic potassium hydroxide V.S. taken, multiply the difference by 7.749, and divide the product by the weight of the dry acetylated oil taken, less the above difference multiplied by 0.021; the quotient will represent the percentage of menthol in the Oil of Peppermint.

NOTE.—The difference referred to above represents the number of cubic centimeters of half-normal alcoholic potassium hydroxide V.S. consumed by the acetylated oil." *U. S.*

Upon cooling or long standing it deposits a stearopten. Berzelius stated that at -8° F. the oil deposits small capillary crystals. These, which are called *peppermint camphor* or *menthol*, $C_{10}H_{18}OH$, melt at 42° C. (107.6° F.), boil at 212° C. (413.6° F.), volatilize unchanged, and, when distilled with phosphoric anhydride, yield a peculiar aromatic product, denominated *menthene*, $C_{10}H_{18}$. A complete summary of the composition of American peppermint oil, on the authority of Power and Kleber, given in *Schimmel & Co's Report* for April, 1897, shows the following constituents: acetaldehyde, isovaleraldehyde, dimethyl sulphide, amyl alcohol, isovaleric acid, pinene, phellandrene, cineol, limonene, *menthone*, $C_{10}H_{18}O$, menthol, the acetate and isovalerate of menthyl, *α -lactone*, $C_{10}H_{18}O_2$, and cadinene. Menthol, its oxidation product menthone, and the acetic and isovaleric esters of menthyl have been identified as present in English and French peppermint oils, which probably also contain most of the other constituents mentioned above. Menthol and its esters are regarded as the main constituents of oil of peppermint and an official assay for determining the percentage of menthol will be found above. The polariscope has been shown to be an uncertain guide in determining the quality of oil of peppermint. (A. B. Stevens, *Proc. A. Ph. A.*, 1888, p. 97.)

Flückiger discovered that from 50 to 70 drops of peppermint oil, shaken with one drop of nitric acid, sp. gr. 1.2, turn faintly yellowish brown, and after an hour or two a most beautiful blue violet or greenish blue by transmitted light, or copper color by reflected light. Either a greater amount of acid or heating hastens the reaction. The color is very persistent. The presence of 5 per cent. of turpentine does not interfere with the reaction. (*P. J.*, Feb. 1871.) This oil is frequently adulterated with alcohol, and occasionally, there is reason to believe, with oil of turpentine, and even oil of copaiba. Oil of turpentine is detected by its odor, by its difficult solubility in cold alcohol, and by its imparting the property of exploding with iodine. According to H. Martin, the copaiba is to be detected by the mass acquiring the consistence of butter when heated to boiling with concentrated sulphuric acid. (*N. R. Pharm.*, xvii. 635.) It is stated by Hotchkiss that in much of the land under culture with peppermint in this country other oil producing plants are carelessly allowed to grow, which, being gathered and distilled with the peppermint, contaminate the product. (*A. J. P.*, xxvii. 222.) The plant which has proved most troublesome to the mint growers is of the *Erigeron* family, and Vigier and Cloez have given the following tests to detect oil of erigeron, which will indicate the presence of eight or ten per cent. of it. Concentrated po-

tassium hydroxide does not saponify erigeron oil, but colors it orange-red in the cold; on heating, the color deepens until part of the oil separates as a reddish-purple viscid mass. This reaction does not show itself with oil freshly distilled at 170° C. Pure mint oils do not give this reaction; in the cold, potassium hydroxide converts them into a white emulsion; on heating, the mixture acquires a faint, clear, yellow tinge; but, if a few drops of erigeron oil are introduced, the orange-red color appears quickly on shaking, and develops instantly if the tube is warmed. Mint oil is completely soluble, erigeron oil is completely insoluble, in its own volume of 85 per cent. alcohol at 15° C. (59° F.). If a suspected sample be agitated with an equal volume of 85 per cent. alcohol, a milky fluid will be produced if erigeron oil be present, and the insoluble essence will separate in the course of twenty-four hours. The oils of *Eucalyptus Globulus* and turpentine behave in much the same way, and the points which would distinguish the three substances have not yet been determined. But a specimen of mint oil which rotates the polarized ray feebly to the left, makes a turbid mixture with its own volume of 85 per cent. alcohol, and takes an orange-red tint with potassium hydroxide, may be safely rejected. (*N. R.*, Jan. 1882; from *L'Union Pharmaceutique*.) Since menthol has been prepared largely from American peppermint oil, much of the latter has been put upon the market deprived of its menthol. To detect this fraud, Fritzsche Brothers recommend that a test tube partially filled with the oil and corked should be placed in a freezing mixture of ice and salt for ten or fifteen minutes. At the end of that time, if the oil has not been tampered with, it will have become cloudy, thick, or of a jelly-like consistence. If then four or five small crystals of menthol be added, and the tube be replaced in the freezing mixture, the oil will in a very short time form a solid mass of crystals. For another method of testing dementholized oil, see a paper by E. C. Federer, *Ph. Era*, 1887, 36; also 1887, 97.

Power and Kleber first proposed (*Ph. Rund.*, 1894, 157) to estimate the menthol in oil of peppermint by acetylizing a sample and saponifying an exactly weighed portion of the acetylated oil after washing, drying, and filtering the same. Kebler (*A. J. P.*, 1897, 192) proposed to take instead a weighed quantity of the oil, acetylate it, and then saponify the product after washing and neutralizing it. In *Schimmel & Co's Report* for October, 1897, Kleber criticises Kebler's modification, and claims greater accuracy for the original method. Of course this determination gives the total menthol; a determination of the combined menthol is had by titrating with alcoholic alkali. Quetting & Co. furnish the following test for detecting the presence of oil of pennyroyal: "Take one drachm hydrated chloral and half a drachm C. P. sulphuric acid; mix them in a glass mortar, add a few drops of alcohol, and

stir until it becomes clear. Then use this mixture in equal proportions with the suspected oil in a small porcelain dish, and mix thoroughly together. The result will be a fine cherry-red color, if the oil be pure; otherwise, if mixed with pennyroyal, it will turn a dark olive-green, more or less according to the extent of adulteration." (*N. R.*, Jan. 1882.) Such impurities may usually be detected by the altered odor of the oil. Flückiger has found that hydrated chloral develops only a slightly brown or yellow color, while anhydrous chloral changed some specimens of the oil to brown and others to green. He also found great differences in the action of sodium bisulphite, the coloring varying from green to rose-red or violet. (*A. J. P.*, 1874, 274.) According to Trebault, when picric acid is added in the cold no change occurs for half an hour, when a green color suddenly develops. The green produced has a showy red fluorescence. Sulphuric acid develops a rose color, passing through reddish yellow to reddish brown; hydrochloric acid a rose color, rather slowly; nitric acid a rose color, then red, becoming greenish. (For further particulars, see *P. J.*, June, 1874, p. 977.) C. Roucher states that when to acetic acid is added one-twentieth of its weight of oil of peppermint, with agitation, in an hour the liquid becomes deep blue by transmitted and a cinnabar-red by reflected light. The coloration is not stable, but passes through green to yellow in the light. To detect alcohol, Hager puts ten to fifteen drops of the oil in a test tube with a piece of tannic acid the size of a pea; if even one-half per cent. of alcohol be present, after two or three hours the tannin will be softened or dissolved. (*A. J. P.*, xlv. 104.)

Chinese Oil of Peppermint has not found its way to any extent into commerce, yet it has at times attracted much attention. According to John Mackey, some of it has reached London in cylindrical tin canisters, and it is to be obtained in San Francisco. Some specimens resemble the ordinary oil, but become solid in cold weather; others remain liquid and show no tendency to deposit a camphor, while others are solid crystalline masses at all temperatures. It seems probable that the original Chinese oil contains a great excess of menthol, and constitutes the variety first spoken of, and that the solid and liquid oils are prepared by separating it into its two constituents. The solid oil Flückiger states not to differ from American menthol. (See *P. J.*, v. 366, 825.)

Oil of peppermint is stimulating and carminative, and is much used in *flatulence*, *nausea*, *spasmodic pains* of the stomach and bowels, and as a corrigent or adjuvant of other medicines. In *neuralgia* it is one of the best external remedies at our command, and is said to have been used in China from time immemorial. A cloth wet with it is to be laid upon the affected part, evaporation being restrained by oiled muslin or other covering. In *rheumatism* also it is a very useful anodyne counter-

irritant. It is most conveniently given rubbed with sugar and then dissolved in water. The oil is frequently employed dissolved in alcohol, in the form of *essence of peppermint*; the official spirit of peppermint should alone be used. (See *Spiritus Menthæ Piperitæ*.)

Dose, two to ten minims (0.12 to 0.6 Cc.).

OLEUM MENTHÆ VIRIDIS. U. S., Br.

OIL OF SPEARMINT

(ō'le-ūm mēn'thæ vīr'ī-dis)

"A volatile oil distilled from the fresh or partly dried leaves and flowering tops of Spearmint, rectified by steam distillation. It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "The oil distilled from fresh flowering spearmint, *Mentha viridis*, *Linn.*" *Br.*

Hulle volatile (Essence) de Menthe verte, *Fr.*; Römischminzöl, Krauseminzöl, *G.*

According to Lewis, ten pounds of spearmint yield an ounce of oil; by others the product is stated not to exceed one part from five hundred. The oil is largely distilled in this country, the whole plant being used. It is pale yellow or greenish when recently prepared, but becomes red with age, and ultimately almost of a mahogany color. Its flavor is analogous to that of oil of peppermint, but less pungent. It is officially described as "a colorless, yellow, or greenish-yellow liquid, having the characteristic, strong odor of spearmint, and a hot aromatic taste. Specific gravity: 0.914 to 0.934 at 25° C. (77° F.). With an equal volume of 80 percent. alcohol it forms a clear solution, which upon further dilution becomes turbid. It is lævogyrate, the angle of rotation varying from -35° to -48° in a 100 Mm. tube, at a temperature of 25° C. (77° F.)." *U. S.* "Specific gravity 0.920 to 0.940. The Oil forms a clear solution with its own volume of a mixture of equal parts of *absolute alcohol* and *alcohol* (90 per cent.)." *Br.* Gladstone (*Jahresb.*, 1863, 548) states that it contains a terpene, $C_{10}H_{16}$, and a compound, $C_{10}H_{14}O$, identical with carvone, which boils at 225° C. (437° F.) and has the sp. gr. 0.9515. Henry Trimble (*A. J. P.*, 1885, 484) confirmed these results, working with authentic samples of American oil. Baeyer found lævogyrate carvone in both German and American oils to the amount of from 35 to 56 per cent. (*A. Pharm.*, 212, 283.) Schimmel & Co., in an investigation of Russian oil, found from 5 to 10 per cent. of carvone only, but 50 to 60 per cent. of linalool, together with some cineol and

lævogyrate limonene. (*Schim. Rep.*, April, 1898.) It is used for the same purposes as the oil of peppermint.

Dose, two to six minims (0.12 to 0.4 Cc.). An *essence of spearmint*, prepared by dissolving the oil in alcohol, is sold in commerce, but the official spirit should be exclusively used. (See *Spiritus Menthæ Viridis*.)

OLEUM MORRHUÆ. U. S., Br.

COD LIVER OIL [Oleum Jecoris Aselli]

(ō'le-ūm mōr'rhu-æ)

"A fixed oil obtained from the fresh livers of *Gadus morrhua* Linné, and of other species of *Gadus*. It should be kept in a cool place, in well-stoppered bottles, which have been thoroughly dried before filling." *U. S.* "The oil extracted from the fresh liver of the cod, *Gadus Morrhua*, *Linn.*, by the application of a temperature not exceeding 180° F. (82.2° C.); and from which solid fat has been separated by filtration at about 23° F. (-5° C.)." *Br.*

Oleum Hepatis Morrhue; Cod Oil; Huile de Fole de Morue, *Fr. Cod.*; Huile de Morue, *Fr.*; Oleum Jecoris Aselli, *P. G.*; Leberthran, Stockfischleberthran, Dorschleberthran, Kabilanleberthran, *G.*; Ollo di fegato di merluzzo, *It.*; Aceite de higado de bacalao, *Sp.*

Gadus morrhua, *Linn.*, *Syst. Nat.*, ed. Gmelin, i. p. 1162; Cuvier, *Règne Animal*, ii. 212, Bloch, *Ichthyologie*, pl. lxiv.—*Morrhua vulgaris*, Storer, *Synopsis of Fishes of N. Am.*, p. 216.—The common cod is between two and three feet long, with brown or yellowish spots on the back. The body is moderately elongated and somewhat compressed, and covered with soft rather small scales, of which the head is destitute. Of the fins, which are soft, there are three on the back, two anal, and a distinct caudal, and the fin under the throat is narrow and pointed. The jaws are furnished with pointed irregular teeth, in several ranks. The gills are large, with seven rays. This species of cod inhabits the Northern Atlantic, and is especially abundant on the Banks of Newfoundland, where it finds food adapted to its wants.

Besides the common cod, several other species of *Gadus*, frequenting the seas of Northern Europe and America, contribute to furnish the cod liver oil of commerce. Among these De Jongh mentions *Gadus callarias*, or *dorsch* (*Morrhua americana* of Storer), *G. molva*, or *ling*, *G. carbonarius*, or *coal fish*, and *G. pollachius*, or *pollack*, as affording the oil on the coast of Norway, where from 17,000,000 to 35,000,000 of codfish are annually taken,¹

¹ For an account of the mode of fishing for cod and of preparing the oil practised in Norway and Denmark, see *P. J.*, Jan. 1868, p. 312, also April, 1877, p. 810; *N. R.*, March, 1878; *J. P. C.*, 4e sér., iv. 324, 1866; *Ph. Ztg.*, 1900, 261; *Ph. Era*, 1904, 111; *O. D.*, 1904, 21.

while on our own coast, in addition to the pollack above mentioned, it is obtained also from the *hake* (*G. merluccius*) and the *haddock* (*G. æglefinus*). It is largely produced on our coast north of Boston.¹

Preparation.—Fishermen have long been in the habit of collecting this oil, which is largely consumed in the arts, particularly in the preparation of leather. Upon the coasts of Newfoundland, Nova Scotia, and New England, the boats which fish near the shore, being small, soon obtain a load, and, running in to land, deliver their cargoes to persons whose business it is to cleanse and salt the fish. The oil is prepared either in the huts of the fishermen or more largely at establishments to which the livers are conveyed in quantities. These are put into a boiler with water, and heated until they are broken up into a pulaceous mass, which is thrown upon a strainer covering the top of a cask or tub. The liquid portion passes, and upon standing separates into two parts, the oil rising to the surface of the water. The oil is then drawn off, and, having been again strained, is prepared for the market. Another and improved method, which has come into use since the extensive employment of the oil as a medicine, is to heat the livers in a wooden butt by means of low pressure steam. The pulaceous mass resulting is drained as before mentioned,—the livers themselves containing, besides oil, a considerable portion of aqueous fluid, which passes off with it in the form of emulsion and separates on standing. In the case of the finest American varieties, the oil, which is made only in the winter months, is drawn off by taps from the bottom of the cooking butt, and then put into a cooling house to freeze. The solid frozen mass is put into canvas bags, and submitted, while at a low temperature, to severe pressure, whereby the pure liquid oil is forced out, leaving a whitish, tallow-like mass, composed of stearin and liver débris. This residue is sold to the soap makers, and the oil bottled without further process. The oil thus variously procured is called *shore oil*, and is the purest kind. The manufacture of refined oil by improved processes is developing rapidly in Newfoundland. (See *West. Drug.*, 1897, 13.)

The crews of the larger boats, which fish upon banks far from land, cleanse the fish on board, and, throwing the offal into the sea, put the livers into barrels or other receptacles, where they undergo a gradual decomposition,

the oil rising to the surface as it escapes from the disintegrating tissue. The oil which first rises, before putrefaction has very decidedly commenced, approaches in purity to the shore oil, but is somewhat darker and less sweet. This is sometimes drawn off, constituting the *straits oil* of the fishermen. The remaining mass, or the whole, if the portion which first rises is not separated, continues exposed for a variable length of time to the heat of the sun, undergoing putrefaction, until the boat, having completed her cargo, returns to port. The contents of the casks are then put into boilers, heated with water, and treated as already described. Before being finally put into barrels, the oil is heated to expel all its water. Thus prepared, it is denominated *banks oil*, and is of the darkest color, and most offensive to the taste and smell. Much of the oil prepared by the fishermen is collected by the wholesale dealers, who keep it in very large reservoirs of masonry in their cellars, where it becomes clarified by repose, and is pumped into barrels as wanted for sale. By the further exposure, however, which it thus undergoes, it acquires a still more offensive odor, while that which has been originally introduced into barrels, and thus kept secluded from the air, is better preserved. For further details, see *A. J. P.*, xxiii. 97, xxvi. 1. Large quantities of Norwegian cod liver oil are sold in the United States; the method of extraction depending on the action of steam does not differ greatly from that used in America. Another oil is made by the cold process and B. Rautitz, *Ph. Ztg.*, 1900, 261, furnishes the following account: The fresh livers, separated from the gall-bladder, are placed in a wooden tub, 5 ft. in height by 7 ft. in diameter, until the tub is nearly full, which is then left exposed to the action of the sun, shining day and night in these high latitudes. After about three weeks the extraction is completed, and, owing to the favorable atmospheric conditions and the evident absence of germs in this far polar region, not the slightest evidence of decomposition manifests itself during this process. The oil runs off pure and simply has the odor characteristic of cod liver oil, and while the “steam cod liver oil” requires refining, that obtained by the “cold process” described is ready for the market as run off from the tubs. This explains why in more southerly latitudes it is impossible to prepare a satisfactory cod liver oil; the cold process is not available, while the steam process does not yield a desirable oil.

The oil is sometimes procured by expression. Donovan recommends the following plan, which affords a very fine oil. The livers, perfectly sound and fresh, are to be placed in a clean iron pot over a slow fire, and stirred until they assume the condition of a pulp, care being taken that the mass be not heated beyond 192° F. When this temperature is attained, the pot is to be removed from the fire, and its contents

¹ *Dugong Oil.*—An oil has been brought into notice, as a substitute for cod liver oil, obtained from two species of *Halocore*, *H. australis*, Owen, and *H. dugong*, Illig, cetaceous animals inhabiting the rivers and bays of Northern and Eastern Australia and many of the East India islands. The flesh of these animals is said to be delicate and palatable and valued for food. The oil is obtained by boiling the superfluous fat. It is bland and sweet, and free from disagreeable taste and odor, so that it may be taken more freely than cod liver oil, which it is thought to equal in virtues. It was introduced into use by W. Hobbs, a surgeon of Brisbane. (*Chem. News*, Jan. 28, 1860, p. 87, and *A. J. P.*, 1868, p. 335, 1860, p. 230.)

introduced into a canvas bag, through which water and oil will flow into a vessel beneath. After twenty-four hours, the oil is to be decanted and filtered through paper. In this state it is pale yellow, with little odor, and a bland not disagreeable taste.

Properties.—Three varieties of cod liver oil are known in the market, the *white* or *pale yellow*, the *brownish yellow*, and the *dark brown*, corresponding to the three commercial varieties already mentioned. These varieties differ in no essential character, but simply from the mode of preparation, the pale being prepared from fresh sweet livers, the dark brown from livers in a state of putrefaction, and the brownish yellow from those in an intermediate state, and the three varieties run together by insensible shades. The color of the pale is from the slightest tint of transparent yellow to a fine golden yellow, that of the light brown very similar to the color of Malaga wine, and that of dark brown what its name implies, with opacity in mass, but transparency in thin layers. They are of the usual consistence of lamp oil, and have a characteristic odor and taste, by which they may be distinguished from other oils. This odor and taste are familiar to most persons, being very similar to those of shoe leather,—at least as prepared in this country, where the curriers make great use of cod liver oil. We regard these sensible properties as the most certain tests of the genuineness of the oil. They are much less distinguishable in the pale than in the dark brown varieties, but we have met with no specimen which did not possess them in some degree. In the purest they are scarcely repulsive, in the dark brown they are very much so. When a decided odor of ordinary fish oil is perceived, the genuineness may always be suspected. It is quite distinct from that peculiar to the cod liver oil. The taste of all, except the very finest varieties, is more or less acrid, and in the most impure is bitterish, and somewhat empyreumatic. The pale yellow oil is now exclusively used for medicinal purposes. The sp. gr. at 72° F., as ascertained by Procter, varied from 0.915 to 0.9195,—the first being that of the *hake* oil, the second that of the *haddock*, while the sp. gr. of the purest oil from the common cod was 0.917. De Jongh found the sp. gr. at 63° F. of the pale 0.923, of the light brown 0.924, of the dark brown 0.929. The oil from the cod does not congeal at 14° F., though that of *G. carbonarius* and that of the livers of different species of *Raja* let fall at that temperature a solid fatty matter, supposed to be palmitin. Alcohol dissolves from 2.5 to 6 per cent., water from 0.637 to 1.28 per cent., of different varieties, the pale yielding least to these solvents. (*J. P. C.*, Jan. 1854, p. 39.) The official description is as follows: "A pale yellow, thin, oily liquid, having a peculiar, slightly fishy, but not rancid odor, and a bland fishy taste. Specific gravity: 0.918 to 0.922 at 25° C. (77° F.). Very

slightly soluble in alcohol, but readily soluble in ether, chloroform, or carbon disulphide; also in 2.5 parts of acetic ether." *U. S.* "Specific gravity 0.920 to 0.930. Readily soluble in *ether* and *chloroform*, and slightly soluble in *alcohol* (90 per cent.)." *Br.*

The chemical composition of the glycerides in cod liver oil appears to be very complicated. As palmitic and stearic acids have been isolated, the occurrence of palmitin and stearin is certain. But the so-called "stearin" separating from cod liver oil on cooling contains but little true stearin, as the cod liver stearin has a very high iodine value (113.4, Heyerdahl; 94, Lewkowitsch). The glycerides of the lower fatty acids, such as acetic, butyric, valeric, and capric acids, stated by various authors to occur in cod liver oil, are, according to Salkowski and Steenbuch, secondary products due to the putrefaction of the livers. The researches of Heyerdahl (*Cod Liver Oil and Chemistry*, P. Möller, London, 1895) give as present in the mixed fatty acids about 4 per cent. of palmitic acid, 20 per cent. of *jecoleic acid*, $C_{19}H_{38}O_2$, and 20 per cent. of *therapic acid*, $C_{17}H_{34}O_2$. Besides these the "stearin" contains some unknown unsaturated acid or acids. Heyerdahl states that in the fresh state cod liver oil contains no hydroxy-acids.

A characteristic constituent of cod liver oil is *cholesterol*, which can be isolated by saponifying the oil and exhausting the soap with ether. The quantity of cholesterol, according to Allen and Thomson, is from 0.46 to 1.32 per cent. By reaction with ammonia in distillation the oil yields a volatile alkaloid, *trimethylamine*, C_3H_9N , which has a strong pungent odor, recalling that of herring pickle, of which the same alkaloid is an ingredient. No other official fatty oil yields a similar product. (See *A. J. P.*, xxiv. 343.) Gautier has obtained from cod liver oil the leucamines *butylamine*, *iso-amylamine*, *hexylamine*, and *dihydrolutidine*, and two fixed bases, *aselline*, $C_{25}H_{52}N_4$, and *morruine*, $C_{19}H_{37}N_3$. Aselline was found by its discoverer to be relatively feeble physiologically; morruine, of which about 2 milligrammes are believed to exist in a tablespoonful of ordinary cod liver oil, is affirmed to have the properties of exciting the appetite and acting as a powerful diuretic and diaphoretic. Besides these bases, an acid containing nitrogen has been found. This acid, *morruic acid*, $C_9H_{13}NO_3$, is probably identical with De Jongh's *gaduline*. Some have been disposed to ascribe the virtues of cod liver oil to its iodine and bromine, but these are in too small proportion for much effect, and the oil has produced results which have never been obtained from iodine and bromine themselves. The presence of iodine cannot be detected by the usual tests. It is necessary to convert the oil into a soap, and to carbonize this, before it will give evidence of iodine. The proportion never exceeds 0.05 per cent., or 1 part in 2000, and it is by no means certain

that iodine is always, if ever, present in pure oil. The proportion of iodine present has been investigated by E. C. Stanford (*P. J.* [3], xiv. 353), who found it to be extremely minute, ranging from 0.00138 to 0.00433 per cent., with an average of 0.00322 per cent. The oil is capable of dissolving a larger proportion of iodine, and, if any specimen contain more than 0.05 per cent., there is reason to suspect that iodine has been added. Cod liver oil becomes rancid so easily that it contains varying amounts of free fatty acids, frequently showing their presence, even when freshly rendered. Medicinal oils, however, should not show more than from 0.3 to 0.7 per cent. of free acid, calculated as oleic acid.

Tests of Purity.—In consequence of the great demand for this oil, it has not unfrequently been adulterated with other fixed oils, and occasionally others have been fraudulently substituted for it. The importance, therefore, is obvious of ascertaining some mode of testing its purity and genuineness. The official tests are as follows. "If 1 drop of the Oil be dissolved in 20 drops of chloroform and the solution shaken with 1 drop of sulphuric acid, the solution will acquire a violet-red tint, rapidly changing to rose-red and, finally, brownish-yellow. If a glass rod moistened with sulphuric acid be drawn through a few drops of the Oil, on a porcelain plate, a violet color will be produced. Cod Liver Oil should be only very slightly acid to blue litmus paper which has been previously moistened with alcohol (limit of *free fatty acids*). If 2 or 3 drops of fuming nitric acid be allowed to flow alongside of 10 or 15 drops of the Oil, contained in a watch-glass, a red color will be produced at the point of contact. On stirring the mixture with a glass rod, this color becomes bright rose-red, soon changing to lemon-yellow (distinction from *seal oil*, which shows at first no change of color, and from *other fish oils*, which become at first blue and afterwards brown and yellow). Cod Liver Oil, saponified by alcoholic potassium hydroxide T.S. should show a saponification value of 175 to 185 (see PART III, Test No. 99). If 0.3 Gm. of Cod Liver Oil be dissolved in 10 Cc. of chloroform in a 250 Cc. flask or bottle, and 25 Cc. of a mixture of equal volumes of alcoholic iodine T.S. and alcoholic mercuric chloride T.S. added, and if, after standing for four hours, protected from light, 20 Cc. of potassium iodide T.S. be introduced, and the mixture diluted with 50 Cc. of water, on titrating the excess of iodine with tenth-normal sodium thiosulphate V.S., an iodine value of not less than 140 nor more than 150 should be obtained (see PART III, Test No. 51)." *U. S.* "A drop of *sulphuric acid* added to a few drops of the Oil on a porcelain slab develops a violet coloration. When *nitric acid* is carefully poured into some of the Oil contained in a test-tube, a precipitate of coagulated albumen should be formed at the surface of contact of the two

liquids. No solid fat should separate on exposure of the Oil for two hours to a temperature of 32° F. (0° C.)." *Br.* There is reason to believe that all the oils from the livers of the Gadidæ have analogous properties. They have been indiscriminately used, and upon the results of their employment is based, in part, the present reputation of the medicine. They may, therefore, be considered as in fact one oil, so far as their medicinal use is concerned. Unfortunately, chemistry has yet discovered no perfectly reliable test. The furthest it has gone is to point out certain reactions, which may be considered as evidences of the presence of biliary principles in the oil, thus indicating its hepatic origin. Among these probably the most characteristic is that of Hager and Salkowski, in which a drop of sulphuric acid, added to fresh cod liver oil, on a porcelain plate, causes a centrifugal movement in the oil, and gives rise to a fine violet color, soon passing into a yellowish or brownish red. Sometimes, instead of assuming the violet hue, the color immediately becomes a clear red or a dark brownish-red. This is said to be especially the case with those specimens of the oil which have been prepared by boiling the livers with water. Shark liver oil responds in like manner to the test of sulphuric acid, but is said to have the sp. gr. 0.866, which is much lower than that of any variety of the genuine oil. Rautitz (*Ph. Ztg.*, 1900, 261) states that Norwegian oil prepared by the cold process is often adulterated with the oil from a species of shark, *Scymnus vulgaris*. According to Kremel, fuming nitric acid causes instantly, when agitated with cod liver oil, a pinkish or rose-red color, which soon becomes brown, while no such effect is produced on other animal or vegetable oils. According to Winckler, the oil should afford the odor of herring pickle when heated with potassium hydroxide, lime, and ammonium chloride. But the most reliable tests are the sensible properties of odor and taste. If there be none of the peculiar shoe leather odor and taste; or if a strong lamp oil odor be perceptible, the oil may be suspected. Little of importance can be inferred from the color. Some have been disposed to prefer the dark offensive oil, but our own experience accords with that of those who have found the pale or light brown equally efficient, and for facility of administration and acceptability to the stomach the latter is greatly preferable. It is important that the oil should be secluded from the air, which effects a gradual change, no doubt impairing its efficiency; hence the vessels containing it should be full, and it should be kept in bottles well-stoppered, holding about the quantity generally wanted for use at one time, and not exposed to the sunlight.

Uses.—Cod liver oil has long been popularly employed in Northern Europe in *rheumatic* and *strumous diseases*. It was first brought to the notice of the profession gener-

ally by German practitioners, and had acquired great reputation on the Continent before it was used to any extent in Great Britain. At Manchester, in England, it was employed by the medical profession in the treatment of *chronic rheumatism* and *gout* as early as 1766, but it was not until the appearance of the treatise of Bennett of Edinburgh, in 1841, that it came into general notice in Great Britain and the United States. The diseases in which it has proved most efficient are *chronic rheumatism* and *gout*, and the various morbid affections connected with a serofulous diathesis, such as *external glandular scrofula*, *diseases of the joints and spine*, *carious ulcers*, *tabes mesenterica*, *rickets*, and *phthisis*. It has been found useful also in *chronic cutaneous eruptions*, *lupus*, and *chronic pectoral diseases* not tuberculous, and may be employed with the hope of good in almost all chronic cases in which there is impaired assimilation and nutrition. In *pulmonary consumption* it is of supreme value. It is necessary, however, to persevere for four or six weeks before looking for any decidedly favorable results, though the change does often begin earlier.

As to its mode of action, there has been much difference of opinion. Some consider it merely a nutritive agent, having the advantage over other oleaginous substances of a readier entrance into the system and more easy assimilation. But we cannot agree with this opinion. Other oleaginous substances, certainly not less nutritious, have not been equally efficient, though taken in much larger quantities. If this be the true explanation, persons living chiefly on milk, which abounds in oil, or on fat pork, ought to show a special exemption from serofulous complaints. The probability appears to us to be that, in consequence of some peculiar principle or principles it contains, it exercises a stimulant and alterative influence on the processes of assimilation and nutrition, thereby aiding in the production of healthy tissue.

A tablespoonful (15 Cc.) three or four times a day may be given to adults, a teaspoonful (3.75 Cc.) repeated as frequently to children, which dose may be gradually increased as the stomach will permit, and continued for a long time. It may be taken alone or mixed with some vehicle calculated to conceal its taste and obviate nausea. For this purpose recourse may be had to any of the aromatic waters, to the aromatic tinctures, as the tincture of orange peel, diluted with water, or to a bitter infusion, as that of quassia. It may be given floating on the vehicle, or mixed with it by means of gum or the yolk of egg,¹ with sugar,

in the form of an emulsion. Perhaps the best vehicle, when not contra-indicated, is the froth of porter. Let a tablespoonful of porter be put into the bottom of a glass, upon the surface of this the oil, and over all some of the froth of the porter. A small piece of orange peel may be chewed before and after taking the medicine.² Various other methods have been adopted to conceal or correct the taste and favor administration. Common salt has been recommended, but nothing, perhaps, so effectually destroys the taste as oil of bitter almond, of which one part will answer for 200 parts of the oil. A good plan is to shake strongly, in a flask, one measure of the oil with from one to two of bitter almond water, according to the degree of offensiveness, and to separate the liquids after they have been allowed to stand for twenty-four hours. The oil should be filtered if not quite clear. The medicine is now very largely given in capsules. Dufourmantel prepared a jelly by dissolving half a drachm of ichthyocolla in as little hot water as possible, and then gradually mixing with it a fluidounce of the oil with four drops of the oil of anise, taking care not to exceed the heat of 75° F. (*J. P. C.*, Juin, 1864, p. 72.) Bouchut incorporated the oil with wheat flour, and had this made into bread, which, he said, was in no degree disagreeable. (*N. R.*, Oct. 1873, p. 522.)³ The oil is sometimes applied externally by friction, and in cases of *ascarides* or *lumbrioides* is injected into the rectum. It has been recommended locally in *chronic articular affections*, in various *chronic cutaneous eruptions*, and in *opacity of the cornea* after the subsidence of inflammation. In the last mentioned affection, one or two drops of the oil are applied by means of a pencil to the cornea, and diluted, if found too stimulating, with olive or almond oil.⁴ It is often advantageously combined with lime salts, especially in *rickets*.⁵

to be added *very slowly* to the glycerin with brisk stirring, and the other ingredients added in the order named. *Glycinin* or *Glyceritum Vitell* is made by mixing 45 Gm. of fresh yolk of egg with 55 Gm. of glycerin.

² The following is Carlo Pavesi's formula for deodorized cod liver oil. Cod liver oil 1000 parts, ground roasted coffee 50 parts, animal charcoal 25 parts. Place the ingredients in a flask, which is to be well closed, and digest on a water bath during the space of one hour; then set it aside for three days, occasionally shaking the contents, and filter. This preparation has a peculiar coffee flavor, and is quite pleasant to take, the only objection being the liability to cultivate in the patient a distaste for using coffee as a beverage. (*N. R.*, Jan. 1876.)

³ Phosphorized cod liver oil may be made by dissolving one grain of phosphorus in four fluidounces of cod liver oil.

⁴ *Cod Liver Oil and Ferrous Iodide*.—The following formula is that of a commission appointed by the Netherlands Pharmaceutical Society. Iodine 1 part; Pulverized Iron 1 part; Pale Cod Liver Oil 80 parts. Triturate the pulverized iron in a mortar with the iodine and one-fourth of the oil, and heat the mixture in a water bath, with constant stirring, until the brown color of the iodine has entirely disappeared and given place to a deep purple color, showing that the ferrous iodide has been formed and dissolved. Then add the remainder of the oil, mix carefully, and, after standing, decant into dry bottles, which are to be completely filled. (*N. R.*, Aug. 1876.)

⁵ *Cod Liver Oil with Lactophosphate of Lime*. Take of Cod Liver Oil, 1 pint; Oil of Bitter Almond,

¹ *Glycinin Emulsion of Cod Liver Oil*.—The formula proposed by Close, and at one time largely used by Andrews, Beard, and others, is as follows. Cod Liver Oil 4 fluidounces, Glycinin 9 fluidrachms, Aromatic Spirit of Ammonia 1 fluidrachm, Sherry Wine 2 fluidounces, Diluted Phosphoric Acid 4 fluidrachms, Essence of Bitter Almond (made by dissolving 1 fluidrachm of the volatile oil in half a pint of alcohol) 2 fluidrachms. The cod liver oil is

The *olein* of cod liver oil has been recommended by Arthur Leared, when the oil itself disagrees with the stomach. He has found it to produce the same remedial effects, and to be borne much better. It may be given in the same dose. A solution of quinine in the oil may be made by heating the freshly precipitated alkaloid with the oil, in the proportion of two grains to a fluidounce, by means of a water bath, until the mixture becomes quite clear.

Dose, four fluidrachms (15 Cc.).

OLEUM MYRISTICÆ. U. S., Br.

OIL OF MYRISTICA [Oil of Nutmeg]

(ō'le-ŭm mŷ-ris'ti'cæ)

"A volatile oil distilled from Myristica. It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "The oil distilled from Nutmeg." *Br.*

Volatile oil of Nutmeg; Oleum Myristicæ *Æthereum*, Oleum Nucis Moschati, Oleum Nucis Æthereum; Huile volatile (Essence) de Muscade, *Fr.*; Oleum Macidis, *P. G.*; Aetherisches Muskatöl, Aetherisches Muskatnussöl, *G.*

This oil is obtained from the powdered nutmegs by distillation with water. A better method, according to J. Cloez, is to exhaust the powder with carbon disulphide or ether, distil off the solvent by means of a water bath, and expose the butter-like residue to a current of steam, the vapor being conveyed into a refrigerated receiver, where it condenses. (*J. P. C.*, Fév. 1864.) Schimmel & Co. (1899) state that oil of nutmeg is made from the light, worm-eaten nuts, of which large quantities are rejected in sorting the different qualities in Holland. The worm most strangely robs the nutmeg of its fat oil, while the essential oil remains in the nut in full. Oil of myristica is colorless or of a pale straw color, limpid, lighter than water, soluble in an equal volume of glacial acetic acid, in alcohol and ether, with a neutral reaction, a pungent spicy taste, and a strong odor of nutmeg. It is "a thin, colorless or pale yellow liquid, having a characteristic odor of nutmeg, and a warm, spicy taste. Specific gravity: 0.862 to 0.910 at 25° C. (77° F.). Soluble in an equal volume of alcohol; also soluble in 3 volumes of 90 percent. alcohol. It is dextrogyrate, the angle of rotation varying between +14° and +28° in a 100

Mm. tube, at a temperature of 25° C. (77° F.). When 2 or 3 Cc. of Oil are evaporated on a water-bath, no residue which crystallizes on cooling should be left." *U. S.* "Specific gravity 0.870 to 0.910. The Oil forms a clear solution with its own volume of a mixture of equal parts of absolute alcohol and alcohol (90 per cent.). A little evaporated on a water-bath should not leave a residue which crystallizes on cooling (absence of concrete oil of nutmeg)." *Br.* The mixture of volatile and fixed oils obtained by powerfully expressing nutmegs between heated plates may be separated by agitation with water. Upon standing, the latter deposits a crystalline solid, which was called by Playfair *myristin*. From its solution in alcohol he obtained it in extremely light crystalline scales, which, after repeated crystallization, had still the odor of nutmeg, were fusible at 31° C. (87.8° F.), soluble in the ordinary menstrua of substances of the same class, and, as just said, insoluble in water. By glacial acetic acid it was first colored red. (*P. J.*, March, 1874, 714.) It was identified as the glyceride of myristic acid, $C_{14}H_{28}O_2$, and had, therefore, the formula $C_3H_5(C_{14}H_{27}O_2)_3$. Besides the myristin or solid fat, there is present about an equal amount of a liquid fat containing free acid. The essential oil consists chiefly of pinene with probably some dipentene, also *myristicol*, $C_{10}H_{16}O$, and *myristicin*, $C_{12}H_{14}O_3$. (*Power's Catalogue of Essential Oils*, 1894.) Semmler (*Ber. d. Chem. Ges.*, 1890, 1803) examined an oil of myristica of sp. gr. 0.8611 which contained only terpenes; these boiled at about 50° C. under a pressure of 8 Mm. The oil may be used for the same purposes as myristica.

Dose, five to ten minims (0.3 to 0.6 Cc.), but the oil is not often employed.

OLIVE OIL

(ō'le-ŭm ō-lī'væ)

"A fixed oil expressed from the ripe fruit of *Olea europæa* Linné (Fam. *Oleaceæ*). It should be kept in well-stoppered bottles, in a cool place." *U. S.* "The oil expressed from the ripe fruit of *Olea europæa*, Linn." *Br.*

Sweet Oil; Huile d'Olive, *Fr. Cod.*; Oleum Olivarum, *P. G.*; Olivenöl, *G.*; Olio di olive, *It.*; Aceite de olivas, *Sp.*

Olea europæa, L., *Sp. Pl.* (1753) 8; Willd., *Sp. Plant.* i. 44; B. & T. 172.—This valuable tree is usually from fifteen to twenty feet in height, though sometimes much larger, especially in Greece and the Levant. It has a solid, erect, unequal stem, with numerous straight branches, covered with a grayish bark. The

Oil of Peppermint, Oil of Wintergreen, each, 10 drops; Powdered Gum Arabic, 4 oz. tr.; Powdered Sugar, 6 oz. tr.; Solution of Lactophosphate of Lime (60 gr. to 1 fl. oz.) 6½ fl. oz.; Lime Water, 6½ fl. oz. Mix the gum and sugar in a capacious mortar, and make a smooth mucilage with the lime water and three ounces of the solution of lactophosphate of lime. Add the volatile oils to the cod liver oil, and gradually triturate them with the mucilage until a perfect emulsion is formed. Finally, add the rest of the solution of lactophosphate of lime, and mix thoroughly. *Dose*, from one-half to one fluidounce (15 to 30 Cc.). (*J. T. Shinn, A. J. P.*, March, 1873.)

leaves, which stand opposite to each other on short footstalks, are evergreen, firm, lanceolate, entire, two or three inches in length, with the edges somewhat reverted, smooth and of a dark green color on their upper surface, whitish and almost silvery beneath. The flowers are small, whitish, and disposed in opposite axillary clusters, about half as long as the leaves, and accompanied with small, obtuse, hoary bracts. The fruit, or olive, is a smooth, oval drupe, greenish at first, but of a deep violet color when ripe, with a fleshy pericarp, and a very hard nut of a similar shape. Clusters of not less than thirty flowers yield only two or three ripe olives.

The olive tree, though believed by some to have been originally from the Levant, flourishes at present in all the countries bordering on the Mediterranean, and has been cultivated from time immemorial in Spain, the south of France, and Italy. It begins to bear fruit after the second year, is in full bearing at six years, and continues to flourish for a century. There are forty varieties, distinguished by the form of the leaves and the shape, color, and size of the fruit. The variety *longifolia* of Willdenow is said to be chiefly cultivated in Italy and the south of France, and the *latifolia* in Spain. The latter bears much larger fruit than the former, but the oil is less esteemed. The olive is largely cultivated in the north of Africa, especially in the vicinity of Tunis, and considerable quantities of the oil are exported from that city. (*P. J.*, Sept. 1873, 204.) The tree has been introduced into South Australia, and the oil will probably become of commercial importance there.

Olives are cultivated especially in Spain in the district of Cadiz. Two classes are produced, the one known as the Queen olive, a large olive, which is mostly exported to the United States; the other the Manzanillo, or small olive, which is chiefly consumed in Spain, South America, and Cuba. The olive is largely cultivated in California, where it grows luxuriantly. As long ago as 1897 there were said to be 2,500,000 olive trees in California, but the production of the oil is not very large at present on account of the greater cheapness of labor in France and in Italy.¹ The imports of oil into the United States are annually between eight and nine hundred thousand gallons.

Pickled olives made by soaking green olives first in dilute solution of sodium hydroxide and then in salt water are largely used as an article of food; the ordinary green olive of commerce has been picked before ripening. The

ripe olive, which, in the United States, is chiefly obtained from California, is dark-purple, often almost black, very different in taste from the ordinary unripe pickled fruit, and is said to contain about 50 per cent. of olive oil, so that it affords an excellent method of administering fat.

The leaves and bark of the olive tree have an acrid and bitterish taste, and have been employed as substitutes for cinchona, though with no great success. Attention has been called, in France, to a hydro-alcoholic extract of the leaves, as having considerable febrifuge powers. In the quantity of from ten to twenty grains daily, in divided doses, it has been found useful in preventing the hectic paroxysms. In hot countries, a substance resembling the gum-resins exudes spontaneously from the bark. It was thought by the ancients to possess useful medicinal properties, but is not now employed. Analyzed by Pelletier, it was found to contain resin, a little benzoic acid, and a peculiar principle analogous to gum, which has been named *olivile*. But the fruit is by far the most useful product. In the unripe state it is hard and insupportably acrid, but when macerated in water or an alkaline solution, and afterwards introduced into a solution of common salt it loses these properties, and becomes a pleasant and highly esteemed article of diet. Mannite has been found in all parts of the tree while in vital activity, as in the green leaves and unripe fruit, but cannot be detected in the yellow fallen leaves or in the perfectly ripe fruit. (*A. J. P.*, 1866, p. 179.) The pericarp, or fleshy part of the ripe olive, abounds in a fixed oil, which constitutes its greatest value, and for which the tree is chiefly cultivated in Southern Europe. In the unripe olive a peculiar green substance, together with mannite, has been found by S. de Lutz, both of which disappear as the fruit ripens, being probably converted into oil, which now takes their place. (*J. P. C.*, Juin and Déc. 1862.) The olives ripen from November to March, and the oil is obtained by first bruising them in a mill and then submitting them to pressure. The product varies much, according to the state of the fruit and the circumstances of the process. The best, called *virgin oil*, is obtained from the fruit picked before perfect maturity, and immediately pressed. It is distinguished by its greenish hue. The common oil used for culinary purposes and in the manufacture of the finest soaps is procured from very ripe olives, or from the pulp of those which have yielded the virgin oil. In the latter case the pulp is thrown into boiling water, and the oil removed as it rises. An inferior kind, employed in the arts, especially in the preparation of the coarser soaps, plasters, unguents, etc., is afforded by fruit which has been thrown into heaps, and allowed to ferment for several days, or by the marc left after the expression of the finer kinds of oil, broken up, allowed to ferment, and again introduced into the press. The remarks made under the head of *Oleum Myris-*

¹ There are many varieties of the olive grown in California. J. L. Howland of Pomona, reports the following percentage of oil yielded by each variety as cultivated in California as the result of two years' test: Pendulina, 21; Rubra, 18.5; Oblonga, 18; Misslon, 17.9; Uvaria, 17.5; Nevadillo Blanco, 16.5; Columella, 16.5; Precox, 14; Picholine, 10; Manzanillo, 8.5. For further information concerning the subject the reader is referred to the various Proceedings of the California State Convention of Olive Growers.

tice in relation to the extraction of the fixed oil by means of solvents are applicable also to olive oil.

Olive oil is imported in glass bottles, or in flasks surrounded by a kind of net-work of grass and usually called Florence flasks. The best comes from Southern France, where much care is exercised in the choice of the fruit.

Properties.—The pure oil is an unctuous liquid, or “a pale yellow or light greenish-yellow oily liquid, having a slight peculiar odor, and a nut-like, oleaginous taste, with a faintly acid after-taste. Specific gravity: 0.910 to 0.915 at 25° C. (77° F.). Very sparingly soluble in alcohol, but readily soluble in ether, chloroform, or carbon disulphide.” *U. S.*

The concrete portion, about 28 per cent. of the oil, which separates at a freezing temperature, consists chiefly of the glyceride of *palmitic acid*, $C_{15}H_{31}O_2$, together with a smaller amount of *arachidic acid*, $C_{20}H_{41}O_2$ (stearic acid is stated by Hehner and Mitchell to be absent entirely); the liquid portion is essentially olein, $C_{18}H_{35}(O.C_{18}H_{35}O)_3$, with a small amount (seven parts for ninety-three of olein) of the glyceride of the less saturated linolic acid. According to Braconnot, the oil contains 72 per cent. of olein and 28 of palmitin. A small quantity of *cholesterin*, $C_{26}H_{44}O$, has also been found in the oil. Olive oil is solidified by nitrous acid and mercuric nitrate, and converted into a peculiar fatty substance, called *elaidin*. The olein of all oils which have not the drying property undergoes the same change when acted on by nitrous acid.

The greenish color is owing to the presence of a trace of chlorophyll, and a trace of *cholesterin* is also extracted by repeated agitation with glacial acetic acid.¹

Olive oil, when exposed to the air, is prone to become rancid, acquiring a disagreeable odor, a sharp taste, and a thicker consistence; it also loses its color, and the change is promoted by heating it. It is officially tested as follows: “When cooled to from 8° to 10° C. (46.4° to 50° F.), the Oil becomes somewhat cloudy from the separation of crystalline particles, and at 0° C. (32° F.), it forms a whitish, granular mass. If 2 Cc. of Olive Oil be shaken vigorously with an equal volume of nitric acid (sp. gr. 1.37), the Oil should retain a light yellow color, not becoming orange or reddish-brown, and after standing for six hours should change into a yellowish-white solid mass and an almost colorless liquid (absence of appreciable quantities of *cotton seed oil* and *most other seed oils*). If 5 Cc. of the Oil be thoroughly shaken in a test-tube with 5 Cc. of an alcoholic solution of silver nitrate (made by dissolving 0.1 Gm. of silver nitrate in 10 Cc. of alcohol and adding 2 drops of nitric acid), and the mixture be heated for about five minutes in a water-bath, the Oil should retain its original pale color, not becoming reddish or brown, nor

should any dark color be produced at the line of contact of the two liquids (absence of more than about 5 percent. of *cotton seed oil*). If 2 Cc. of the Oil be mixed in a test-tube with 2 Cc. of equal volumes of amyl alcohol and carbon disulphide containing 1 percent. of sulphur in solution, and the test-tube be immersed to one-third or one-half its depth in boiling salt water, no reddish color should develop in from ten to fifteen minutes (absence of *cotton seed oil*). If 2 Cc. of the Oil be mixed with 1 Cc. of hydrochloric acid (sp. gr. 1.18) containing 1 percent. of sugar, and the mixture be shaken for half a minute and allowed to stand for five minutes, and then 3 Cc. of water added and the whole again shaken, the acid layer should not show a pink color (absence of *sesame oil*). Olive Oil, saponified by alcoholic potassium hydroxide T.S. should show a saponification value of 191 to 195 (see PART III, Test No. 99). If 0.3 Gm. of Olive Oil be dissolved in 10 Cc. of chloroform, in a 250 Cc. bottle or flask, and 25 Cc. of a mixture of equal volumes of alcoholic iodine T.S. and alcoholic mercuric chloride T.S. added, and if, after standing for four hours, protected from light, 20 Cc. of potassium iodide T.S. be introduced, and the mixture diluted with 50 Cc. of water, on titrating the excess of iodine with tenth-normal sodium thiosulphate V.S., an iodine value of not less than 80 nor more than 88 should be obtained (see PART III, Test No. 51).” *U. S.* “At 50° F. (10° C.) it is liable to become of a pasty consistence, and at 32° F. (0° C.) to form a nearly solid granular mass. If 10 cubic centimetres of the Oil be shaken with 2 cubic centimetres of a reagent prepared by dissolving 1 gramme of *silver nitrate* in 100 cubic centimetres of *absolute alcohol*, with the addition of 20 cubic centimetres of *ether* and one drop of *nitric acid*, no blackening should occur when the mixture is heated on a water-bath for ten minutes (absence of *cotton-seed oil*).” *Br.* It is frequently adulterated with the cheaper fixed oils, especially with cotton seed oil, arachis oil, sesame oil and poppy seed oil; the adulteration may sometimes be detected by reducing the temperature to the freezing point. As other oils are less readily congealed than is the olive oil, the degree of its purity will be indicated by the degree of concretion. Another mode has been indicated by Poutet, founded on the property possessed by mercuric nitrate of solidifying the oil of olives, without a similar influence upon other oils. Six parts of mercury are dissolved at a low temperature in seven and a half parts of nitric acid of the sp. gr. 1.35, and this solution is mixed with the suspected oil in the proportion of one part to twelve, the mixture being occasionally shaken. If the oil is pure, it will be converted after some hours into a yellow solid mass; if it contains a minute proportion, even so small as a twentieth, of poppy or cotton seed oil, the resulting mass will be much less firm, and a tenth will prevent a greater degree of consistence than oils usually

¹For discussion of the spectra of olive oil, see *P. J.*, 3d series, vii. 22, 116.

acquire when they concrete by cold. Lwowkowsitch (*Chemical Analysis of Oils, Fats, and Waxes*, 2d ed., 1898, 462) says that the color reactions proposed by various authors are altogether unreliable and yield no definite results, with the exception of the color test (Baudoin's test, see *Oleum Sesami*) for sesame oil and perhaps Bechi's and Millian's or Halphen's for cotton seed oil (see below). For a method of detecting the oil of *arachis* (ground nut oil) in olive oil, see *J. P. C.*, Janv. 1872, 48. The Bureau of Chemistry of the U. S. Agricultural Department investigated 157 samples purchased throughout the country; 11 out of 72 samples of French oil, 10 out of 67 samples of Italian oil, and 2 out of 15 samples of California oil, were found to be impure. The same authorities conclude that but little cotton seed oil is found in olive oil as imported, but is added to it in the United States. Arachis oil, however, which is produced in large quantities in Marseilles, was found in numerous samples of imported olive oil. According to Tambon, the present-day adulterations do not consist in the addition of a single cheaper oil, but of ingeniously prepared mixtures of different oils in such proportions to each other that on analysis it becomes difficult or impossible to distinguish the adulterated from the genuine oil by the chemical and physical constants accepted for the latter. The chief adulterants are benne, peanut and cotton seed oil. Of these, benne is easily recognized; for peanut oil there is as yet no reliable color reaction, and while Bechi's reaction may, under certain conditions, answer well for the detection of cotton seed oil, this, under others, has also proven unreliable. (*Ph. Ztg.*, 1904, 104.) According to Kreis and Grob (*S. W. P.*, 1901, 88) Billier's test is very sensitive. It is carried out by shaking the suspected oil with a solution of resorcinol in benzene and afterwards with nitric acid. Olive oil under these circumstances remains unchanged in color, cotton seed and nut oil become red violet and maw seed oil is turned brown red. Bechi's test for ascertaining the admixture of cotton seed oil with olive oil has received the approval of the Commission of Florence after most exhaustive experiments, and is as follows. One grain (0.065 Gm.) of silver nitrate is dissolved in fifteen minims (0.9 Cc.) of water, and six and a half fluidounces (200 Cc.) of alcohol are added. Two fluidounces (or 60 Cc.) of ether may be added to render the solution more easily miscible with the oil, but it is not absolutely necessary. A solution of eighty-five parts of amyl alcohol and fifteen parts of rape seed oil is prepared. These reagents should not be kept on hand any length of time. To ten Cc. of the oil to be examined one Cc. of the solution of silver nitrate is added, and then from eight to ten Cc. of the amyl alcohol reagent; the mixture is agitated strongly, and heated on a water bath for five or ten minutes. In the case of pure oils the color is unaltered by the addition of

the reagents; if cotton seed oil be present, a brownish color or turbidity, varying from a light brown to a deep maroon or black (according to the extent of the adulteration), will be produced. (*A. J. P.*, 1887.) See also the official silver nitrate test. Millian's test is a modification of the foregoing. If the fatty acids instead of the oil itself are treated with the same reagents, the same reduction of the silver salts occurs and the same brown color as in the Bechi test. Halphen's test with a mixture of amyl alcohol and carbon disulphide containing about 1 per cent. of sulphur in solution is now regarded as the most distinctive for cotton seed oil. For details see the official test.

Uses.—Olive oil is nutritious and mildly laxative, and is occasionally given as a feeble purgative in cases of irritable intestines. Taken into the stomach in large quantities, it serves to involve acrid and poisonous substances and mitigate their action. It has also been recommended as a remedy for worms, and is a very common ingredient in laxative enemata. The value of large doses of olive oil in the treatment of gall stones, as originally suggested by Kennedy, has received much confirmation, and the experiments of Rosenberg go to show that the remedy does increase not only the amount but also the fluidity of the bile. From six to seven ounces of it may be given in from four to eight portions, during not less than three hours, in aromatized emulsion. Externally applied, it is useful in relaxing the skin and in sheathing irritated surfaces from the action of the air, and it is much employed as a vehicle or diluent of more active substances; but the most extensive use of olive oil in pharmacy, is as a constituent of liniments, ointments, cerates, and plasters.

Dose, as a laxative, from one to two fluidounces (30 to 60 Cc.).

OLEUM PHOSPHORATUM. *Br.*

PHOSPHORATED OIL

(ô'le-ŭm phôs-phô-ră'tŭm)

Hulle phosphorée, *Fr. Cod.*; Liniment phosphoré, *Fr.*; Phosphorhaltiges Oel, *G.*; Aceite fosforado, *Sp.*

"Heat Almond Oil in a porcelain dish to about 300° F. (149° C.), and keep it at this temperature for about fifteen minutes, then let it cool, and filter it through paper. Put ninety-nine parts by weight into a stoppered bottle, capable of holding rather more than this quantity, and add to it one part by weight of dry

Phosphorus. Immerse the bottle in hot water until the mixture has acquired the temperature of 180° F. (82.2° C.), removing the stopper two or three times to allow the escape of expanded air; then shake until the Phosphorus is entirely dissolved." *Br.*

Phosphorated oil was not retained in the U. S. P. (8th Rev.). The process of the U. S. P. 1890 is appended.¹

The U. S. 1890 process did not differ essentially from that of the Br. Pharm. Both are one per cent. solutions; the British formerly contained but 0.75 per cent.² The object of heating the oil is to expel air and traces of water, which would aid in oxidizing the phosphorus. The ether not only assists in the preservation of the finished preparation, but is also of use in rendering the oil less disagreeable to the taste. E. R. Squibb passes a current of carbon dioxide through the oil contained in the bottle in which it is to be kept, to expel the air and prevent oxidation. This is a clear and colorless or but slightly colored oil, not phosphorescent in the dark, and having the odor and taste of phosphorus quite distinctly. It should be perfectly free from any particles of undissolved phosphorus. It may be administered in the form of an emulsion, like the official almond emulsion, and flavored with oil of bitter almond, or preferably in capsules; each minim contains about 1-115 of a grain of phosphorus.

Dose, one to three minims (0.06 to 0.2 Cc.).

OLEUM PICIS LIQUIDÆ. U. S.

OIL OF TAR

(ô'le-üm pî'cis liq'ü-dæ)

"A volatile oil distilled from tar." *U. S.*

Hulle volatile de Goudron, *Fr.*; Theeröl, *Pechöl, G.*

This oil is prepared by distilling wood tar, the residue left in the still being known as

¹ *Oleum Phosphoratum*. U. S. 1890. *Phosphorated Oil*.—"Phosphorus, one gramme [or 15.5 grains]; Expressed Oil of Almond, Ether, each, a sufficient quantity, to make one hundred grammes [or 3 ounces av., 231 grains]. Introduce a sufficient quantity of Expressed Oil of Almond into a flask, heat it on a sand-bath to 250° C. (482° F.), and keep it at that temperature for fifteen minutes. Then allow it to cool, and filter it. Put ninety grammes [or 3 ounces av., 76 grains] of the filtered Oil together with the Phosphorus, previously well dried by filtering paper, into a dry, tared bottle capable of holding about one hundred and twenty cubic centimeters [or 4 fluidounces, 28 minims], insert the stopper, and heat the bottle in a water-bath until the Phosphorus melts. Then agitate it until the Phosphorus is dissolved, allow it to cool, add enough Ether to make the mixture weigh one hundred grammes [or 3 ounces av., 231 grains], and agitate it again. Lastly transfer the solution to small glass-stoppered vials, which should be completely filled and kept in a cool and dark place." *U. S.* 1890.

² It is often desirable to be acquainted with the degree of solubility of phosphorus in the different fixed oils in ordinary use, in reference to its exhibition as medicine. The following list is taken from the *Journal de Pharmacie* (Fév. 1869, p. 94), where it is given on the authority of M. C. Merc. The oils of sweet almonds, of olives, of sesamum, and of ground nuts will retain, at common temperatures, 1-80 of their weight of phosphorus. It may even

pitch. It represents thoroughly the medicinal properties of tar, and is preferable on account of its less offensive taste. (See *Pix Liquidæ*.) It is officially described as "an almost colorless liquid when freshly distilled, but soon acquiring a dark reddish-brown color, and having a strong, tarry odor and taste. Specific gravity: about 0.965 at 25° C. (77° F.). It is readily soluble in alcohol, the solution showing an acid reaction to litmus paper." *U. S.*

Dose, one to five minims (0.06 to 0.3 Cc.), administered in capsule or in emulsion.

OLEUM PIMENTÆ. U. S., Br.

OIL OF PIMENTA [Oil of Allspice]

(ô'le-üm pi-mën'tæ)

"A volatile oil distilled from Pimenta, yielding, when assayed by the process given below, not less than 65 percent., by volume, of eugenol. It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "The oil distilled from Pimento." *Br.*

Oleum Amomi; Oil of Pimento; Huile volatile (Essence) de Piment de la Jamaïque, *Fr.*; Nelkenpfefferöl, *Pimentöl, G.*

The berries yield from 1 to more than 4 per cent. of the volatile oil, which as found in commerce is brownish-red, and has the odor and taste of pimenta, though warmer and more pungent. It has a slightly acid reaction. "A colorless, yellow, or reddish liquid, having a strong, aromatic odor of allspice, and a pungent, spicy taste. Specific gravity: 1.033 to 1.043 at 25° C. (77° F.). With 90 percent. alcohol it is miscible in all proportions. It is also soluble in 2 volumes of 70 percent. alcohol. When mixed with an equal volume of a concentrated solution of sodium hydroxide, it forms a semi-solid mass." *U. S.* "Yellow or yellowish-red when recently distilled, but gradually becomes darker. It has the odor and taste of pimento. Specific gravity not below 1.040. It should be converted into a semi-solid mass when shaken with an equal volume of strong solution of ammonia." *Br.* It consists, like oil of cloves, of two distinct portions, one a sesquiterpene, C₁₅H₂₄, and the other a phenol, *eugenol*, capable of extraction by shaking out with alkaline hydroxide solution. They may be separated by distilling the oil from potassium hydroxide solution. After the hydrocarbon is distilled off the phenol may be obtained by liberation from its combination with sulphuric acid and distilling. It is readily recognized as *eugenol*, so that oil of pimenta is analogous in

descend to 1-78 for almond and ground nut oils; but it is not prudent, in practice, to keep too near the limits of saturation. The oils of colza and flaxseed, brown cod liver oil, and neat's foot oil, retained 1-70 of their weight, even after eight days' exposure in a cellar. Castor oil is far removed from these figures, 105 parts of it being required to dissolve one part of phosphorus. The author has observed no sensible difference in the dissolving power of overheated and not overheated oils.

its constitution to oil of cloves (see *Oleum Caryophylli*). Nothing is known of the constituents which give oil of pimenta its characteristic odor. The U. S. P. (8th Rev.) furnishes an assay to determine the proportion of eugenol as follows:

Assay for Eugenol. U. S. (8th Rev.).—"Introduce into a flask with a long neck (graduated in tenths) 10 Cc. of the Oil of Pimenta and 100 Cc. of potassium hydroxide T.S., and shake the mixture for five minutes. When the liquids have separated completely, add sufficient potassium hydroxide T.S. to raise the lower limit of the oily layer to the zero mark of the scale, and note the volume of residual liquid, which should not measure more than 3.5 Cc., indicating the presence of at least 65 percent. of eugenol." U. S. Oil of pimenta is given for the same purposes as are the other stimulant aromatic oils.

Dose, from three to six minims (0.2 to 0.4 Cc.).

OLEUM PINI. Br.

OIL OF PINE

(ō'le-ŭm pī'nī)

"The oil distilled from the fresh leaves of *Pinus Pumilio*, *Haenke*." Br.

Pine Needle Oil; Latschenkieferöl, Krummholzöl, G.

The British Pharmacopeia 1898 replaced fir wood oil by making oil of pine official. This was largely due to the investigations of J. C. Umney (*P. J.*, 1895, 161, 173, 542), who found that the *Pinus Pumilio* (Mountain Pine) furnished an oil of fairly constant character and superior to that from the *Pinus sylvestris* (Scotch Fir) of the Br. Ph. 1885. It is described as "colorless or nearly so, with a pleasant aromatic odor and pungent taste. Specific gravity 0.865 to 0.870. It should rotate the plane of a ray of polarized light from 5° to 10° to the left at 60° F. (15.5° C.) in a tube 100 millimetres long. Not more than 10 per cent. should distil below 329° F. (165° C.)." Br. It resinifies on exposure, and in medicinal qualities resembles oil of turpentine, but is milder. Pine oil contains *lævo-pinene*, *lævo-phellandrene*, *sylvestrene*, *bornyl acetate*, and in the last portions of the distillate, *cadinene*. (Gildemeister and Hoffmann, *Aetherische Oele*, p. 338.) It is supposed that the pine oil owes its odor to the presence of the acetic ester of borneol, which is ordinarily present to the amount of about 3.5 per cent., and Schimmel & Co. (*Schim. Rep.* for Oct. 1897) found in a sample of American fir oil as much as 12.1 per cent. It has been used internally in the treatment of *chronic rheumatism* in doses of from ten to twenty minims (0.6 to 1.3 Cc.), but it is especially employed for the purposes of inhalation. The leaves of the *Pinus sylvestris*, with those of other European firs and pines, by pounding are converted into a fibrous substance,

known as *fir wool* (*Fichtenwolle*), which is much used in Germany as a local application in *chronic rheumatism*, the affected part being enveloped in a thick batting of the fir wool, which is also sometimes made into clothing for rheumatic persons. An extract of the leaves is also sold under the name of *fir wool extract*, for use in rheumatism.

OLEUM RICINI. U. S., Br.

CASTOR OIL

(ō'le-ŭm ric'ī-nī)

"A fixed oil expressed from the seed of *Ricinus communis* Linné (Fam. *Euphorbiaceæ*). It should be kept in well-stoppered containers." U. S. "The oil expressed from the seeds of *Ricinus communis*, Linn." Br.

Hulle de Ricin, *Fr. Cod.*; Oleum e semine Ricini, *Fr.*; Oleum Ricini, *P. G.*; Ricinusöl, *G.*; Olio di ricino, *It.*; Aceite de ricino; Oleum Palmae Christi, *Sp.*

Ricinus communis, Willd., *Sp. Plant.* iv. 564. The castor oil plant, or *palma Christi*, attains in the East Indies and Africa the character of a tree, and rises sometimes thirty or forty feet. In the temperate latitudes of North America and Europe it is annual, though Achille Richard saw in the south of France, in the vicinity of Nice, on the sea coast, a small wood consisting entirely of what he supposed to be this species of *Ricinus*.¹ The following description applies to the plant as cultivated in cool latitudes. The stem is of vigorous growth, erect, round, hollow, smooth, glaucous, somewhat purplish towards the top, branching, and from three to eight feet or more in height. The leaves are alternate, peltate, palmately six to eleven lobed, the lobes acute or acuminate and serrate, smooth on both sides, and of a bluish-green color. The flowers are monœcious, stand upon jointed peduncles, and form a pyramidal terminal raceme, of which the lower portion is occupied by the male flowers, the upper by the female. Both are destitute of corolla. In the male flowers the calyx is divided into five oval, concave, pointed, reflected, purplish segments, and encloses numerous stamens, united into fasciculi at their base. In the female the calyx has three or five narrow lanceolate segments, and the ovary, which is roundish and three-sided, supports three linear, reddish stigmas, forked at their apex. The fruit is a roundish, glaucous capsule, with three projecting sides, covered with tough spines, and divided into three cells, each containing one seed, which is expelled by the bursting of the capsule. This species of *Ricinus* is a native

¹ While at Montpellier, in France, in the spring of 1861, Geo. B. Wood was assured by Martius, professor of botany in the university of that city, that the species seen by Richard was not the *Ricinus communis*, but the *Ricinus africanus*, also that all the plants of the genus *Ricinus* growing wild on the borders of the Mediterranean were the *R. africanus*.

of the East Indies and Northern Africa, naturalized in the West Indies, and cultivated in various parts of the world, in few countries more largely than in the Middle and Western United States. The flowers appear in July, and the seeds ripen successively in August and September. A decoction or poultice of the leaves is sometimes used as a local galactagogue, and an infusion has been given internally for a similar purpose. (*L. L.*, Dec. 1859.)

1. THE SEEDS.—These are about as large as a small bean, oval, compressed, obtuse at the extremities, very smooth and shining, and of a grayish or ash color, marbled with reddish brown spots and veins. At one end of the seed is a small yellowish tubercle, from which an obscure longitudinal ridge proceeds to the opposite extremity, dividing the side upon which it is situated into two flattish surfaces. In its general appearance the seed is thought to resemble the insect called the *tick*, the Latin name of which has been adopted as the generic title of the plant. Its variegated color depends upon a very thin pellicle closely investing a hard, brittle, blackish, tasteless, easily separated shell, within which is the kernel, highly oleaginous, of a white color, and of a sweetish taste succeeded by a slight degree of acrimony. The seeds easily become rancid, and are then unfit for the extraction of the oil, which is acrid and irritating. In 100 parts Geiger found, exclusive of moisture, 23.82 parts of envelope, and 69.09 of kernel. These 69.09 parts contained 46.19 of fixed oil, 2.40 of gum, 20.00 of starch and lignin, and 0.50 of albumen. Henry Bower could find no starch, but separated from the seeds an albuminoid principle, which acted with amygdalin and water like emulsin, producing the odor of oil of bitter almond, though in a less degree. (*A. J. P.*, xxvi. 208.) It is highly probable that it is this principle which, acting as an enzyme on the oily matter of the seeds, gives rise to changes in its nature which render them rancid. (See *Olea Fixa*, p. 810.) G. J. Scattergood found the odor of castor oil to be developed in the beans when bruised with water, and much more powerfully in those long kept than in the fresh. The water distilled from the seeds has a peculiar nauseous odor, quite distinct from that of the oil. (*Ibid.*, xxvii. 207.)

Taken internally the seeds are powerfully cathartic, and often emetic. Two are sufficient to purge with great violence, and three have produced fatal gastro-enteritis in the adult. After expression of the oil, and treatment with pure alcohol, Calloud found the residue to be powerfully emetic in the quantity of 30 grains, taken in two doses. (*J. P. C.*, 3e sér., xiv. 190.) According to Guibourt, the toxic property pervades the whole kernel, the integuments being inert. The experiments of Scattergood, who found that the water distilled from the seeds is emetic and cathartic, would seem to show that the active principle is volatile, but the researches of Stillmark indicate that it is an

enzyme, *ricin*, which is a so-called phytalbumose and has been obtained as a white amorphous powder, and is best dissolved in a 10 per cent. salt solution. The aqueous solution of the pure ricin has a neutral reaction. It is a violent poison. E. L. Boerner (*A. J. P.*, 1876, p. 481) obtained butyric acid by macerating the exhausted marc of the seeds with water until decomposed.

2. THE OIL.—This may be extracted from the seeds in three ways: 1, by decoction; 2, by expression; 3, by the agency of alcohol or other solvent.

The process by decoction, which has been practised in the East and West Indies, consists in bruising the seeds, previously deprived of their husk, and then boiling them in water. The oil, rising to the surface, is skimmed or strained off, and afterwards again boiled with a small quantity of water to dissipate the acrid principle. The seeds, it is said, are sometimes roasted, to increase the product. But by a temperature much above 212° F. the oil is rendered brownish and acrid, and the same result takes place in the second boiling, if care is not taken to suspend the process soon after the water has been evaporated; hence it happens that the West India oil has generally a brownish color, an acrid taste, and irritating properties.

The oil is obtained in this country by expression. The following, we have been informed, are the outlines of the process usually employed by those who prepare it on a large scale. The seeds, having been thoroughly cleansed from the dust and fragments of the capsules with which they are mixed, are conveyed into a shallow iron reservoir, where they are submitted to a gentle heat insufficient to scorch or decompose them, and not greater than can be readily borne by the hand. The object of this step is to render the oil sufficiently liquid for easy expression. The seeds are then introduced into a powerful hydraulic press. A whitish oily liquid is thus obtained, which is transferred to clean iron boilers supplied with a considerable quantity of water. The mixture is boiled for some time, and, the impurities being skimmed off as they rise to the surface, a clear oil is at length left upon the top of the water, the mucilage and starch having been dissolved by this liquid, and the albumen coagulated by the heat. The latter ingredient forms a whitish layer between the oil and the water. The clear oil is now carefully removed, and the process is completed by boiling with a minute proportion of water, and continuing the application of heat until aqueous vapor ceases to rise, and until a small portion of the liquid, taken out in a vial, continues perfectly transparent when it cools. The effect of this last operation is to clarify the oil, and to render it less irritating by driving off the acrid volatile matter. But much care is requisite not to push the heat too far, as the oil then acquires a brownish hue and an acrid peppery taste. After the completion of the process, the oil is put into barrels

and sent into the market.¹ See article on the preparation of castor oil (*A. J. P.*, 1879, p. 481).² There is reason, however, to believe that much of the American oil is prepared by merely allowing it to stand for some time after expression, and then drawing off the supernatant liquid. One bushel of good seeds yields five or six quarts, or about 25 per cent. of the best oil. If not carefully prepared, it is prone to deposit a sediment upon standing, and the apothecary may find it necessary to filter it through coarse paper before dispensing it. Perhaps this may be owing to the plan just alluded to of purifying the oil by rest and decantation. We have been told that the oil in barrels usually deposits in cold weather a copious whitish sediment, which is redissolved when the temperature rises. A large proportion of the oil consumed in the eastern section of the Union has been derived, by the way of New Orleans, from Illinois and the neighboring States, where it has been at times so abundant that it has been used for burning in lamps and for lubricating machinery.³

The process for obtaining castor oil by means of alcohol has been practised in France, but the product is said to become rancid more speedily than that procured in the ordinary mode. Such a preparation has been employed in Italy, and is asserted to be less disagreeable to the taste, and more effective, than the common oil obtained by expression. According to Parola, an ethero-alcoholic extract and an ethereal or alcoholic tincture of the seeds operate in much smaller doses than the oil, and with less disposition to irritate the bowels or to cause vomiting. (See *Am. J. M. S.*, N. S., xiii. 143.)

¹ Owing to the presence of ricin, "*castor pomace*" or the oil cake obtained by the extraction of castor oil, is unfit for animal food. For the process of removing the poisonous principle see *P. J.*, lxviii. 213.

² For a particular account of the mode of cultivating the castor oil plant and preparing the oil in the Western States, see a paper by Procter in *A. J. P.* (xxvii. 99).

³ *Italian Castor Oil.*—The castor oil plant is cultivated throughout Italy, but especially in the neighborhood of Verona, where the oil is prepared with great care and is remarkably free from the peculiar odor and taste which render this medicine so repulsive to many palates. As it is highly desirable, for certain purposes, that the oil should be as free from these properties as possible, though as a mere purgative perhaps less powerful when deprived of them, it is a point worthy of investigation, why it is that the Italian oil is superior to most if not all other commercial varieties of the oil in these respects. The following facts in relation to the mode of preparing the oil practised at Verona, published by H. Groves of Florence, acquire on this account a special value. One point of importance is that the seeds are used fresh, as the oil rapidly becomes rancid in them when kept. Another fact is that the seeds are entirely deprived of their coating before being submitted to pressure. This is effected by passing them between two revolving wooden rollers, with a winnowing machine beneath, and, to secure the complete absence of integument, they are afterwards assorted by the hand, all being rejected which are not perfectly decorticated. They are then put into hempen bags, which are arranged in layers with a sheet of iron heated to 90° F. between them, so as to enable the oil to flow. Lastly, they are submitted to pressure in hydraulic presses. The oil which now flows is of the finest quality. An inferior kind is obtained by pressing the marc at a somewhat higher heat. (*P. J.*, Oct. 1866.)

Properties.—Pure castor oil is a thick, viscid, colorless liquid, with little or no odor, and a mild though somewhat nauseous taste, followed by a slight sense of acrimony. As found in commerce it is often tinged with yellow and has an unpleasant odor, and parcels are sometimes, though rarely, met with of a brownish color and hot acrid taste. It does not readily congeal by cold. When exposed to the air it slowly thickens, without becoming opaque. When exposed to the air in a thin layer, it slowly dries to a varnish-like film. It is heavier than most of the other fixed oils, its sp. gr. having been stated to be 0.969 at 55° F. or "0.945 to 0.965 at 25° C. (77° F.)." *U. S.* It differs also from most other fixed oils in being soluble in all proportions in cold absolute alcohol. "Soluble in an equal volume of alcohol, and in all proportions in absolute alcohol or in glacial acetic acid; also soluble, at 25° C. (77° F.), in 3 times its volume of 92.5 percent. alcohol (absence of more than about 5 percent. of most other fixed oils). With an equal volume of petroleum benzin, it forms at 15° C. (59° F.) a turbid mixture, but at 17° C. (62.6° F.) it yields a clear solution. When cooled to 0° C. (32° F.) it becomes turbid, with the separation of crystalline flakes, and at about -18° C. (-0.4° F.) it congeals to a yellowish mass. If 3 Cc. of the Oil be shaken for a few minutes with 3 Cc. of carbon disulphide and 1 Cc. of sulphuric acid, the mixture should not acquire a blackish-brown color (absence of foreign oils). Castor Oil saponified by alcoholic potassium hydroxide T.S. should show a saponification value of 179 to 180 (see PART III, Test No. 99). If 0.3 Gm. of Castor Oil be dissolved in 10 Cc. of chloroform, in a 250 Cc. bottle or flask, and 25 Cc. of a mixture of equal volumes of alcoholic iodine T.S. and alcoholic mercuric chloride T.S. added, and if, after standing for eight hours, protected from light, 20 Cc. of potassium iodide T.S. be introduced, and the mixture diluted with 50 Cc. of water, on titrating the excess of iodine with tenth-normal sodium thiosulphate V.S., an iodine value of not less than 86 nor more than 89 should be obtained (see PART III, Test No. 51)." *U. S.* "Specific gravity 0.950 to 0.970. Soluble in an equal volume of absolute alcohol, and in five times its volume of alcohol (90 per cent.). It dries slowly to a varnish when exposed to the air in a thin layer. If 3 cubic centimetres of the Oil be shaken with an equal volume of carbon bisulphide, and 1 cubic centimetre of sulphuric acid be then added, the mixture on being shaken should not become brown (absence of various fixed oils, including cotton-seed oil). Equal volumes of Castor Oil and petroleum spirit do not yield a clear mixture if kept at 60° F. (15.5° C.), but they yield a perfectly clear solution if other fixed oils be present." *Br.*

Weaker alcohol, of the sp. gr. 0.8425, takes up about three-fifths of its weight. It has been supposed that adulterations with other fixed

oils might thus be detected, as the latter are much less soluble in that fluid, but Pereira has shown that castor oil has the property of rendering a portion of other fixed oils soluble in alcohol, so that the test cannot be relied on. (*P. J.*, ix. 498.) Such adulterations, however, are seldom practised in this country.¹ Castor oil is soluble also in ether, and in its weight of glacial acetic acid. Its proximate composition² has been repeatedly investigated. The bulk of it is *ricinolein*,³ $\text{C}_{35}\text{H}_{55}(\text{C}_{18}\text{H}_{35}\text{O}_2)_3$, which is the *ricinoleic acid* ($\text{C}_{18}\text{H}_{35}\text{O}_2$) glyceride. At the same time it also contains a small quantity of tristearin and of the glyceride of dihydroxystearic acid, together with from 0.30 to 0.37 per cent. of unsaponifiable matter. Ricinoleic acid, as obtained from the decomposition of the glyceride, is a viscid oil, which solidifies below 0°C ., does not solidify in contact with the air by absorption of oxygen, and is not homologous with oleic or linoleic acid, neither of which is found in castor oil. On warming with 1 part of starch and 5 parts of nitric acid (sp. gr. 1.25) castor oil thickens, owing to the formation of *ricinelaidin*. From this *ricinelaidic acid* may be obtained in brilliant crystals. Ricinoleic acid is converted by potassium hydroxide into caprylic alcohol and sebatic acid, with disengagement of hydrogen, and the same products are obtained by the reaction of potassium hydroxide with the oil itself. (See *J. P. C.*, Août, 1885, 113.) Its purgative property is

¹ Cohesion figures as a means of testing liquids. A mode of testing oily or resinous liquids has been proposed by Charles Tomlinson, which is applicable to this oil, and may succeed when purely chemical methods fail. When one liquid is dropped on the surface of another, there are often curious figures produced, as the drop spreads out on the surface of the liquid upon which it falls, occasioned by the conflict between the cohesion of the drop and the forces which cause its diffusion. These the author called *cohesion figures*. As a rule, each liquid has its own characteristic figures, which are modified by the admixture of other liquids, and thus the means are afforded of testing not only the identity of any suspected liquid, but also its purity. To one not acquainted with the characteristic cohesion figures, it would be sufficient to try the experiment with a specimen known to be pure, and then to compare with the figure it forms, those formed by the specimen to be tested. The experiment should always be made under precisely similar circumstances. In reference to castor oil, it should be dropped from the end of a glass rod upon the surface of perfectly clear water, in a glass vessel scrupulously clean, as any imperfection in these respects might interpose a physical impediment to the success of the experiment. (*Chem. News*, Feb. 13, 1864, p. 79. See also *A. J. P.*, July, 1864.)

Effect on light.—Another test for castor oil is its influence on polarized light. The fixed oils generally have little or no power. Castor oil deviates the plane of polarization to the right, but loses this property if heated to 270°C . (518°F .). (*J. P. C.*, Nov. 1861, p. 339.)

² When distilled *in vacuo* it yields at first about one-third of its volume of nearly pure ananthol, and after this, with great rise of temperature, a crystallizing body belonging to the oleic acid group and having the formula $\text{C}_{12}\text{H}_{22}\text{O}_2$. (*A. J. P.*, 1878, p. 182.)

³ Buchheim believes the active principle of castor oil to be *ricinoleic acid*; this has been confirmed by the experiments of Hans Meyer (*A. E. P. P.*, xxviii. 1890), who finds that both pure ricinoleic acid and the ricinoleate of glycerin are active purgatives. Ricinelaic acid, which Buchheim believed to be inactive, Meyer finds when given in fine emulsion to act as powerfully as does castor oil.

supposed by Bussy and Lecanu to belong essentially to the oil, and not to any distinct principle which it may hold in solution. According to O. Popp, castor oil differs from most other fixed oils in turning the plane of polarized light to the right. (*A. J. P.*, Aug. 1871, 354; from *A. Pharm.*, 1871.) Various substances containing coloring principles which they yield to castor oil produce beautiful fluorescence in that fluid when heated with it, such as logwood, turmeric, camwood, etc. (Charles Horner, *P. J.*, Oct. 1874, p. 282.)

By the action of concentrated sulphuric acid upon castor oil is formed a valuable product known as "*Turkey-red oil*," much used in dyeing and printing with madder and alizarine. The water-soluble portion of this Turkey-red oil is *ricinoleo-sulphuric acid*, $\text{C}_{18}\text{H}_{35}\text{O} \cdot \text{O} \cdot \text{H} \cdot \text{SO}_3$. Turkey-red oil acts as a fixing agent, imparting a superior lustre to the fibre dyed with its aid.

Castor oil which is acrid to the taste may sometimes be rendered mild by boiling it with a small proportion of water. If turbid, it should be clarified by filtration through coarse paper. On exposure to the air it is apt to become rancid, and is then unfit for use.

Uses.—Good castor oil is a mild and speedy cathartic, usually operating with little griping or uneasiness, and evacuating the contents of the bowels without much increasing the alvine secretions. Hence it is particularly applicable to *constipation* from collections of indurated fæces, and to cases in which acrid substances have been swallowed or acrid secretions have accumulated in the bowels. From its mildness it is also especially adapted to diseases attended with irritation or inflammation of the bowels, as *colic*, *diarrhœa*, *dysentery*, and *enteritis*. It is habitually resorted to in cases of *pregnant* and *puerperal women*, and is decidedly, as a rule, the best and safest cathartic for children. Infants usually require a larger relative dose than adults.

The *dose* for an infant is from one to three or four fluidrachms (3.75 to 11.25 to 15 Cc.). It is difficult of administration, from its peculiarly disagreeable taste and from its clamminess and adhesiveness to the mouth. In a few cases, the disgust which it excites is utterly unconquerable by any effort of resolution. A common method of disguising the taste is to give it floating in mint or cinnamon water, but that which we have found, upon the whole, the least offensive is to give it floating on the froth of sarsaparilla syrup mixed with carbonic acid water. Some take it in wine, or spirituous liquors, or the froth of porter, but these are often contra-indicated by their stimulant property. An excellent method is to mix it with an equal amount of glycerin and strongly aromatize with a volatile oil. It separates on standing, but can readily be reincorporated by shaking. When the stomach is unusually delicate, the oil may be made into an emulsion with mucilage or the yolk of an egg, loaf sugar, and an aromatic water. Tragacanth has been recom-

mended as producing a better emulsion than gum arabic. Tincture of opium may be added in cases of intestinal irritation. Castor oil may also be beneficially used as an enema, in the quantity of two or three fluidounces (60 or 90 Cc.), mixed with some mucilaginous liquid. It has been recommended as a local application to the breasts of nursing women, to promote the secretion of milk.

Though prone to become rancid by itself, it loses much of its susceptibility when mixed with lard, and some druggists are said to use it as a substitute for olive oil in ointments and cerates.

Dose, half a fluidounce to two fluidounces (15 to 60 Cc.).

OLEUM ROSÆ. *U. S.*, *Br.*

OIL OF ROSE

(ō'le-ŭm rō'sæ)

"A volatile oil distilled from the fresh flowers of *Rosa damascena* Mueller (Fam. *Rosaceæ*), having, when assayed by the process given below, a saponification value of not less than 10 nor more than 17. It should be kept in well-stoppered, amber-colored vials, in a cool place, protected from light. When dispensed, it should be completely liquefied by warming, if necessary, and well mixed by agitation." *U. S.* "The oil distilled from the fresh flowers of *Rosa damascena*, *Lin.*" *Br.*

Oleum Rosarum; Attar or Otto of Rose; Hulle volatile de Rose pâle, *Fr. Od.*; Essence de Rose, *Fr.*; Oleum Rosæ, *P. G.*; Rosenöl, *G.*; Essenza de rose, *It.*

This is commonly called *attar*, *otto*, or *essence of roses*. It is prepared on a large scale in Turkey in Europe, especially in the Balkan Mountains, in Egypt, Persia, Cashmere, India, and other countries of the East, but European and American commerce is at present supplied chiefly from the region constituting the southern slope of the Balkans. The Bulgarian production of rose oil for 1903 amounted to 6200 kilos, for 1904 to 5000 kilos, while for 1905 the yield was estimated at 4150 kilos (*Schim. Rep.*, Nov. 1905). The roses are gathered in May, and are distilled with the green leaves of the calyx. They are put, to the amount of 30 or 60 pounds, into a tinned copper boiler of the capacity of about 150 pounds. The heat is applied over an open fire, and a boiling temperature is continued for two hours, when the first part of the distilled fluid is returned to the boiler, and the process is continued to completion. The oil collects on the top of the water in the receiver, when it is removed from time to time as it accumulates. (*P. J.*, June, 1872, p. 1051.) In the south of France it is prepared in small quantities by distilling the petals of the rose with water. The oil concretes and

floats upon the surface of the water when it cools. The precise species of rose from which the oil is extracted is not in all instances certainly known, but it is said to be obtained from *R. damascena* in Northern India, *R. moschata* in Persia, and *R. centifolia* (*provincialis*) in the north of European Turkey. Hochstett of the Vienna University, who travelled in the region of the rose culture, and from whose paper the facts just mentioned were chiefly derived, states that the most important species cultivated in the valley of Kazanlik are *R. damascena*, *R. sempervirens*, and *R. moschata*. It is furnished in very minute proportion, not more than three drachms having been obtained by Polier in Hindostan, from 100 pounds of the petals. It is usually imported in small bottles, and is very costly.¹ Oil of rose was at one time prepared in Macedonia by crushing the petals in mills, expressing the fluid part, filtering it, and then exposing it to the sun in small glass vessels. The oil gradually collects on the surface of the liquid, and is removed. (*Ph. Cb.*, 1847, p. 783.) Landerer states that at Damascus and in other parts of Asia Minor the oil is prepared by dry distillation. The buds, being collected before sunrise, are placed in a glass retort, and the distillation is effected by a salt water bath, care being taken so to regulate the heat as not to scorch the petals. The water of the fresh roses and their oil come over together, and the latter, floating on the top, is readily separated.²

Oil of rose is nearly colorless, or presents some shade of green, yellow, or red, but, according to Polier, the color is no criterion of its value. Its odor is very powerful and diffusive. At 32.2° C. (90° F.) its sp. gr. is 0.832. Alcohol dissolves it, though not freely when cold. It is officially described as "a pale yellowish, transparent liquid, having the strong, fragrant odor of rose, and a mild, slightly sweetish taste. Specific gravity: 0.855 to 0.865 at 25° C. (77° F.). The addition of 70 percent. alcohol precipitates the paraffin hydrocarbons of the Oil, but forms a clear solution with its other constituents, the solution being slightly acid to litmus T.S. The congealing point, when determined according to the following method, should be between 18° and 22° C. (64.4° and 71.6° F.). Introduce about 10 Cc. of Oil into a test-tube of about 15 Mm. diameter; insert a thermometer in such a manner that it touches neither the bottom nor the sides of the tube. Raise the temperature of the Oil in the tube from 4° to 5° above the

¹ For an account by R. Bauer of Constantinople, of all of rose, its production, properties, adulteration, etc., see *P. J.*, Dec. 1867, 286; also *A. J. P.*, 1881, 367.

² The experiments of Schimmel are said to indicate that the oil of rose can be prepared from German-grown flowers with commercial success. It is affirmed that the product is superior to the Turkish oil in fineness and strength of aroma, and also that it differs in having a higher congealing point. German oil solidifying at 32° C., Turkish oil at 20° C. For an account of its production, see *P. J.*, Aug. 1886; also *P. J.*, 1893, 262.

saturation point by grasping it in the hand, and shake the tube gently. Allow the Oil to cool, and when the first crystals appear, note the temperature. This is regarded as the congealing point; a second test should be made for confirmation." U. S. "A pale yellow crystalline semi-solid, with the strong fragrant odor of rose and a sweet taste. Specific gravity 0.856 to 0.860 at 86° F. (30° C.). The congealing and melting points vary according to the proportion of crystalline matter, but should lie between 67° and 72° F. (19.4° and 22.2° C.)." Br. The U. S. P. (8th Rev.) regards the saponification value as of sufficient value to incorporate it as an official test, as follows:

Assay.—"Place in a weighing-bottle about 2 Cc. of the Oil of Rose, and weigh it accurately. Transfer it, with the aid of a little alcohol, to a 100 Cc. flask, and add 20 Cc. of half-normal alcoholic potassium hydroxide V.S. Connect the flask with a reflux condenser, and boil the mixture during thirty minutes on a water-bath. When cool, add 50 Cc. of distilled water and a few drops of phenolphthalein T.S., and titrate with half-normal sulphuric acid V.S. Subtract the number of Cc. of half-normal sulphuric acid V.S. required, from 20 (the 20 Cc. of half-normal alcoholic potassium hydroxide V.S. taken), multiply the difference by 27.87, and divide by the weight of the Oil to obtain the saponification value." U. S.

Oil of rose consists of two portions, one liquid, the other concrete at ordinary temperatures. These may be separated by freezing the oil and compressing it between folds of blotting paper, which absorbs the liquid oil and leaves the concrete stearopten. The liquid portion is oxygenated, while the solid portion, which is odorless when pure, consists of a mixture of several hydrocarbons, one of which melts at from 35.5° to 36.5° C., and is a paraffin of the formula $C_{15}H_{34}$. A sample of oil of rose distilled in Leipsic in 1884 yielded 28 per cent. of this stearopten, an inferior oil distilled in London gave 68 per cent., and a very good oil from the Balkans gave 9.20 per cent. The oxygenated portion consists of the two alcohols, $C_{10}H_{18}O$ and $C_{10}H_{20}O$, the former constituting 75 per cent. of the oil. This alcohol is now recognized as identical with the *geraniol* of palmarosa oil, while the compound $C_{10}H_{20}O$ corresponds to that obtained by the reduction of citronellal and has been named by Dodge, its discoverer, *citronellol*. The rhodinol of Eckart was a mixture of these two alcohols. (*Schim. Rep.*, April, 1898, 40.) While these two alcohols are mainly found in rose oil in the free state, esters of the same are also present in amounts varying from 2.5 to 3.5 per cent. (Gildemeister and Hoffmann, *Aetherische Oele*, p. 565.)

Oil of santal, other volatile oils, fixed oils, spermaceti, etc., are said to be added almost universally as adulterations. The volatile additions may be detected by their not being concrete; the fixed, by the greasy stain they leave

on paper when heated. Guibourt has offered certain tests by which he thinks the purity of the oil may be determined. (See *A. J. P.*, xxi. 318.) A. Ganswindt recommends the following tests. Agitate 1 drop of the oil with 45 Gm. of warm water, and sprinkle the solution in a moderately warm room, which will soon be filled with a rose odor, in which foreign odors may be detected without difficulty. An adulteration with a fixed oil produces a permanent grease stain upon paper, and spermaceti is left behind on the evaporation of a few drops of the oil from a watch crystal in a water bath. On mixing a few drops of pure oil of rose with an equal bulk of sulphuric acid, the rose odor is not changed, but oils used for adulteration change their odor, which becomes apparent in the rose odor. Or 5 drops of the oil are mixed in a dry test tube with 20 drops of pure concentrated sulphuric acid; when the mixture is cool it is agitated with 20 Gm. of absolute alcohol, when a nearly clear solution should be obtained, which, heated to boiling, remains clear yellowish brown on cooling. In the presence of the oils of rose geranium, palmarosa, etc., the alcoholic mixture is turbid, and on standing separates a deposit without becoming clear. (*Seifens. Ztg.*, 1881, p. 32; *A. J. P.*, May, 1881.) The oil of one of the sweet scented Pelargoniums, perhaps the *rose geranium*, is much employed in Turkey for the purpose of adulteration. According to Hanbury, who appears to have thoroughly investigated the subject, two substances especially are used in Constantinople for adulterating the oil,—one spermaceti, the other a volatile oil produced by certain grasses in the East Indies belonging to the genus *Andropogon*, large quantities of which are exported from Bombay, partly directly to Europe, partly through the Arabian Gulf, whence it reaches Constantinople. The same oil is imported into London under the name of *Turkish essence of geranium*, or *geranium oil*.¹ Tedermann (*Zeit. An. Chem.*, 1895, 5) reached the conclusion, after much experimenting, that there is no reliable chemical or physical test for the adulteration of oil of rose with geranium oil. The sense of smell, according to Conroy, furnishes the best means of determining the quality; he recommends the dissolving of one drop of oil of rose in twenty drops of alcohol, pouring the solution in one fluidounce of warm water, shaking, and comparing the odor with that of a standard sample treated in the same way. (*P. J.*, 1896, 474; see also *C. D.*, 1897, 53.) O. Helm (*A. Pharm.*, 1885) states that the test with a mixture of five parts of chloroform and twenty parts of alcohol cannot be relied upon, as no separation of crystalline scales took place in four different rose oils which were doubtless genuine. But

¹ Oil of Rhodium.—This is said to be the oil from the wood of *Convolvulus scoparius* or *Genista consariensis*. It is used to adulterate oil of rose. An oil of rhodium is sold to rat catchers as a lure for rats, which is made by mixing one part of oil of rose with twenty parts of oil of copalba.

Flückiger, on the other hand, stated that in an experience of many years it had never failed. For the other tests for oil of rose, see *N. R.*, 1883; *D. C.*, 1886. According to Bauer, the best tests of the purity of the oil are found in its congealing, in five minutes, at a temperature of 12.5° C. (54.5° F.), and its crystallizing, as a solid mass, in light, shiny plates, present everywhere throughout the liquid. These crystals are truncated semi-sided prisms, the angles of which are unequal, and which must be classed in the rhombic system. This stearoptene melted and allowed to cool, crystallizes in a manner so complete that the microscope can readily reveal the presence of foreign substances, such as spermaceti, fatty bodies, wax, and other analogous amorphous substances.

Oil of rose may be added, as a grateful perfume, to various spirituous preparations for internal use, and to cerates and ointments.

OLEUM ROSMARINI. U. S., Br.

OIL OF ROSEMARY

(ô'le-ûm rôs-mă-rî-nî)

"A volatile oil distilled from the fresh flowering tops of *Rosmarinus officinalis* Linné (Fam. *Labiata*), yielding, when assayed by the process given below, not less than 5 percent. of ester, calculated as bornyl acetate, and not less than 15 percent. of total borneol. It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "The oil distilled from the flowering tops of *Rosmarinus officinalis*, Linn." *Br.*

Oleum Rosmarini, *U. S.*; Huile volatile de Romarin, *Fr. Cod.*; Essence of Romarin, *Fr.*; Oleum Rosmarini, *P. G.*; Rosmarinöl, *G.*; Essenza di rosmarino, *It.*; Esencia de romero, *Sp.*

The fresh leaves of rosemary yield, according to Baumé, 0.26 per cent. of volatile oil, but the product is rated much higher by others. Schimmel & Co. obtained by distillation from dry French rosemary flowers 1.4 per cent. of oil.

This oil is colorless, with an odor similar to that of the plant, though less agreeable. Its sp. gr. is said to be 0.911, but reduced to 0.8886 by rectification (0.895 to 0.915, *U. S.*). Buisson gives the sp. gr. of the rectified oil at 0.896, and states that it is moderately dextrogyrate. Its reaction is neutral. It is soluble in all proportions in alcohol of 0.830, but requires for solution at 64° F. forty parts of alcohol of 0.887. (Berzelius.) It is officially described as "a colorless or pale yellow, limpid liquid, having the characteristic, pungent odor of rosemary, and a warm, somewhat camphoraceous taste. Specific gravity: 0.894 to 0.912 at 25° C. (77° F.). The Oil should be dextrogyrate, the angle of rotation being not more than +15° in a 100 Mm. tube, at a temperature of 25° C. (77° F.). The first 10 percent. ob-

tained by fractional distillation should also be dextrogyrate. Soluble in about one-half volume or more of 90 percent. alcohol; also in 2 to 10 volumes of 80 percent. alcohol." *U. S.* "Specific gravity 0.900 to 0.915. It should dissolve in twice its volume of alcohol (90 percent.), and should not rotate the plane of a polarized ray of light more than 10° to the right in a tube 100 millimetres long (absence of oil of turpentine)." *Br.* The *U. S. P.* (8th Rev.) furnishes the following assay for the borneol-content:

Assay.—"Introduce into a tared flask 10 Cc. of Oil of Rosemary, and note the exact weight; add 25 Cc. of half-normal alcoholic potassium hydroxide V.S., connect with a reflux condenser, and boil the mixture during one hour. After cooling, titrate the residual alkali with half-normal sulphuric acid V.S., using phenolphthalein T.S. as indicator. Subtract the number of cubic centimeters of half-normal sulphuric acid V.S. required from the 25 Cc. of half-normal alcoholic potassium hydroxide V.S. taken, multiply the difference of 9.734, and divide the product by the weight of the Oil of Rosemary taken to find the percentage of bornyl acetate. Wash the residual oil repeatedly with water, transfer it to a flask provided with a ground-glass tube-condenser (acetylation flask), add 10 Cc. of acetic acid anhydride and about 1 Gm. of anhydrous sodium acetate, and boil gently during one hour. Allow it to cool, wash the acetylated oil with distilled water, and afterwards with sodium hydroxide T.S., until the mixture is slightly alkaline to phenolphthalein T.S., and then dry it with the aid of fused calcium chloride, and filter. Transfer to a tared 100 Cc. flask 5 Cc. of the dry acetylated oil, note the exact weight, add 50 Cc. of half-normal alcoholic potassium hydroxide V.S., connect with a reflux condenser, and boil the mixture during one hour. After cooling, titrate the residual alkali with half-normal sulphuric acid V.S., using phenolphthalein T.S. as indicator. Subtract the number of cubic centimeters of half-normal sulphuric acid V.S. required from the 50 Cc. of half-normal alcoholic potassium hydroxide V.S. taken, multiply the difference by 7.649, and divide the product by the weight of the dry acetylated oil taken, less the above difference multiplied by 0.021; the quotient will represent the percentage of borneol in the Oil of Rosemary.

NOTE.—"The difference referred to above represents the number of cubic centimeters of half-normal alcoholic potassium hydroxide V.S. consumed by the acetylated oil." *U. S.*

Kane gives its sp. gr. at 0.897, its boiling point at 365° F. Kept in bottles imperfectly stoppered, it deposits a *stearoptene*, sometimes amounting, according to Proust, to one-tenth of the oil. Both Gladstone and Flückiger find that most of the oil consists of a hydrocarbon of the composition $C_{10}H_{16}$, boiling at 165° C. (329° F.), and Schimmel & Co. (*Schim.*

Rep., Oct. 1889) identified this hydrocarbon as *pinene*, but there is a smaller fraction boiling at from 200° to 210° C. (392° to 410° F.), which at low temperatures deposits a camphor, $C_{10}H_{18}O$, identified as borneol. Weber examined oil of rosemary in Wallach's laboratory (*Ann. Ch. Ph.*, 238, 89 to 108), and found that the fraction boiling between 176° and 182° C. contains *cineol*, $C_{10}H_{18}O$. The oil is therefore recognized at present as containing *dextrogyrate pinene*, *camphene*, *cineol*, *borneol*, and *camphor*. According to Flückiger (*A. J. P.*, 1885, 132), from 20,000 to 25,000 kilogrammes of oil of rosemary were produced in Grasse every year. It is said to be sometimes adulterated with oil of turpentine, which may be detected by mixing the suspected liquid with an equal volume of pure alcohol, the oil of rosemary is dissolved, and that of turpentine left. This oil is stimulant, but is employed chiefly as an ingredient in rubefacient liniments. For a case of fatal poisoning, see *A. J. P.*, xxiii. 286.

Dose, three to six minims (0.2 to 0.4 Cc.).

Off. Prep.—Linimentum Saponis, *U. S.*, *Br.*; Spiritus Rosmarini, *Br.*; Tinctura Lavandulæ Composita, *U. S.*, *Br.*

OLEUM SABINÆ. U. S.

OIL OF SAVIN

(ô'le-üm sâ-bî'næ)

"A volatile oil distilled from the fresh tops of Savin. It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.*

Hulle volatile (Essence) de Sabine, *Fr.*; Sadebaumöl, *G.*

According to the more recent authorities, the proportion of volatile oil obtained from savin varies as much as from 1 to 2.5 per cent. "A colorless or yellowish liquid, having a peculiar terebinthinate odor, and a pungent, bitter, and camphoraceous taste. Specific gravity: 0.903 to 0.923 at 25° C. (77° F.). The Oil is dextrogyrate, the angle of rotation varying between +40° and +60° in a 100 Mm. tube, at a temperature of 25° C. (77° F.). Soluble in about one-half volume or more of 90 percent. alcohol." *U. S.* According to Schimmel & Co. (*Schim. Rep.*, April, 1897), its specific gravity is from 0.91 to 0.925, optical rotation +45° to +60°, and it contains *pinene*, $C_{10}H_{18}$, *cadinene*, $C_{15}H_{24}$, and an alcohol, $C_{10}H_{18}O$, *sabinol*, which is present both in the free state and as acetic ester. With iodine it becomes heated, detonates, and gives off yellow and violet-red vapors. (Flaschoff.) The oil of savin is a powerful local irritant, producing, when persistently applied to the skin or the mucous membrane, violent inflammation. It has been much used for the purpose of producing criminal abortion, and in a number of such cases has caused death, the symptoms being violent abdominal pain, bloody vomiting and

purging, diminution or suppression of urine, disordered respiration, unconsciousness, convulsions, and fatal collapse. It is a powerful stimulant to the uterine system, and has been given with alleged success in *atonic amenorrhœa* and *menorrhagia*.

Externally, Pincus used it successfully, in the proportion of from five to thirty minims in a fluidounce of alcohol, for the cure of *alopecia pityroides*. He applied it by rubbing it on the head and also by means of compresses.

Dose, two to five minims (0.12 to 0.3 Cc.).

OLEUM SANTALI. U. S., Br.

OIL OF SANTAL [Oil of Sandalwood]

(ô'le-üm sän'tä-li)

"A volatile oil distilled from the wood of *Santalum album* Linné (Fam. *Santalaceæ*), yielding, when assayed by the process given below, not less than 90 percent. of alcohols, calculated as santalol. It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "The oil distilled from the wood of *Santalum album*, Linn." *Br.*

Oleum Lignî Santali; Oleum Santali Flavî; Oil of Sandal Wood; Hulle volatile (Essence) de Santal, *Fr.*; Oleum Santali, *P. G.*; Ostindisches Sandelholzöl, *Santalöl*, *G.*; Esencia de sandalo, *Sp.*

Under the name of sandal wood various drugs of diverse origin and character find their way into commerce. Of these, the wood of the *Pterocarpus santalinus* is described in this book under its official name of *Santalum Rubrum*, or *Red Saunders*. *Sandal wood bark*, which is believed by H. Stieren to be obtained from some species of *Myroxylon* or *Myrospermum*, is described as occurring in irregular, more or less smooth or unevenly corrugated pieces, of a light, whitish-cinnamon color, with dark, hard epidermis, and of an agreeable, custard-like odor, and an aromatic, slightly acrid, balsamic, bitterish taste. From it Stieren obtained over fifteen per cent. of a clear substance resembling Peruvian balsam. This bark is used for burning in churches as a substitute for frankincense, and bears no relation to sandal wood proper. (*P. J.*, xv. 680.) A sandal wood is yielded by the *Fusanus spicatus* (*S. Cygnorum*) and *F. acuminatus* (*S. acuminatum*) of Australia, whence it is shipped in large quantities to China. An oil distilled from this wood, now coming into the European market, is said to be less odorous than the official product.

Other varieties of sandal wood are collected in the Hawaiian Islands from *Santalum freycinetianum*, Gaud., and *S. pyrularium*, A. Gray; in the Feejee Islands from *S. Yasi*, Seem.; in New Caledonia from *S. austrocaledonicum*, Vieillb.; and in Queensland from *Eremophila Mitchellii*. For an account of the sandal wood oil industry of Western Australia, see *C. D.*, 1898, 708. For elaborate microscopic descriptions of the sandal woods, method

of obtaining the oil, etc., see various papers in the *P. J.*, vol. xvi.; also *Bull. Pharm.*, 1895, 55. West Australian sandal wood is derived according to Parry (*C. D.*, 1898, 11) from four species of the genus, *S. Cygnorum*, *S. lanceolatum*, *S. acuminatum* and *S. persicarium*. Venezuelan sandal wood, the source of the so-called West Indian sandal wood of commerce, is, according to E. M. Holmes (*P. J.*, 62), obtained from the *Schimmelia oleifera*, Holmes. A tree-like shrub, *Osyris tenuifolia*, Engl., belonging to the Santalaceæ, and a native of East Africa, is said to yield a wood which is very similar to that of the genuine Indian sandal wood. (*P. J.*, 60.)

The *Santalum album*, which yields the official oil, is a small tree twenty or thirty feet high, a native of the mountainous portions of India and of various islands of the Eastern Archipelago, but cultivated in India for the sake of its oil. J. L. Pigot furnished an interesting account of sandal wood cultivation accompanied by a map. (*Schimmel's Report*, 1900.)

Oil of santal is distilled in the United States, Germany, England, and India. According to the Indian Pharmacopœia the yield of oil is about 2.5 per cent. Oil of santal is habitually adulterated, castor oil and other fixed oils being added, and on the continent of Europe by the volatile oil of cedar, which is obtained by distilling the chips left in the making of lead pencils. Chapoteaut (*Bull. Soc. Chim.*, 37, p. 353) found two constituents, one of which he calls *santalol*, $C_{15}H_{26}O$, boiling at $310^{\circ} C.$, and the other *santalal*, $C_{15}H_{24}O$, boiling at $300^{\circ} C.$ Both of these are decomposed by distilling over phosphoric anhydride, the one yielding $C_{15}H_{24}$, boiling point $260^{\circ} C.$, and the other $C_{15}H_{22}$, boiling point $245^{\circ} C.$ Sesquiterpenes are also believed to be present in oil of santal. A specimen of oil of santal from South Australia, examined by Schimmel & Co. (*Schim. Rep.*, Oct. 1891), afforded a white crystalline principle, melting at 104° to $105^{\circ} C.$, which crystallized out in the oil. Parry (*P. J.*, 55, p. 118) found that a portion of the oil was saponifiable, so he assumed the presence of esters of santalol. The U. S. Pharmacopœia describes the oil of santal as "a pale yellow, somewhat thick liquid, having a peculiar, aromatic odor, and a pungent, spicy taste. Specific gravity: 0.965 to 0.975 at $25^{\circ} C.$ ($77^{\circ} F.$). The Oil is lævogyrate; its angle of rotation should be not less than -16° nor more than -20° in a 100 Mm. tube, at a temperature of $25^{\circ} C.$ ($77^{\circ} F.$) (absence of other varieties of sandalwood oil, etc.). Readily soluble in alcohol, the solution being slightly acid to blue litmus paper. It is soluble in 5 volumes of 70 percent. alcohol. The presence of chloroform may be detected in the following manner: If a small strip of filter paper folded in the form of a taper and saturated with Oil of Santal be placed in a small porcelain dish, and a clean beaker, moistened on the inner surface with distilled water, be inverted over the small dish immediately after igniting the taper,

a part of the products of combustion will be absorbed by the water; if the beaker be then rinsed with a little distilled water and the liquid filtered, the filtrate should yield no turbidity upon the addition of a few drops of silver nitrate T.S. (absence of chlorinated products)." U. S. "Somewhat viscid in consistence, pale yellow in color, having a strongly aromatic odor and a pungent and spicy taste. Specific gravity 0.975 to 0.980. It forms a clear solution with six times its volume of alcohol (70 per cent.) (absence of cedar wood oil). It rotates the plane of a ray of polarized light to the left, through an angle of not less than 16° and not more than 20° , in a tube 100 millimetres long (absence of other varieties of sandal wood oil.)" *Br.* The percentage of santalol¹ furnishes the basis for the official test, which is as follows:

Assay for Santalol. U. S. P. (8th Rev.) "Introduce 10 Cc. of Oil of Santal into a flask provided with a ground-glass tube-condenser (acetylation flask), add 10 Cc. of acetic acid anhydride and about 2 Gm. of anhydrous sodium acetate, and boil the mixture gently during one hour and a half. Allow it to cool, wash the acetylated oil with distilled water, and afterwards with sodium hydroxide T.S., until the mixture is slightly alkaline to phenolphthalein T.S., and then dry it with the aid of fused calcium chloride, and filter. Transfer to a tared 100 Cc. flask 3 Cc. of the dry acetylated oil, note the exact weight, add 50 Cc. of half-normal alcoholic potassium hydroxide V.S., connect with a reflux condenser, and boil gently during one hour. After cooling, titrate the residual alkali with half-normal sulphuric acid V.S., using phenolphthalein T.S. as indicator. Subtract the number of cubic centimeters of half-normal sulphuric acid V.S. re-

¹ According to L. Kebler (see also *Schim. Rep.*, Oct. 1895), the degree of purity of oil of sandal wood can readily be made out by estimating, by the process which follows, the percentage of santalol. This percentage probably varies in pure oils from 93 to 98. The official assay is based upon this method.

Into a flask, provided with a reflux condenser, place 20 grammes of the oil, add an equal volume of acetic anhydride (not anhydrous acetic acid) and 2 grammes of fused sodium acetate; then gently boil for about two hours. Wash the mixture first with water, then with a solution of sodium hydroxide, then with water again; finally dry the resulting oil with anhydrous sodium sulphate. Of this dried product, place from 2 to 5 grammes into a flask provided with a reflux condenser, add an excess of normal alcoholic potassium hydroxide, and boil for half an hour. Ascertain the amount of alkali consumed by titrating back the excess, with normal sulphuric acid. From the data thus obtained the amount of santalol is readily calculated by the following formula:

$$P = \frac{a \times 22.2}{s - (a \times 0.042)}$$

P, Santalol; a, number of Cc. of normal alkali consumed; and s, the amount in grammes of the acetylated oil used for saponification.

The following equations represent the reactions involved:

quired from the 50 Cc. of half-normal alcoholic potassium hydroxide V.S. taken, multiply the difference by 11.026, and divide by the weight of the dry acetylated oil taken, less the above difference multiplied by 0.021; the quotient will represent the percentage of santalol in the Oil of Santal.

NOTE.—The difference referred to above represents the number of cubic centimeters of half-normal alcoholic potassium hydroxide V.S. consumed by the acetylated oil." U. S.

The Indian Pharmacopœia gives the sp. gr. of the oil at 0.98, the British at 0.96, while in a number of specimens examined by E. M. Holmes (*P. J.*, xvi, 821) the sp. gr. varied from 0.96 to 0.99. The sp. gr. of the oil of cedar wood, according to Ince, is 0.948. A large percentage of it may be added to the oil of santal without affecting its density sufficiently to be detected. Holmes states that the presence of more than 10 per cent. of the cedar oil can be recognized through the different solubilities of the oils in alcohol. (See *P. J.*, xvi, 820.) R. A. Cripps, after a thorough examination of the oils in the London market (see *P. J.*, 1892, 461), gives this test: "Two drops of the oil added to six drops of nitric acid, sp. gr. 1.5, on a white tile, should give a yellow to bright reddish-brown coloration, without any green, indigo, or violet tint at the edges during five minutes. For complete saponification in alcoholic solution, it requires not more than 1 per cent. of potassium hydrate." (See also *A. J. P.*, 1893, 20; *Schim. Rep.*, Oct. 1893; *P. J.*, 1895, 118; *West. Drug.*, 1897, 262.) West India oil can be distinguished from the genuine oil by its deviating the plane of polarization to the right instead of to the left. (*Pharmacographia*.) In two specimens of oil of santal, sp. gr. 0.9649 and 0.9573, F. H. Alcock found strong fluorescence. (*P. J.*, 1886, 923.)

Uses.—The oil of santal is used chiefly as a perfume, but it is also a very valuable remedy in the treatment of chronic and subacute inflammations of the mucous membrane, especially in bronchitis and in gonorrhœa when the first period of severe acute inflammation has passed. It is in concentrated form a local irritant, and probably is capable of causing more or less systemic excitement, although the effects of large doses of it upon the general organism are not well known. It was first recommended by Thos. B. Henderson in gonorrhœa, who, however, is said to have used the oil of *S. myrtifolium*.

Dose, fifteen to twenty minims (0.9 to 1.3 Cc.), in emulsion, or preferably in capsule, three or four times a day.

OLEUM SASSAFRAS. U. S.

OIL OF SASSAFRAS

(*ô'le-üm säs'sä-fräs*)

"A volatile oil distilled from the root, especially the root bark, of *Sassafras variifolium*

(Fam. *Lauracæ*). It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." U. S.

Hulle volatile (Essence) de Sassafras, *Fr.*; Sassafrasöl, *G.*; Esencia de sassafras, *Sp.*

The proportion of oil yielded by the root of sassafras is variously stated at from less than 1 to somewhat more than 2 per cent. The bark of the root, directed by the U. S. Pharmacopœia, would afford a larger amount. Very large quantities of the oil were at one time distilled in Maryland and sent to Baltimore. The usual yield is said by Sharp to be one pound from three bushels of the root. From fifteen to twenty thousand pounds were sent annually, before 1861, to the Baltimore market. (*A. P. Sharp, A. J. P.*, Jan. 1863, p. 53.) At Richmond, Va., in 1871, it was being manufactured at the rate of forty gallons of pure oil per week. The root, chopped fine by machinery, has steam forced through it in a closed tub, and the oil is then distilled in the ordinary way. 800 pounds of unrectified oil are said to be obtained from 40,000 pounds of root. (*M. S. Rep.*, Aug. 26, 1871.) The oil is of a yellow color or colorless, becoming reddish by age. It has the fragrant odor of sassafras, with a warm, pungent, aromatic taste, and a neutral reaction. It is among the heaviest of the volatile oils, having the sp. gr. of 1.094, or 1.087 at 15° C. on the authority of Buignet, who states also that it is very slightly dextrogyrate. It is officially described as "a yellow or reddish-yellow liquid, having the characteristic odor of sassafras, and a warm, aromatic taste. Specific gravity: 1.065 to 1.075 at 25° C. (77° F.). The Oil is dextrogyrate, but should not deviate the ray of polarized light more than +4° in a 100 Mm. tube, at a temperature of 25° C. (77° F.). Soluble in all proportions in 90 percent. alcohol, the solution being neutral to litmus paper." U. S. The most complete investigation of sassafras oil is that made by Power and Kleber in 1896. (*Schim. Rep.*, April, 1896.) They find it to have the following composition: safrol, $C_{10}H_{10}O_2$, about 80 per cent.; pinene and phellandrene, $C_{10}H_{16}$, about 10 per cent.; dextrogyrate camphor, $C_{10}H_{16}O$, about 6.8 per cent.; eugenol, $C_{10}H_{12}O_2$, about 0.5 per cent.; a high boiling portion consisting of cadinene and residue, 3 per cent. They say that the hydrocarbon constituent of sassafras oil, to which Grimaux and Ruotte gave the name of safrene, is, as just stated, a mixture of pinene and phellandrene. Safrol, which is now official, crystallizes well in hard four- or six-sided prisms, with the odor of sassafras. It liquefies at 11° C. (51.8° F.), boils at 232° C. (449.6° F.), has a sp. gr. of 1.106, and is destitute of rotatory power. Variation in the sp. gr. of oil of sassafras may often arise through the congelation and separation of safrol, or through stratification. (Lafayette Wall and Pursel, *A. J. P.*, 1898, 340.) Flücker ascertained that safrol was one of those

remarkable bodies which are capable of existing either in a solid or in a fluid condition long after they have passed their freezing or their melting point. Chemically, it has been found to be the *methylene ether of allyl-dioxybenzene*. Safrol appears to be widely distributed in the vegetable kingdom, probably existing in the bark of the *Mespilodaphne Sassafras*, also in the *Puchury* or *Sassafras nuts*, both of Brazil, as well as in the barks of *Atherosperma moschatum* and of *Beilschmiedia obtusifolia* of Australia,¹ and in the bark of *Doryphora Sassafras* of New Caledonia. It is now commercially extracted from oil of camphor, and it probably could be obtained from the oil of various species of the genus *Cinnamomum*. (See *Safrolum*; also *P. J.*, June, 1887.)

Uses.—Oil of sassafras is chiefly used for flavoring purposes, but has physiological properties similar to those of the oil of cloves and other allied volatile oils, and may be used for similar purposes. A teaspoonful of it produced in a young man vomiting, collapse, somewhat dilated pupils, and pronounced stupor. (*Cincinnati Lancet-Clinic*, Dec. 1888.) According to the experiments of A. Heffter (*Atti Dell' XI. Congres. Med. Internaz.*, iii. 1894), safrol is slowly absorbed from the alimentary canal, and escapes through the lungs unaltered and through the kidneys oxidized into *piperonalic acid*. When taken in sufficient dose, it quickly kills by a centric paralysis of respiration, preceded by great depression of the circulation, and when taken in smaller yet toxic amount, it causes death by wide-spread fatty degeneration of the heart, liver, kidneys, etc. Its isomer, *isosafrol*, is in warm-blooded animals much less active as a poison than is safrol, and is chiefly eliminated as *piperonalic acid*.

Dose, of oil of sassafras, three to six minims (0.2 to 0.4 Cc.).

Off. Prep.—Syrupus Sarsaparillæ Compositus, *U. S.*; Trochisci Cubebe, *U. S.*

OLEUM SINAPIS VOLATILE. *U. S.*, *Br.*

VOLATILE OIL OF MUSTARD

(ō'f-ūm sj-nā'pīs vō-lāt'ī-lē)

"A volatile oil obtained from Black Mustard (freed from its fatty oil) by maceration with water and subsequent distillation, yielding, when assayed by the process given below, not less than 92 percent. of allyl iso-thiocyanate. It should be carefully kept in well-stoppered, amber-colored bottles, in a cool place, protected from light." *U. S.* "Distilled from Black Mustard seeds after maceration with water." *Br.*

Oleum Sinapis, *Br.* 1885; Oleum Sinapis Æthereum; Oil of Mustard; Huile volatile (Essence) de Moutarde, *Fr.*; Oleum Sinapis, *P. G.*; Senföl, Aetherisches Senföl, *G.*; Essenza di senape, *It.*; Esencia de mostaza negra, *Sp.*

¹ The bark described by Dymock as that of *Beilschmiedia jagifolia*, according to the researches of E. S. Hooper, contains saponin and probably is not derived from *Beilschmiedia* or any other genus of the Lauraceæ. (*P. J.*, lxxii.)

The *volatile oil of mustard* is usually obtained from seeds which have been deprived of their fixed oil by pressure. It is "a colorless or pale yellow, limpid, and strongly refractive liquid, having a very pungent and acrid odor. *Great caution should be exercised when smelling this Oil*; it should not be tasted without being highly diluted. Specific gravity: 1.013 to 1.020 at 25° C. (77° F.). Miscible with alcohol in all proportions, forming a clear solution. If to 3 Gm. of the Oil 6 Gm. of sulphuric acid be gradually added, the liquid being kept cool, the mixture, upon subsequent agitation, will evolve sulphur dioxide, but it will remain of a light yellow color, and although at first clear, it will afterwards become thick and occasionally crystalline, and the pungent odor of the Oil will disappear. If a portion of the Oil be heated in a flask connected with a well-cooled condenser, it should distil completely between 148° and 152° C. (298.4° and 305.6° F.), and both the first and the last portions of the distillate should have the same specific gravity as the original Oil (absence of alcohol, chloroform, petroleum, fatty oils, or more than traces of carbon disulphide). If a small portion of the Oil be diluted with 5 times its volume of alcohol, and a drop of ferric chloride T.S. be added, no blue or violet color should be produced (absence of phenols)." *U. S.* "Specific gravity 1.018 to 1.030. It distils between 297° F. (147.2° C.) and 306° F. (152.2° C.), and the first and last portions of the distillate should have the same specific gravity as the original Oil (absence of ethylic alcohol and petroleum)." *Br.* The *U. S. P.* (8th Rev.) furnishes the following assay process:

Assay.—"Weigh accurately about 2 Gm. of Volatile Oil of Mustard, and dilute this with sufficient alcohol to make 50 Cc. of the solution represent 1 Gm. of the Oil; of this solution, 5 Cc. are transferred to a 100 Cc. measuring flask, and 30 Cc. of tenth-normal silver nitrate V.S. and 5 Cc. of ammonia water are added. The flask is well-stoppered and set aside in a dark place for twenty-four hours. The contents of the flask are diluted with water to the 100 Cc. mark and filtered. To 50 Cc. of the filtrate, 4 Cc. of nitric acid and a few drops of ferric ammonium sulphate T.S. are added, and finally sufficient tenth-normal potassium sulphocyanate V.S. to produce a permanent red color; not more than 5.6 Cc. of the latter reagent should be required (each Cc. of tenth-normal silver nitrate V.S. consumed corresponding to 0.00492 gramme of allyl iso-thiocyanate)." *U. S.*

Will considers volatile oil of mustard to be allyl isosulphocyanate, CSNCSH₅ (allyl iso-thiocyanate), the compound radical being the same as that of oil of garlic, which is considered a sulphide of allyl. (*Chem. Gaz.*, Nos. 62 and 64.) It is the principle upon which black mustard seeds depend for their activity. Volatile oil of mustard was first produced artificially by Berthelot and S. de Luca, by treating allyl

iodide, $\text{C}_3\text{H}_5\text{I}$, with an alcoholic solution of potassium sulphocyanate. It is now extensively manufactured artificially by this method. What first forms is allyl sulphocyanate, which is not identical with, but only an isomer of, mustard oil (allyl isosulphocyanate). But if the sulphocyanate be heated to its boiling point ($161^\circ \text{C}.$) the thermometer sinks rapidly to $150^\circ \text{C}.$, because of the change into the isosulphocyanate, or mustard oil. This change also takes place spontaneously at summer temperature. A small quantity of carbon disulphide seems always to be produced at the same time.¹ Allyl iodide is procured by treating glycerin with phosphorus iodide, and differs from volatile oil of garlic (allyl sulphide) only in containing iodine instead of sulphur. (*J. P. C.*, Août, 1855, p. 124.) According to Zeller, the seeds yield from 0.33 to 0.63 per cent. of the oil. Will and Koerner in 1863 explained the occurrence of this allyl isosulphocyanate in mustard oil. It does not occur ready formed in the seeds, but is produced by the decomposition of a compound, *sinigrin* (potassium myronate), occurring there. This sinigrin, $\text{C}_{10}\text{H}_{18}\text{KNS}_2\text{O}_{10}$, is decomposed under the influence of *myrosin*, an albuminous ferment which is present, and yields as products of decomposition $\text{C}_3\text{H}_5\text{CNS}$ (allyl isosulphocyanate), HKSO_4 (acid potassium sulphate), and $\text{C}_6\text{H}_{12}\text{O}_6$ (glucose). "The aqueous solution of myrosin coagulates at $60^\circ \text{C}.$ ($140^\circ \text{F}.$), and then becomes inactive; hence mustard seed which has been heated to $100^\circ \text{C}.$ ($212^\circ \text{F}.$), or has been roasted, yields no volatile oil, nor does it yield any if powdered and introduced at once into boiling water." (*Pharmacographia*, p. 67.) As it is often adulterated with other oils, a test has been proposed consisting of concentrated sulphuric acid, 50 drops of which are to be mixed with 5 drops of the suspected oil in a small glass tube. If the oil be pure, little change of color will be produced, but if any adulterating oil be present, a red or brown color will soon appear. Rectified oil of petroleum is the only exception, as the color of this is not affected by the acid, but it would be recognized by its insolubility in sulphuric acid. (See *A. J. P.*, July, 1865, p. 285.) Ammonia converts the mustard oil into *thiosinamin*, according to the reaction

which separates in colorless rhombic crystals, melting at $70^\circ \text{C}.$, and soluble in water, alcohol, and ether. The reaction is stated by Flückiger (*Pharm. Chem.*, 2d ed., 1888, p. 20) to be quantitative. Adulteration with alcohol is readily detected by its much lower boiling point, which also enables it to be separated by distillation. It has been adulterated with considerable quan-

ties of carbon disulphide, which may be detected by distillation at a temperature not exceeding $80^\circ \text{C}.$ and mixing the distillate with sulphuric acid, when the carbon disulphide rises to the surface. Oil of mustard naturally contains about 0.56 per cent. of carbon disulphide. (*A. J. P.*, 1881, p. 572.)

White mustard seeds yield different products. When deprived of fatty oil they yield to boiling alcohol colorless crystals of *sinalbin*, an indifferent substance readily soluble in cold water, but sparingly so in cold alcohol. According to Will, it breaks up under the action of myrosin into *acrinyl sulphocyanate*, $\text{C}_7\text{H}_7\text{O.CNS}$, *sinapine sulphate*, $\text{C}_{16}\text{H}_{25}\text{NSO}_4$, and *glucose*, $\text{C}_6\text{H}_{12}\text{O}_6$. This acrinyl sulphocyanate is a nearly colorless, non-volatile oil, and the rubefacient and vesicating principle of white mustard. *Sinapine* has not yet been isolated, but it is an unstable alkaloid.

Uses.—An application of the principles developed in the foregoing paragraphs has been suggested by Lebaigue, who proposes applying to one sheet of paper a concentrated solution of *potassium myronate*, and to a second a concentrated solution of *myrosin*, and drying them. When used, the leaves are to be moistened and applied to the surface, one over the other. Volatile oil of mustard is formed by the reaction of the two principles, and a sinapism is obtained. (*J. P. C.*, Août, 1868, p. 118.) From the foregoing account of the chemical relations of mustard, it is obvious that admixture with alcohol or the acids, or the application of a boiling heat, can only have the effect of impairing its medicinal virtues, and that the best vehicle, whether for external or internal use, is water at common temperatures. The volatile oil of mustard has been employed as a substitute for the mustard plaster. For this purpose one part may be mixed with sixty parts of alcohol, and the mixture applied sprinkled not too thickly on piline or muslin, covered with waxed paper. It acts speedily and efficiently.

The oil is too pungent and irritating to be given internally.

OLEUM TEREBINTHINÆ. U. S., *Br.*

OIL OF TURPENTINE

(ō'le-ūm tēr-ē-bin'thī-næ)

"A volatile oil recently distilled from turpentine. It should be kept in well-stoppered bottles." *U. S.* "The oil distilled, usually by the aid of steam, from the oleo-resin (turpentine) obtained from *Pinus sylvestris*, *Linn.*, and other species of *Pinus*; rectified if necessary." *Br.*

Essence de Térébenthine, *Fr. Cod.*; Huile volatile de Térébenthine, *Fr.*; Oleum Terebinthinæ, *P. G.*; Terpentinöl, *G.*; Essenza di trementina, *It.*; Esencia de trementina, *Acite volatil de trementina*, *Sp.*

This oil is commonly called *spirits* (or *spirit*) of turpentine. It is prepared by distillation

¹*Allyl Bromide.*—This compound of allyl was first prepared by Wurtz in 1857 (*Ann. Ch. Ph.*, II. 91) by the reaction of allyl iodide on one and a half times its weight of bromine. It is a colorless liquid, soluble in ether, boiling at $170^\circ \text{C}.$, and having a specific gravity of 2.436. De Fleury (*A. Pharm.*, Aug. 1886) affirms that in doses of five drops, two to four times a day, in capsules, it is a valuable remedy in *hysteria*, *asthma*, and *convulsions*.

from our common turpentine, though equally afforded by other varieties. It may be distilled either with or without water, but in the latter case a much higher temperature is required, and the product is liable to be empyreumatic. To obtain it quite pure it should be redistilled from a solution of potassium hydroxide. The turpentine of *Pinus palustris* is said to yield about 17 per cent. of oil, while that from *Pinus Pinaster* affords 25 per cent., and that from *Pinus sylvestris* 32 per cent. Large quantities are distilled in North Carolina. The exportations from the United States for the year ending June 30, 1903, amounted to 16,378,787 gallons, valued at \$8,014,322, and for the year ending June 30, 1904, to 17,202,808 gallons, valued at \$9,446,155.

Pure oil of turpentine is "a thin, colorless liquid, having a characteristic odor and taste, both of which become stronger and less pleasant by age and exposure to the air. Specific gravity: 0.860 to 0.870 at 25° C. (77° F.). When Oil of Turpentine is distilled, the larger part should pass over between 155° and 162° C. (311° and 323.6° F.). Soluble in 3 times its volume of alcohol. If 5 Cc. of Oil of Turpentine be shaken with an equal volume of potassium hydroxide T.S., its color should not become darker than a light straw-yellow upon standing twenty-four hours. If 1 Cc. of the Oil be evaporated in a small dish on a water-bath, it should leave not more than a very slight residue (absence of *petroleum, paraffin oils, or rosin*). Three drops of Oil of Turpentine, placed on a sheet of clean white filter paper and exposed to the air, should evaporate entirely without leaving a permanent stain (absence of *kerosene or rosin oil*). If 5 Cc. of Oil of Turpentine be placed in a small beaker, and 20 Cc. of sulphuric acid be gradually added, with agitation, while the beaker is cooled by immersion in cold water, and the contents, after cooling and renewed agitation, be transferred to a burette, graduated in tenths, the clear layer which forms after the dark mass has settled should not measure more than 0.35 Cc. (absence of *petroleum benzin, kerosene, or similar hydrocarbons*)." U. S. "Limpid, colorless, with a strong peculiar odor, which varies in the different kinds of Oil, and a pungent and somewhat bitter taste. It is soluble in its own volume of *glacial acetic acid*. It commences to boil at about 320° F. (160° C.), and almost entirely distills below 356° F. (180° C.), little or no residue remaining." Br. As found in commerce, it always contains oxygen, but when perfectly pure it consists exclusively of carbon and hydrogen, and is composed of one or more *terpenes*. (See p. 812.) The English or American oil (prepared from *Pinus australis*) is composed of *dextro-pinene*, while the French oil (prepared from *Pinus Pinaster*) is composed of *laevo-pinene*. On the other hand, the Russian turpentine contains, in addition to *pinene*, *dipentene* (or *cinene*) and *sylvestrene*, and the Swedish turpentine contains *pinene* and *sylves-*

trene. Both the American and the French oil of turpentine boil at about 156° C. (312.8° F.). On heating oil of turpentine to about 300° C. (572° F.) in a sealed tube for several hours it is converted into a polymer called *iso-terebenthene*, $C_{20}H_{32}$, which is so oxidizable that it is converted into a viscid mass on exposure to the air for a few hours. It has, moreover, a marked odor, resembling oil of lemon, and boils at 176° to 177° C. (348.8° to 350.6° F.). On treatment with a small portion of sulphuric acid, oil of turpentine yields an optically inactive liquid, which boils at 160° C. (320° F.). This is a mixture resolvable by repeated fractional distillation into *terebene*, $C_{10}H_{16}$, boiling at 150° C. (302° F.); *cymene*, $C_{10}H_{14}$, boiling at 175° C. (347° F.); a small quantity of a camphor-like body, boiling at 200° C. (392° F.); *colophene*, $C_{20}H_{32}$, boiling at 318° C. (604.4° F.), and a mixture of semi-solid products of higher boiling point. Oil of turpentine absorbs hydrochloric acid gas, forming with it two compounds, one a red dense liquid, the other a white crystalline substance resembling camphor, and hence called *artificial camphor*. Both are *mono-hydrochlorides*, $C_{10}H_{15}.HCl$, but the latter is much more stable, and can be purified by crystallization from alcohol or ether. When turpentine oil is left in contact with concentrated hydrochloric acid a *dihydrochloride* is formed, $C_{10}H_{15}.2HCl$. This forms rhombic plates, insoluble in water, and decomposed by boiling with alcoholic potash, with formation of *terpinol* ($C_{10}H_{15}.2H_2O$). (Allen, *Com. Org. Anal.*, vol. ii. p. 51.) Nitric acid converts oil of turpentine into resin, and by long boiling into *terebic acid*, $C_7H_{10}O_4$. Mixed with water and chlorinated lime, and then distilled, the oil yields a liquid which Chautard found to be identical with chloroform (*Ibid.*, 3e sér., xxi. 88). Turpentine oil and other terpenes unite with water to form crystals of *terpin hydrate*, $C_{10}H_{15}(OH).2H_2O$, which sublimes often from turpentine oil which has long stood in contact with water and has then been heated to water bath temperature. These crystals are sometimes found in nature also. The presence of alcohol with the water and turpentine oil facilitates their formation. Thus, a mixture of 1 part of nitric acid, 1 part of alcohol, and 4 parts of turpentine oil, spread out in flat dishes, will yield within a few days crystals amounting to 20 per cent. of the oil taken. If these crystals be fused at 116° C. they will lose water, and *terpin*, $C_{10}H_{15}(OH).2$, will remain in crystalline needles, fusing at 104° C., and boiling at 258° C. If either of the hydrates just mentioned be boiled with sulphuric, phosphoric, or glacial acetic acid, *terpineol*, $C_{10}H_{17}OH$, will be formed along with hydrocarbons of the formula $C_{10}H_{16}$, such as *terpinene*, *terpinolene*, and *dipentene*. Terpineol is a thick, colorless, optically inactive liquid, with a pleasant hyacinthine odor and a bitter, feebly pungent taste. It is used extensively in perfumery. Baeyer (*Ber. d. Chem. Ges.*, 26, p. 826) has also pre-

pared the methyl ether of terpineol. Oil of turpentine may be made to yield cymene identical with that existing in the oil of cumin and with that obtained by dehydrating camphor. (See *Cumin Seed*, in PART II.) Exposed to the air the oil absorbs oxygen, becomes thicker and yellowish, and loses much of its activity, owing to the formation of resin. A small proportion of formic acid is said also to be generated. Hence the Edinburgh College directed the oil to be rectified by distilling it with about four measures of water. But the process is difficult, in consequence of the great inflammability of the vapor, and its rapid formation, which causes the liquid to boil over. In this country it is scarcely necessary, as the recent oil can be obtained at an expense less than that which would be incurred by redistillation on a small scale. Another mode of purifying the oil is to agitate it with one-eighth of alcohol, which dissolves the resinous portion. About one-fifth of the alcohol is retained by the oil, but is readily separated by agitation with water. (See *Oleum Terebinthinæ Rectificatum*.) For tests, see *Proc. A. Ph. A.*, 1893, 156.

C. T. Kingzett has shown that the atmospheric oxidation of turpentine is accompanied by the formation of a body having the formula $C_{10}H_{14}O_4$, which he regards as *camphoric peroxide*. This substance, by the action of water, is converted into hydrogen peroxide and camphoric acid. The disinfectant known as "*Sanitas*" is produced by passing air through Russian oil of turpentine in contact with warm water. Berthelot has shown that oil of turpentine has, under certain conditions, the power, while undergoing oxidation itself, of causing the oxidation of other bodies, to which it imparts a portion of the oxygen absorbed from the air. All that is necessary to give this power to the oil is that soon after distillation it should be exposed to the air, as in a bottle half filled. Solar light assists, but is not essential to, the change, which goes on even in the dark. The oil retains indefinitely the property thus acquired, but may be deprived of it by exposure to a boiling heat, or by agitation with certain other substances, as potassium pyrogallate. No other chemical or physical change can be detected in the oil. (*J. P. C.*, Mai, 1860, 351.)

In this country the oil of turpentine is frequently adulterated with petroleum distillates. The adulteration is best detected by the treatment with sulphuric acid followed by steam distillation of the oil layer remaining above the sludge acid; this treatment with acid and after-distillation to be repeated if necessary. The sulphuric acid will thus completely polymerize and resinify the essential oil, leaving the paraffin hydrocarbons unaffected in the residual oily layer. A shorter and more readily executed test with sulphuric acid, though not so complete, is now given in the official test of the U. S. Pharm. 8th Rev.

Considerable quantities of a turpentine obtained by steam distillation of the so-called

"lightwood" or resin saturated stumps and pieces of pine wood, have been offered in recent years. For an experimental study of this process and an account of the product see an article by Walker, Wiggins and Smith (*Chemical Engineer*, Dec. 1905, p. 78).

The several species of pine indigenous to California and the slopes of the Sierra Nevada appear to yield quite different products. Wenzell (*A. J. P.*, March, 1872) described, under the name of *abietene*, an oil distilled from the exudation of the *Pinus sabiniana* (*Nut Pine* or *Digger Pine*). He found it to have a sp. gr. of 0.694, and to boil at 101° C. (213.8° F.). Sadtler (*A. J. P.*, April, 1879, p. 176) examined an oil of turpentine from California said to have been obtained from the *Pinus ponderosa* (*Heavy Pine*), and found it to agree substantially with Wenzell's *abietene*. It had a sp. gr. at 16.5° C. (62° F.) of 0.6974, boiled at 101° C. (213.8° F.), and was slightly *lævogyrate*. It gave negative results when treated with hydrochloric acid for the formation of a hydrochloride, did not form a hydrate, and was not acted upon by sulphuric acid or by nitrosyl chloride. These anomalous results were at once explained by the publication of a study of the *abietene* which had been made by Thorpe, who showed (*A. J. P.*, 1879, p. 293) that this exudation of the California pine is almost pure *heptane*, C_7H_{14} , one of the chief constituents of American petroleum. His results were also confirmed by Schorlemmer, who established the identity of the pine *heptane* with that from petroleum naphtha.

Uses.—Oil of turpentine is stimulant, diuretic, occasionally diaphoretic, anthelmintic, in large doses cathartic, and externally rubefacient. Swallowed in moderate quantities it produces a sense of warmth in the stomach, accelerates the circulation, and increases the heat of the skin, without especially affecting the functions of the brain. In small doses frequently repeated it stimulates the kidneys, augmenting the secretion of urine, and often producing, especially if long continued, painful irritation of the urinary passages, amounting sometimes to violent strangury. At the same time it imparts the odor of violets to the urine, and this effect is also produced by its external application, or even by breathing the air of an apartment impregnated with its vapors. In large doses it occasions slight vertigo, or a sense of fulness in the head, sometimes amounting to intoxication, attended frequently with nausea, and succeeded generally, though not always, by speedy and brisk catharsis. When this effect is experienced, the oil is carried out of the bowels, and, no time being allowed for its absorption, is less prone to irritate the kidneys and bladder than if given in small and repeated doses. In some constitutions it produces, even when taken internally, an erythematous eruption on the skin. Persons who inhale its vapor are liable to strangury and even bloody urine. Hæmaturia is sometimes caused in seamen on

board vessels loaded with turpentine. A woman was found dead after having swallowed a large quantity of the oil, probably about six ounces. (*Am. J. M. S.*, Oct. 1858.)

The oil is employed in numerous diseases. As a stimulant it sometimes proves serviceable in *low forms of fever*. We have found it extremely useful in the advanced stage of *typhoid* or *enteric fever*, and especially in cases in which the tongue has partially or completely thrown off its fur in flakes, and afterwards become dry, with a surface destitute of its ordinary papillary appearance, and often contracted and fissured. The remedy has in our hands proved almost uniformly successful under these circumstances. With small doses of the oil frequently repeated, the tongue becomes moist and again coated, the tympanitic state of the bowels disappears, and the patient goes on to recovery as in a favorable case of fever. Its efficiency, however, in typhoid fever is ascribable not so much to its stimulant properties as to an alterative influence upon the ulcerated surface of the bowels characteristic of that disease, and the remedy is often of great service when during the convalescence from typhoid fever diarrhœa due to slow healing of the ulcers occurs. In *chronic rheumatism*, particularly *sciatica* and *lumbago*, the oil has often been given with great benefit. It has also been much extolled as a remedy in some forms of *puerperal fever*, in *neuralgia*, in *passive hemorrhages*, particularly from the bowels, in *chronic dysentery* and *diarrhœa*, in obstinate *gleets* and *leucorrhœa*, in *retention* and *incontinence of urine* from debility, in *chronic nephritic* and *calculous affections*, and in various conditions of *whooping cough*. In certain cases of *dysentery*, whether acute or chronic, when the tongue is quite dry, and smooth as if from defect of the papillary structure, no remedy has proved so efficient in our hands as oil of turpentine. We have seen it also very beneficial in *hæmoptysis*. As a vermifuge it is highly esteemed, especially in cases of *tænia*. It appears to destroy or debilitate the worm, which, losing its hold upon the bowels, is then easily discharged. In cases of *worms in the stomach* this oil is very useful, and in *amenorrhœa* from torpor of the uterine vessels it is occasionally of service. (*A. J. P.*, March, 1869.)

The dose for ordinary purposes is from five to thirty minims (0.3 to 1.8 Cc.), repeated every hour or two in acute, and three or four times a day in chronic diseases. In rheumatism it is recommended by some in the dose of a fluidrachm (3.75 Cc.) every four hours. As a remedy for tape worm the dose is from one-half to one fluidounce (15 to 30 Cc.), followed by castor oil in half an hour. It has also proved successful in *tænia* in the dose of thirty minims (1.8 Cc.), twice a day, continued for a considerable time. In ordinary cases of worms, the usual dose may be given. It may be administered on sugar, or in emulsion with

gum arabic, loaf sugar, and cinnamon, or mint water. As its taste is very disagreeable to some persons, it may be administered in capsules.¹

In the form of enema, the oil is highly useful in cases of *ascarides*, of *obstinate constipation*, and especially of *tympanites*. From half a fluidounce to two fluidounces (15 to 60 Cc.) may be administered in some mucilaginous fluid.

Externally applied, oil of turpentine irritates and speedily inflames the skin, and is one of the most efficacious rubefacients; it is used in *rheumatic affections*, and in various internal inflammations. When only a slight impression is desired, it may be diluted with olive oil, but in some constitutions, even in this state, it produces such violent inflammation of the skin, with extensive eruptions, as to render its external use in any shape improper. Applied to recent *burns*, it is thought by some to be highly useful in allaying the burning pain and promoting a disposition to heal. For this purpose, however, it is usually mixed with rosin cerate (*basilicon ointment*), so as to form a liniment capable of being spread upon linen rags. (See *Linimentum Terebinthinæ*.)² Beullard has found it useful in *eczema*, applied directly to the affected part. It causes immediately severe pain and much swelling, and in a few minutes must be removed, and followed by cooling and demulcent measures. A modification of the disease is thus produced, which renders ordinary applications successful that had been previously useless. (*Ann. Thér.*, 1865, p. 138.) It is thought by von Erlach and Lucke of Berne, to be peculiarly efficacious in *parasitic affections* of the scalp, by destroying the parasites and preventing the development of the spores. (*Am. J. M. S.*, July, 1869, p. 248.)

Oil of turpentine has been recommended, in the form of bath, in affections in which its constitutional impression is desired. For this purpose, T. Smith of Cheltenham, England, employs from five to ten fluidounces of the oil, with half a fluidounce of oil of rosemary, and two pounds of sodium carbonate, in each bath. The breath becomes strongly impregnated with the terebinthinate odor. (*Braithwaite's Retrospect*, xxi. 355.) Applied in vapor, the oil is said to be a very speedy cure for the *itch*.

¹ It has been objected to the form of capsule, that, in consequence of the breaking of its coating, the oil may come undiluted in contact with the mucous membrane, and thus produce undue irritation. Lacambre gives the following process for making a pill of the oil. Take of oil of turpentine 8 grammes, white wax 20 grammes, powdered sugar 9 grammes, oil of lemon 2 drops. Melt the wax in the oil of turpentine, pour into a mortar, allow to cool, then add the sugar and oil of lemon, and form a mass to be divided into pills of 25 centigrammes (3 or 4 gr.) each. Roll them in powdered starch, and keep in a well-stoppered bottle. (*J. P. C.*, Sept. 1873, p. 223.)

² The following is the formula adopted by the Philadelphia College of Pharmacy for the rubefacient liniment known as *British Oil*. Oil of Turpentine, Linseed Oil, of each 8 fl. oz., Oil of Amber, Oil of Juniper, of each 4 fl. oz., Barbados Petroleum 3 fl. oz., Crude American Petroleum 1 fl. oz.

The bed and night clothes are sprinkled with thirteen fluidrachms of the oil, and on awaking in the morning the patient is usually cured. (*Am. J. M. S.*, July, 1857, p. 232.) Baths of the vapor of turpentine are stated to be very beneficial in chronic rheumatism. They are said to be borne well, for twenty-five minutes, at a temperature of from 60° to 71.1° C. (140° to 160° F.). (*A. G. M.*, 4e sér., xxviii. 80.) Inhalation of the vapor has been recommended by Skoda in *gangrene of the lungs*. For internal use the rectified oil should be used. (See *Oleum Terebinthinæ Rectificatum*.)

Dose, five minims to one fluidrachm (0.3 to 3.75 Cc.).

OLEUM TEREBINTHINÆ RECTIFICATUM. U. S.

RECTIFIED OIL OF TURPENTINE

(ô'le-ûm tēr-ē-bîn'thī-næ rēc-tī-fī-cā'tûm)

Essence de Térébenthine purifiée, *Fr.*; Oleum Terebinthinæ Rectificatum, *P. G.*; Gereinigtes Terpenöl, *G.*

"Oil of Turpentine, a convenient quantity; Solution of Sodium Hydroxide, a sufficient quantity. Shake the Oil of Turpentine thoroughly with an equal volume of Solution of Sodium Hydroxide, and introduce the mixture into a copper still connected with a well-cooled condenser. Recover about *three-fourths* of the Oil by distillation, separate the clear Oil from the water, and filter. Keep the product in well-stoppered, amber-colored bottles, in a cool place. Rectified Oil of Turpentine should always be dispensed when oil of turpentine is required for internal use." *U. S.*

When oil of turpentine is distilled in contact with sodium hydroxide solution, the distillate comes over purified and freed from the products which give the commercial oil the disagreeable odor and taste which are inseparable by ordinary distillation; hence this rectified oil is much preferable for internal administration. In the *U. S. P.* (8th Rev.) solution of sodium hydroxide was preferred to lime water, which was used in the *U. S. P.* 1890 to furnish an alkali to combine with resinous substances in commercial oil of turpentine. It has in other respects the same properties as Oleum Terebinthinæ. "A thin, colorless liquid, which should conform to the properties and tests given under *Oleum Terebinthinæ*. Specific gravity: 0.860 to 0.865 at 25° C. (77° F.). If about 10 Cc. of the Oil be evaporated in a dish on a water-bath, no weighable residue should be left." *U. S.*

Dose, five minims to one fluidrachm (0.3 to 3.75 Cc.).

OLEUM THEOBROMATIS. U. S., Br.

OIL OF THEOBROMA [Butter of Cacao, Cacao Butter]

(ô'le-ûm thê-q-brô'mā-tis)

"A fixed oil expressed from the roasted seeds of *Theobroma Cacao* Linné (Fam. *Sterculiaceæ*)." *U. S.* "A concrete oil obtained by pressing the warm crushed seeds of *Theobroma Cacao*, Linn." *Br.*

Oleum Theobromæ, *U. S.* 1880; Cocoa butter (improperly); Beurre de Cacao, *Fr. Ood.*; Oleum concretum e semine Theobromæ Cacao, *Fr.*; Oleum Cacao, *P. G.*; Kakaobutter, *G.*; Manteca de coco, Aceite de coco, *Sp.*

Theobroma Cacao, Linn., *Sp. Plant.* 1100; Hayne, *Darstel. und Beschreib.*, ix. 35; *B. & T.* 38.—This is a handsome tree, from twelve to twenty feet in height, growing in Mexico, the West Indies, and South America. It is largely cultivated in all tropical countries, particularly in Guayaquil, Venezuela, Mexico, Trinidad, and the Philippines. The fruit is an oblong-ovate capsule or berry, six or eight inches in length, with a thick, coriaceous, somewhat ligneous rind, enclosing a whitish pulp, in which numerous seeds are embedded. These are ovate, somewhat compressed, about as large as an almond, and consist of an exterior thin shell and a brown oily kernel. Separated from the matter in which they are enveloped, they constitute the *cacao*, or *chocolate nuts*, of commerce. The cacao tree is usually cultivated in large estates, where it is grown in the shade of the banana or other large plant, and develops its pods from the stem continually, so that the harvest goes on all the time, although the product is greater in the spring and in the autumn. The pods are cut off, opened, and the beans contained in the glutinous sweet acid pulp are allowed to ferment, during which process the outer integument comes off easily and falls. The beans are finally carefully dried, commonly in the sun, sometimes by means of a steam drying shed. If the sweating process is carried too far, or the beans during drying are wetted by rain, they blacken and are much lowered in value. These blackened beans are sometimes artificially whitened. Cacao beans have a slightly aromatic, bitterish, oily taste, and, when bruised or heated, an agreeable odor. (See *Am. Drug.*, 1897, 311; also *Ph. Ztg.*, 1900, 756.)

The average of a number of analyses of raw nuts gave H. Weigmann (*König's Nahrungs- und Genussmittel*, 3d ed., vol. i. 1019) water, 7.93 per cent.; nitrogenous matter, 14.19 per cent.; theobromine, 1.49 per cent.; fatty matter (cacao butter), 45.57 per cent.; starch and other carbohydrates, 22.92 per cent.; crude fibre, 4.78 per cent.; pure ash, 3.99 per cent.; sand, 0.62 per cent. The coloring matter is probably the result of chemical change, as the fresh seeds are white. Theobromine has been found also in the shells in the proportion of

about 1 per cent. (*A. J. P.*, 1862, 509.) The latter impart to boiling water a taste analogous to that of chocolate, but weaker, and are used for making a table beverage.

Theobromine was discovered by Woskresensky, who obtained it by the following method. The kernels are exhausted with water by means of the water bath; the solution is strained through linen, precipitated by lead acetate, and filtered; the filtered liquor is freed from lead by hydrogen sulphide, and evaporated; the brown residue is treated with boiling alcohol, and the liquor filtered while hot. Upon cooling, the theobromine is deposited in the form of a reddish-white powder, which is rendered colorless by repeated crystallization. Keller obtained it still purer by heating the powder between two watch glasses, by which a brilliant white sublimate was obtained. According to O. Donker and C. Treumann, theobromine is contained not only in the cotyledons but also in the shells of the cacao seeds. Four kilos of the latter yielded 13.5 Gm. of pure theobromine. (*A. Pharm.*, July, 1878.) Theobromine is a crystallizable alkaloid, capable of forming salts with the acids, very bitter, volatilizable without change, freely soluble in hot alcohol, sparingly so in hot water, and is very closely related to caffeine, this latter being the methyl derivative of theobromine. Its formula is $C_7H_8N_4O_2$. It has been converted into caffeine by Strecker, and afterwards E. Fischer (*Ber. d. Chem. Ges.*, 1882, p. 453) obtained theobromine from xanthine, $C_5H_4N_4O_2$, which is easily obtained from the guanine of guano, $C_5H_5N_5O$, by the action of nitrous acid. (See *Theobromine*, PART II.) For Emminger's method of determining theobromine in cacao, see *P. J.*, 1896, 289.

Chocolate is differently prepared in different countries. In Great Britain and the United States it is usually made, when pure, exclusively of the kernel of the cacao or chocolate nuts, which are first roasted, then deprived of their shells, and lastly reduced, by grinding between heated stones, to a paste, which is moulded into oblong cakes. Not unfrequently rice flour or other farinaceous substance, with butter or lard, is added, but these must be considered as adulterations. On the continent of Europe, sugar is generally incorporated with the paste, and spices, especially cinnamon, are often added. Vanilla is a favorite addition in America, France, and Spain. Cacao, wrongly called *cocoa*, is often sold in powder, which is sometimes mingled with other ingredients, such as ground rice, barley flour, sugar, etc. Chocolate is prepared for use by reducing it to powder and boiling it in milk, water, or a mixture of these fluids. In this state it is much employed as a drink at breakfast and tea, and serves as a substitute for coffee in dyspepsia. It is also a good article of diet for convalescents, and may sometimes be given advantageously as a mild nutritive drink in acute diseases. Hagenbuch examined several

commercial brands of chocolate, and found that the amount of fat or cacao butter present varied from 12 to 45.8 per cent. (*A. J. P.*, 1885, p. 276.) From this it would seem that manufacturers do not uniformly extract the fat from commercial chocolate.

Oil of Theobroma. Cacao Butter.—This is the fixed oil of the chocolate nut. It is extracted either by expression, decoction, or the action of a solvent. Soubeiran recommends that the seeds, previously ground, be mixed with one-tenth of their weight of water and then pressed between hot plates of tinned iron. It is advisable that the heat should not exceed that of boiling water, and even a lower heat will answer. When the method of decoction is used, the cacao should be slightly roasted before boiling. As a solvent, carbon disulphide has been found to answer well, as recommended in the preparation of the expressed oil of nutmeg. (See *Oleum Myristicæ*.) Upon the whole, the method of expression is perhaps preferable. The presence of water in the ground seeds is said greatly to facilitate the process. The expressed oil, now made largely in Philadelphia, occurs in the shape of oblong cakes, like those of chocolate, weighing about half a pound each. It is "a yellowish-white solid, having a faint, agreeable odor, and a bland, chocolate-like taste. Specific gravity: 0.970 to 0.976 at 25° C. (77° F.). Oil of Theobroma should be brittle at temperatures below 15° C. (59° F.), and should melt at 30° to 35° C. (86° to 95° F.) to a clear liquid. It is readily soluble in ether, chloroform, or benzene; also soluble in 100 parts of cold absolute alcohol, and in 20 parts of boiling absolute alcohol; the solutions should be neutral to test paper. If 1 Gm. of Oil of Theobroma be dissolved in 3 Cc. of ether in a test-tube at a temperature of 17° C. (62.6° F.), and the tube frequently plunged into water at 0° C. (32° F.), the liquid should not become turbid nor deposit white flakes in less than three minutes; and if the mixture after congealing be again brought to 15° C. (59° F.), it should gradually form a perfectly clear liquid (absence of *wax, stearin, tallow*, etc.). Oil of Theobroma, saponified by alcoholic potassium hydroxide T.S., should show a saponification value of 188 to 195 (see PART III, Test No. 99). If 0.8 Gm. of Oil of Theobroma be dissolved in 10 Cc. of chloroform in a 250 Cc. bottle or flask, and 25 Cc. of a mixture of equal volumes of alcoholic iodine T.S. and alcoholic mercuric chloride T.S. added, and if, after standing for four hours, protected from light, 20 Cc. of potassium iodide T.S. be added and the mixture diluted with 50 Cc. of water, on titrating the excess of iodine with tenth-normal sodium thiosulphate V.S. an iodine value of not less than 33 nor more than 38 should be obtained (see PART III, Test No. 51)." *U. S.* "A yellowish-white solid, breaking with a smooth fracture; odor resembling that of *cocoa*; taste bland and agreeable; free from rancidity. It softens at 80° F. (26.6° C.) and

melts at temperatures between 88° and 93° F. (31.1° and 33.9° C.). If 1 gramme be dissolved in 3 cubic centimetres of *ether*, in a test-tube, at 62° or 63° F. (or 17° C.), and the tube be placed in water at 32° F. (0° C.), the liquid should neither become turbid nor deposit a granular mass in less than three minutes; and if the mixture after congealing be exposed to a temperature of 60° F. (15.5° C.) it should gradually afford a clear solution (absence of other fats).” *Br. Cacao butter* consists chiefly of the glycerides of stearic, palmitic, and lauric acids, and, further, of small quantities of the glycerides of arachidic, linolic, formic, acetic, and butyric acids. The percentage of stearic acid obtainable is from 39.9 to 40.6. Kingzett believes it to contain in addition a peculiar acid which he calls *theobromic*, and to which he gives the formula $C_{64}H_{128}O_{32}$, but his results have not been confirmed by subsequent investigators. From its large proportion of stearin, it is one of the best fats for the preparation of stearic acid. It is said to be frequently adulterated with animal fats, which, according to E. Lamhofer, may be detected by attention to the fact that pure cacao butter dissolves entirely in ether or petroleum benzin, separating out in minute granular crystals when immersed in water of 0° C. (32° F.), the liquid portion remaining transparent for 30 or 40 minutes, when the whole solidifies. After solidification, if the oil be kept at a temperature of about 14.4° C. (58° F.), it will redissolve without turbidity. (*A. J. P.*, 1877, p. 238.) G. Ramsperger concludes, as the result of much experimentation, that ether affords the best test of purity. Dissolving the suspected cacao butter in 2 parts of ether, if it become turbid after standing or form on spontaneous evaporation little crystals or grains not soluble in 2 parts of ether at common temperature, it is impure and should be rejected.

Butter of cacao is used as an ingredient in cosmetic ointments, and in pharmacy for coating pills, and preparing suppositories. For the last purpose it is well adapted by its consistence and blandness, and is now largely consumed. It was, indeed on this account chiefly that it was introduced into the U. S. Pharmacopœia of 1860.¹ F. Bringham prepared a *lip salve* by melting together 28 ounces of cacao butter, 4 ounces of yellow wax, and a drachm, each, of balsam of Peru and benzoic acid, straining, adding perfuming oils, as those of rose, bergamot, and bitter almond, in suffi-

cient quantity, and finally, when nearly cool, an ounce of glycerin. (*A. J. P.*, July, 1867, p. 348.)

Owing to its great insolubility, pure theobromine acts very slowly and uncertainly upon the animal organism, but its soluble salts (notably the *salicylate of sodium and theobromine*²) are active diuretics, acting desirably upon the secreting tissue and have been much used in various dropsies. They are said not to irritate the kidneys, and have been highly commended not only in *chronic* but even in *acute Bright's disease*. Their action upon the circulation has not been determined; what evidence we have, however, indicates that large therapeutic doses have no effect upon the blood pressure, though it may increase the rapidity of the pulse. The toxic dose lowers the arterial pressure, according to Bock, by a direct action upon the cardiac muscle. Usually their action is not accompanied by any systemic disturbances, but headache, irregularity of the pulse, vomiting, and diarrhœa have been noticed in various cases, and, according to W. Schmieden, hæmaturia.

OLEUM THYMI. U. S.

OIL OF THYME

(ô'le-ûm thý'mî)

“A volatile oil distilled from the leaves and flowering tops of *Thymus vulgaris* Linné (Fam. *Labiata*), and containing, when assayed by the process given below, not less than 20 percent, by volume, of phenols. It should be kept in well-stoppered, amber-colored bottles, in a cool place, protected from light.” *U. S.*

Huile volatile de Thym, *Fr. Cod.*; Essence de Thym, *Fr.*; Oleum Thymi, *P. G.*; Thymlanöl, *G.*; Esencia de tomillo, *Sp.*

In the south of France thyme grows wild in great abundance, and is largely collected for distillation. The oil is taken from France to England, and thence reaches this country under the name of *oil of origanum*, having, probably from its greater cheapness, been substituted for the genuine oil. For all the purposes for which oil of origanum was used, that of thyme is not less useful, and is more agreeable.

Thymus vulgaris is a very common plant, indigenous to Southern Europe, and cultivated in our gardens. It possesses a subcampanulate two-lipped calyx, villous in the throat; corolla limb two-lipped, the upper erect and

¹ *Mafurra Tallow*.—This is a fat obtained from the fruit of a tree, *Trichilia emetica*, Vahl., Fam. *Meliaceæ*, growing in Mozambique and the islands of Madagascar and Bourbon, and bears a close resemblance in properties to cacao butter. The kernel of the fruit is described as of the size of the cacao bean, having the same characteristic odor when bruised, and a bitter taste. The fatty matter is extracted by boiling the kernels in water. It is of a firm, solid consistence, less fusible than tallow, of a yellowish color and of the odor of cacao butter. It agrees, moreover, with that substance in containing olein and palmitin, and yields palmitic acid largely when saponified. (*A. J. P.*, xxviii, 163.)

² A mixture of a compound of sodium theobromine and sodium salicylate has been introduced under the trade name of *diuretin*. It is a white powder, soluble in less than half its weight of water when warmed. It should contain 49.7 per cent. of theobromine and 38.1 per cent. of salicylic acid.

emarginate, the lower spreading, three-cleft. It is a low under-shrub, procumbent at the base, with ovate-linear, revolute leaves, the flowers in a whorled spike. The herbaceous portion, which should be gathered when the plant is in flower, has a peculiar, strong, aromatic, agreeable odor, not lost by drying, and a pungent, aromatic, camphoraceous taste. Its active constituent is the volatile oil, which is obtained separate by distillation with water.

The oil, as prepared in the south of France, is, after one distillation, of a reddish-brown color, and called the *red oil*, but when again distilled is colorless, and in this condition is distinguished as the *white oil*. Oil of thyme is officially described as "a colorless liquid, having a strong odor of thyme, and an aromatic, pungent, afterwards cooling taste. Specific gravity: 0.900 to 0.930 at 25° C. (77° F.). It is slightly lavogyrate; not more than -3° in a 100 Mm. tube, at a temperature of 25° C. (77° F.). Oil of Thyme is soluble in half its volume of alcohol, also in 1 to 2 volumes of 80 percent. alcohol. With a drop of ferric chloride T.S. it yields a greenish-brown color, which changes to reddish. If 1 Cc. of Oil of Thyme be shaken with 10 Cc. of hot water, and, after cooling, the liquid be passed through a wet filter, the filtrate should not assume, with a drop of ferric chloride T.S., a bluish or violet color (absence of *official phenol*)." *U. S.* The *U. S. P.* (8th Rev.) introduced an assay based on the phenols content as follows:

Assay.—"Introduce 20 Cc. of solution of sodium hydroxide (1 in 20) into a burette of 50 Cc. capacity (graduated in tenths). Add 10 Cc. of the Oil to be assayed, stopper the burette with a well-fitting cork, shake the mixture thoroughly, and set aside for twelve to twenty-four hours. Drops of Oil adhering to the side of the burette should be loosened by tapping and rotating the burette. After the alkaline solution has become clear, the volume of non-phenol oil remaining (which should measure not more than 8 Cc.) is noted and subtracted from the 10 Cc. of the Oil originally taken. The difference, multiplied by 10, indicates the percentage of phenols in the Oil." *U. S.* According to Zeller, one pound of the fresh herb yields 45.7 grains of the oil, of the dried herb 38 grains. The oil, as found in commerce, is of a reddish-brown color, and of an odor recalling that of thyme, but less agreeable. Its sp. gr. is stated at 0.905, but probably varies, as the oil is a complex body. The more volatile portion, that coming over below 180° C. (356° F.) in distillation, is a mixture of *cymene*, $C_{10}H_{14}$, boiling at 175° C. (347° F.), and *pinene*, $C_{10}H_{16}$, boiling at 161° C. (321.8° F.). The less volatile and most valuable portion is chiefly *thymol*, $C_{10}H_{14}O$, a white crystalline solid, melting at 50° C. (122° F.), and possessing a pungent taste. (See *Thymol*.) *Carvacrol* is also present, at times replacing part or all of the thymol, and in addition *linalool* and *bormyl acetate* have been found in

small amount. (See *Proc. A. Ph. A.*, 1897, 637.) The Oil is commonly adulterated with the oil of turpentine, the *white oils* being especially impure. The presence of oil of turpentine according to Duyk (*J. P. A.*, 1899, 41) is due to the fact that the French peasants place in the body of the still as a foundation for the herbs a layer of pine and fir branches. According to both Duyk and Kebler (*J. P. C.*, 5, 13, 593, 1886) the genuine oil of thyme should contain from 20 to 30 per cent. of phenol bodies and as a test for the purity of the oil of thyme based upon the amount of phenol bodies that should be in it, Kebler proposes the following: Partially fill a 100 Cc. nitrometer with a 5 per cent. solution of sodium hydroxide, then introduce 10 Cc. of the oil to be examined, shaking well for five minutes, and finally setting aside for twenty-four hours. The drops adhering to the nitrometer can be, in part, loosened by rotating or tapping the nitrometer. When the solution has become clear the non-phenol oil can readily be read off and the percentage calculated. See the official assay. The annual production of oil of thyme at Grasse, according to Flückiger (*A. J. P.*, 1885, 132), amounted to 40,000 kilogrammes. According to Camperdon, in doses of from three to fifteen grains (0.2 to 1.0 Gm.), oil of thyme causes mental excitement, and is a valuable diffusible stimulant in *collapse*. It is certainly an antiseptic. (See *Thymol*.)

Dose, three to five minims (0.2 to 0.3 Cc.).

OLEUM TIGLII. *U. S.* (Br.)

CROTON OIL

(ō'le-ūm tig'li-I)

"A fixed oil expressed from the seeds of *Croton Tiglium* Linné (Fam. *Euphorbiaceæ*). It should be kept in small, well-stoppered bottles, and should be handled with caution." *U. S.* "The oil expressed from the seeds of *Croton Tiglium*, Linn." *Br.*

Oleum Crotonis, *Br.*; Huile de Croton Tiglium, *Fr. Cod.*; Huile de Graines de Tilly, *Fr.*; Oleum Crotonis, *P. G.*; Krotónöl, *G.*; Olio di crofontiglio, *It.*; Aceite de croton tiglio, Aceite de grano tiglio, *Sp.*

Croton Tiglium, Willd., *Sp. Plant.* iv. 543; *B. & T.* 239.—This species of Croton is a small tree or shrub, with a few spreading branches, bearing alternate petiolate leaves, which are ovate, acuminate, serrate, smooth, of a dark-green color on the upper surface, paler beneath, and furnished with two glands at the base. The flowers are in erect terminal racemes, scarcely as long as the leaf,—the lower being female, the upper male, with straw-colored petals. The fruit is a smooth capsule, about the size of a filbert, with three cells, each containing a single seed.

The tree is a native of Hindostan, Ceylon, the Moluccas, and other parts of India. It is

pervaded by an acrid purgative principle, probably analogous to that found in other plants belonging to the family of Euphorbiaceæ. Rumphius says that the root is employed in Amboyna, in the dose of a few grains, as a drastic purge in dropsy, and, according to the same author, the leaves are so acrid that when chewed and swallowed they excite inflammation in the lips, mouth, and throat, and along the whole course of the alimentary canal. The wood is said in small doses to be diaphoretic, in larger, purgative and emetic. But the seeds are the most active part. These have been long used in India as a powerful purgative, and were employed so early as 1630 in Europe, under the names of *grana Molucca* and *grana tiglia*. But in consequence of their violent effects they fell into neglect, and had ceased to be ranked among medicines, when, at a comparatively recent period, attention was again called to them by the writings of some English physicians in India. They are now imported for their oil, which is the only official product of the plant. It is probable that most if not all of the Crotons are purgatives. The oil of the Mexican *Croton morifolius* is said to be mildly purgative in doses of two or three minims (0.12 to 0.2 Cc.). In India, under the name of *Kowli seeds* (*Kuli seeds*),¹ are used certain beans, which have been referred by authorities to the *Croton oblongifolius*, Roxb., and also to the *C. persimilis*, Müll.-Arg. (See *Ph. Rev.*, Oct. 1896.)

These seeds are rather larger than a grain of coffee, oblong, rounded at the extremities, with two faces, the external considerably more convex than the internal, separated from each other by longitudinal ridges, and each divided by a similar longitudinal ridge, so that the whole seed presents an irregular quadrangular figure. Sometimes, as in the coffee grain, their internal surface is flat, with a longitudinal groove, owing to the presence of only two seeds in the capsule, the groove being produced by the central column or axis. The shell is covered with a soft, yellowish-brown epidermis, beneath which the surface is black and smooth, and, as the epidermis is often partially removed by friction during their carriage, the seeds as they come to us are frequently mottled, and sometimes nearly black. The kernel or nucleus is yellowish brown, and abounds in oil. In India the seeds are prepared for use by submitting them to slight torrefaction, by which the shell is rendered more easily separable. In the dose of one or two grains (0.065 or 0.13 Gm.) the kernel purges severely.

¹ Kowli seeds reach a length of two and one-tenth Cm., a breadth of one and two-tenths Cm., a thickness of eight-tenths Cm., ovate, having pointed ends with a marked caruncle. The outer side shows the grayish-brown crusty seed coat with irregular rough longitudinal stripes; the cross-section shows a large endosperm, in the middle the embryo of considerable size with flat cotyledons. Besides the fatty oil and protoplasm, the cells of the endosperm show longitudinally very large aleurone grains, which contain a considerable number of small globoids and badly formed crystalloids.

The oil is obtained by expression from the seeds, previously deprived of the shell. It may also be separated by decoction in water, or by the action of ether, or carbon disulphide, which dissolves the oil and leaves it behind when evaporated.² Guibourt recommends, after the first expression, to digest the residue with alcohol at a temperature of 48.3° to 60° C. (120° to 140° F.), and then submit it to a new expression. The alcohol is to be separated by distillation from the oil, which is then to be mixed with the first product. Great care must be used, during this distillation, to prevent blistering the unprotected skin of the operator.

Properties.—The seeds consist of 64 per cent. of kernel and 36 of envelope. From the seeds imported into England, about 22 per cent. of oil is obtained by simple expression. Guibourt, by his process, obtained 52 per cent. from the kernels, equivalent to about 35 per cent. from the seeds. Croton oil consists chiefly of the glycerides of stearic, palmitic, myristic, lauric, and oleic acids. There are also present, in the form of glycerin ethers, the more volatile acids, as formic, acetic, isobutyric, and isovalerianic acids. The volatile part of the acid yielded by croton oil contains, moreover, an acid of the oleic series, named by Geuther and Frölich *tiglic* or *tiglinic acid*, $C_8H_{15}O_2$. It is isomeric with angelic acid, but the melting points (angelic acid 45° C., tiglic acid 64° C.) and the boiling points (angelic acid 185° C., tiglic acid 198.5° C.) differ. *Crotonic acid*, $C_8H_{15}O_2$, was thought by Schlippe to be present, but later investigation does not confirm the statement. *Crotonol*, announced by Schlippe as the vesicating principle of the oil, has likewise been found only by the discoverer.

In 1823 John Nimmo of Glasgow, found that about 45 per cent. of croton oil is soluble in alcohol, the insoluble 55 per cent. being inert. Recent researches have shown that the percentage of soluble portion varies greatly. (See also below.) According to Senier, confirmed by Binz, Kobert, and others, it increases with the age, freshly expressed oil containing only 20 per cent., oil over four years old 60 per cent. In this soluble portion Buchheim found

² *Extraction by ether.*—Having washed and dried the seeds, grind them in a coffee mill, and form a soft paste with ether. Introduce this into a narrow percolation tube, and gradually pour ether upon it until it is exhausted. Evaporate the ether by means of a water bath, and filter the remaining oil. (*J. P. C.*, Aout, 1862.)

Extraction with carbon disulphide.—The seeds, well bruised, are introduced into a bottle with three times their weight of carbon disulphide, well rectified; the mixture is allowed to stand, with frequent agitation, for 24 hours; the whole is then poured upon a cloth and rapidly expressed. The residue is similarly treated with twice its weight of the disulphide, and expressed, after standing as before. The products of the two macerations are mixed, then filtered in a covered funnel, and finally submitted to distillation, by means of a water bath, in a glass retort, at the temperature of 71.1° or 76.8° C. (160° or 170° F.). The disulphide should be recovered by condensing its vapor in a refrigerated receiver. The oil is to be poured into a dish, to show that it contains none of the disulphide, and then introduced into a bottle and closely stoppered. (*J. P. C.*, 3e sér., xxxi. 28.)

an acid, *crotonolic acid* or *crotonoleic acid*,¹ which he believed to be the active principle. It is an oily substance, readily decomposable, having the character of a weak acid, and forming various salts. It is freely soluble in alcohol, and is extremely irritant to the skin and the mucous membrane. As pointed out in 1889 by Stillmark and Kobert, croton seeds contain one or more toxic albuminoids, which have been especially studied under the name of *croton* by Elfstrand.² Dunstan and Boole (*Proc. Roy. Soc. London*, lxiii., 1895) found that crotonoleic acid, prepared by the method of Kobert and Hirscheydt, is a mixture of inactive oily acids and a resinous substance having extraordinary power as a vesicant, for which they have proposed the name of *croton resin*, assigning to it the empirical formula $C_{15}H_{15}O_4$, and the molecular formula $(C_{15}H_{15}O_4)_2$, or $C_{30}H_{30}O_8$. It is described as a hard, pale yellow resin, nearly insoluble in water and benzene, but readily dissolved by alcohol, ether, and chloroform. It is neither a glyceride, a ketone, nor an aldehyde.

Croton oil, as found in commerce, varies greatly in color, from a pale yellow to a dark reddish brown. That imported from India is usually pale, that expressed in Europe dark, like the deepest-colored sherry. Its consistence is rather viscid, and is increased by time. Its odor is faint, but peculiar, its taste hot and acrid, leaving in the mouth a disagreeable sensation which continues for many hours. It is officially described as "a pale yellow or brownish-yellow, somewhat viscid, and slightly fluorescent liquid, having a slight fatty odor, and a mild, oily, afterwards acrid and burning taste (*great caution is necessary in tasting*). When applied to the skin, it produces rubefaction, or a pustular eruption. Specific gravity: 0.935 to 0.950 at 25° C. (77° F.). It reddens blue litmus paper moistened with alcohol. When fresh it is soluble in from 55 to 60 parts of alcohol, the solubility increasing by age; freely soluble in ether, chloroform, carbon disulphide, and in fixed or volatile oils. When gently heated with twice its volume of absolute alcohol, it forms a clear solution from which the Croton Oil should separate on cooling. If to 2 Cc. of Croton Oil 1 Cc. of fuming nitric acid and 1 Cc. of water be added, and the mixture

vigorously shaken, it should not solidify either completely or partially, after standing for one or two days (absence of *other non-drying oils*). Croton Oil saponified by alcoholic potassium hydroxide T.S. should show a saponification value of from 212 to 218 (see PART III, Test No. 99). If 0.3 Gm. of Croton Oil be dissolved in 10 Cc. of chloroform in a 250 Cc. bottle or flask, and 25 Cc. of a mixture of equal volumes of alcoholic iodine T.S. and alcoholic mercuric chloride T.S. added, and if, after standing for four hours, protected from light, 20 Cc. of potassium iodide T.S. be added and the mixture diluted with 50 Cc. of water, on titrating the excess of iodine with tenth-normal sodium thiosulphate V.S., an iodine value of not less than 102 nor more than 105 should be obtained (see Part III, Test No. 51)." *U. S.*

"Specific gravity 0.940 to 0.960. Entirely soluble in *absolute alcohol*. Freely soluble in *ether* and *chloroform*. An alcoholic solution should not reddens moistened *blue litmus paper*. If to 2 cubic centimetres 1 cubic centimetre of *fuming nitric acid* and 1 of *water* be added, and the mixture be shaken vigorously, it should not solidify, either completely or partially, but only thicken slightly, after standing for two days (absence of *other non-drying oils*)." *Br.* The oil is wholly soluble in ether and oil of turpentine. Its relations to pure alcohol differ somewhat with the variety of the oil. That obtained by expression in England was formerly wholly and readily soluble, but, according to Harold Senior, the croton oil now produced acts towards alcohol as do foreign oils (*P. J.*, 3d ser., xiv. 704), forming a solution which is permanent at ordinary temperatures, while the India or pale oil forms an opaque mixture, which becomes clear and uniform upon being heated, but separates on standing into two portions, one consisting of alcohol somewhat diminished in bulk, the other of the oil correspondingly increased in bulk by retaining a portion of the alcohol. It is probable that the difference in color, and in their relations to alcohol, between the India and English oils may be owing to a change in the kernels from being kept, and to the age of the oil. It is known that croton oil is often adulterated with other fixed oils. In the *Br. Pharm.* of 1864 it was given as a test of the purity of the oil expressed from the imported seeds, that when agitated with an equal volume of alcohol and gently heated it forms a clear solution, from which about three-fourths of the oil separates on cooling; but the statement is asserted to be untrue of the English expressed oil, though correct of the imported. The test was intended to detect the presence of castor oil, which would be dissolved by the alcohol and thus occasion a diminution of the bulk. It has been omitted in the present British Pharmacopœia.³

¹ *Crotonoleic acid* may be readily prepared by treating the portion of croton oil soluble in alcohol with a hot saturated solution of baryta in a water bath, washing the stiff white paste that forms with cold distilled water to remove excess of baryta and barium compounds with acetic, butyric, and tiglic acids, repeatedly treating with water, and lastly agitating with ether, which takes up only the barium oleate and crotonoleate. The crotonoleate is separated by dissolving it out in alcohol, decomposing it carefully with sulphuric acid, and the solution containing the free acids carefully evaporated. See also *Kobert's Arbeiten*, 1890, p. 30.

² Croton is described as a yellowish powder, yielding about 21 per cent. of ash, soluble in water, and possessed of such active poisonous properties that the subcutaneous lethal dose for the rabbit is from 0.05 to 0.08 Gm. per kilo. It attacks the blood corpuscles as well as the centric nervous system, and, indeed, probably affects all protoplasm. (*On Some Toxic Albumins*, Upsala, 1897.)

³ Malsch detected croton oil in any mixture by the following plan. The suspected oil is agitated with an alcoholic solution of sodium or potassium hy-

(See U. S. official test, page 886.) For tests for croton oil, including iodine and acid numbers, see *Ph. Rev.*, 1897, 113.

According to M. Burrough, who was for some time in India, much of the oil there prepared is derived from the seeds of *Jatropha Curcas*, or *Curcas purgans*, the so-called *Barbados nuts*. This oil, though weaker than the genuine, was said by Burrough to be an efficient cathartic in the dose of three or four drops (0.15 or 0.2 Cc.). Hamilton states that croton seeds are afforded by *Croton pavana*, growing in Ava and Bengal, and probably a portion of the croton oil of commerce is obtained from these seeds. These facts may explain some of the discrepancies which have been observed in the effects of the oil.

Uses.—Croton oil is a powerful drastic purgative, in large doses apt to excite vomiting and severe griping pains, and capable, if immoderately taken, of producing fatal effects. It acts with great rapidity, frequently evacuating the bowels in less than an hour, and generally exciting a rumbling sensation in half that period. It possesses also great advantage in the minuteness of the dose, on account of which it may frequently be given when we should fail with more bulky medicines, as in *mania*, *coma*, and the cases of children. A drop placed on the tongue of a comatose patient will generally operate. Though long used in India, and known for two centuries to the Dutch physicians, it did not attract general notice till about 1820, when it was introduced into England by Conwell. It is chiefly employed in cases of *obstinate constipation*, in which it often produces the happiest effects after the failure of other medicines, but it may also be advantageously used in almost all cases in which powerful and speedy purging is demanded, especially where an irritation of the gastric mucous membrane and a derivative action are desired. The seeds are said to have been used successfully in India, in *amenorrhœa*. Applied externally, the oil produces inflammation of the skin, attended with pustular eruption, and has been used in this way in *rheumatism*, *gout*, *neuralgia*, *glandular* and other *indolent swellings*, and *laryngeal* and *pulmonary diseases*. It should be diluted with three parts of olive oil, soap liniment, oil of turpentine, or other convenient vehicle, and applied as a liniment twice or oftener in twenty-four hours. Sometimes the insusceptibility of the skin is such as to require its application undiluted. The oil may also be applied externally, in the form of a plaster, made by incorporating one part of it with four parts of lead plaster, melted by a very gentle heat. Sometimes it appears to produce inflammation in parts dis-

tant from those to which it was directly applied. It has been said that four drops, used externally by friction around the umbilicus, will produce a purgative effect, but this is denied by Barlai of Tuscany, who states that it is only when the oil is applied to the skin divested of the cuticle that it will operate upon the bowels. *Nævus* has been cured by the introduction of croton oil into the little tumor by means of needles.¹ The oil is most conveniently administered in the form of pill. A safe and convenient plan is to make two drops into four pills with crumb of bread, and to give one every hour until they operate. The oil may also be given in capsules, cachets, or emulsion.

Crotonoleic acid has been shown by Kobert to be a very active irritant poison, much more harsh and severe in its influence than croton oil itself. Hirscheydt has found that its salts injected into the blood are extremely powerful depressants to the circulation. It has appeared in commerce, but after trial has been found by Hirscheydt to act badly as a practical remedy. It probably also varies greatly in purity. Ten milligrammes were found by Hirscheydt to be very uncertain in their purgative effect, while large doses commonly produced excessive gastro-intestinal irritation. The superiority of croton oil over the acid probably depends upon the fact that the acid exists in it chiefly in combination with glycerin, and that this crotonoleic glyceride acts with comparative kindness because of the slow decomposition and setting free of the acid which occur in the intestines. This being the case, it follows as a corollary that old, acid croton oil must be more irritant than the fresher and nearly neutral oil. Kobert has confirmed this conclusion by actual trial, and asserts that the neutral oil should always be preferred in practice, and that the acid oil, which is official in the German Pharmacopœia, should be rejected.

Dose, one-half to two minims (0.03 to 0.12 Cc.).

Off. Prep.—Linimentum Crotonis, *Br*.

OPII PULVIS. U. S.

POWDERED OPIUM

(ὀπί-ἰ πῦλ'ῑς)

"Opium dried at a temperature not exceeding 85° C. (185° F.) and reduced to a very fine powder. Powdered Opium, for pharmaceutical and medicinal purposes, when assayed by the process given under *Opium*, should yield not

dioxide, and the solution, having been separated, is saturated with hydrochloric or sulphuric acid. If croton oil be present, its acid principle will rise to the surface in the form of an oil, which when applied to the skin will produce the peculiar eruptive affection excited by croton oil. (*A. J. P.*, 1880, 307.)

¹ *Croton Oil Crayons*.—In order to prevent the spreading of croton oil beyond the limits intended, Limousin prepared crayons by melting 1 part each of cacao butter and white wax in a small glass flask, and then adding 2 parts of croton oil, taking care to close the orifice of the flask at once with a cork. When the mixture begins to get thick, it is poured into cylindrical moulds, where it speedily solidifies. These crayons may be made of a thickness of about 8 or 9 millimeters ($\frac{1}{2}$ inch), and may be covered with tin foil to protect them from change. (*N. R.*, May, 1877.)

less than 12 percent. nor more than 12.5 percent. of crystallized morphine. Powdered Opium of a higher percentage may be brought within these limits by admixture with Powdered Opium of a lower percentage or powdered sugar of milk in proper proportions." *U. S.*

Poudre d'Opium, *Fr. Cod.*; Opiumpulver, *G.*; Polvo de opio, *Sp.*

The strength of powdered opium has been altered in the last revision, the *U. S. P.* 1890 requiring that it should yield not less than 13 nor more than 15 per cent. of crystallized morphine when assayed by the *U. S. P.* 1890 process. The *U. S. P.* (8th Rev.) requires that it shall yield not less than 12 per cent. nor more than 12.5 per cent. of crystallized morphine. It will be observed that the range has been reduced and figures lowered, but the assay process is now more rigid and a purer morphine is demanded. For assay and preparations see pp. 903, 910.

Dose, one-half to one grain (0.032 to 0.065 Gm.).

Opium is generally believed to be derived exclusively from *Papaver somniferum*, though every species of poppy is capable of yielding it to a greater or less extent, and some authors assert that *Papaver orientale* is its real source.

The United States, British, and French Pharmacopœias recognize only the first-mentioned species.

Papaver somniferum, L., *Sp. Pl.* (1753) 508; Willd., *Sp. Plant.* ii. 1147; B. & T. 18.—There are several varieties of this species, of which the two most prominent are distinguished by the titles of the white and the black poppy, derived from the color of their seeds. It is the former (var. *P. album*, DC.) which is usually described as the proper opium plant. The *white poppy* is annual, with a roundish, smooth, erect, glaucous, often branching stem, usually rising two or three feet in height, but sometimes five or even six feet in favorable situations. The leaves are large, variously lobed and toothed, and alternately disposed on the stem, which they closely embrace. The flowers are terminal, very large, and of a white or silver-gray color. In India they appear in February, in Europe and the United States not earlier than June, July, or August. The calyx is smooth and composed of two leaves, which fall when the petals expand. These are usually four in number, but there is a variety in which the flower is double. The ovary is smooth and globular, supports a radiated stigma, and is surrounded by numerous short and slender filaments, with erect, oblong, compressed anthers. The capsule is smooth and glaucous, rounded, from two to four inches in diameter, somewhat flattened at the top and bottom, and crowned with the persistent stigma, the diverging segments of which are arranged in a circle upon the summit. It contains numerous minute white seeds, which when perfectly ripe escape through small openings beneath the stigma. In the *black poppy*, the flower, though sometimes white, is usually violet-colored or red, the capsule somewhat smaller and more globular, and the seeds of a brown or blackish color.

All parts of the poppy contain a white, opaque, narcotic juice, but the leaves, analyzed by Blondeau, yielded none of the active principles by which opium is characterized. (*J. P. C.*, vii. 214.) It is in the capsule that the juice most abounds and the virtues of the plant chiefly reside. Hence this part is sometimes employed medicinally. (See *Papaver*.) The seeds are destitute of narcotic properties, and are even used as food. The Romans employed them in the preparation of various dainties. They abound with a bland oil, called commercially *poppy seed oil*, which may be extracted by expression. It is of a straw-yellow color, without odor, and of a pleasant almond taste. It is without narcotic properties, and much resembles olive oil, as a substitute for which and an adulterant of which it is very largely used on the continent of Europe. It has a low congealing point, thickening only at -15° C. (5° F.) and solidifying at -20° C. (-4° F.). The black variety is specially used for the expression of oil, as its culture is easier, and the oil percentage in both varieties is practically the same, ranging between 50 and 60 per

cent. As the oil cake generally retains about 8 per cent. of the oil, the yield by expression is from 42 to 50 per cent. Poppy oil contains the glycerides of stearic and palmitic acids, together with those of linolic, linolenic, and oleic acids. Of the liquid fatty acids, linolic constitutes about 65 per cent., oleic 30 per cent., and linolenic 5 per cent. Myristic and lauric acid seem to be absent. The oil is an article of much importance on the continent of Europe, particularly in France and Germany, where it is employed for culinary and pharmaceutical purposes, in painting and the manufacture of soap, and in other ways, as a substitute for olive oil. The poppy does not appear to elaborate the milky fluid in which its narcotic properties reside before a certain period of its growth, for we are told that, in Persia, the young plants which are pulled up to prevent too thick a crop, are used as potherbs, and the *μῆκον* of the Greeks, which is believed to be identical with the *Papaver somniferum*, is said by Hippocrates to have been nutritive.

Though generally believed to be a native of Asia, this species of poppy grows wild in the south of Europe, and even in England, whither its seeds are supposed to have been brought at a very early period. It was cultivated by the ancient Greeks, and is mentioned by Homer as a garden plant. It is at present cultivated very extensively in India, Persia, China, and Asiatic Turkey, for opium, and in certain parts of Europe chiefly for its seeds. Attempts have been made both in Europe¹ and the United States to produce opium from the poppy, but although it is possible to obtain the product, commercial success has not been and probably never will be achieved in America because of the cost of labor. A very good quality of opium is said to have been produced in Australia. (See *Australian Journal of Pharmacy*, Nov. 1887.)

¹ Various attempts have been made in England to cultivate the poppy, all of which have resulted in commercial failure. (For particulars, see Seventeenth edition U. S. D.; also *Edinb. Phil. Journ.*, l. 258.) The same may be said of the attempts to cultivate opium in France, which have apparently ceased since the death of Aubergier, who devoted much time and money to the subject. (For particulars see 15th ed. U. S. D.; also *P. J.*, xv. 693.)

In spite of the prohibitions of the Imperial government, the production of opium is said to be greatly on the increase in China, the cultivation of the poppy paying much better than that of wheat. (*P. J.*, ix. 1878.)

In 1865, P. Robertson of Campbell Co., Virginia, produced opium which yielded to the analysis of I. J. Graham 4 per cent. of morphine, besides narcotine. (*A. J. P.*, 1867, p. 50.) H. Black of Bolivar, Tennessee, produced an opium from which E. S. Wayne obtained 30.2 per cent. of morphine. (*Ibid.*, Jan. 1868.) In 1868 considerable interest was aroused by the statements of W. C. Wilson, which were, however, proved by Procter to be incorrect. (See 14th and 15th eds. U. S. D.) Very fine opium has been produced by J. H. Flint of California (*A. J. P.*, 1874, p. 105); also in Minnesota, by E. Weschke (*Contributions Dep. Pharm. University of Wisconsin*, 1886), but in the opinion both of Flint and of Weschke the high price of labor forbids the profitable production of opium in the United States. For an account of North Carolina opium, see *Proc. A. Ph. A.*, 1894, 286; also *A. J. P.*, 1896, 435; also *Proc. A. Ph. A.*, 1904, 438.

The opinion that a hot climate is not necessary for the production of the narcotic principles has the support of Guibourt (*J. P. C.*, Sept. 1867, p. 222), and would seem to be established by the facts that the opium of Anatolia is richer in morphine than that of the much hotter regions of Bengal and Upper Egypt, and that, while Smyrna opium seldom yields more than 12 per cent. of morphine, that produced in the north of France yields from 20 to 24 per cent. (Bussy, *Ibid.*, p. 221.)

Opium is obtained from the capsule of the poppy in a manner almost the same as that described by Dioscorides eighteen hundred years ago. A few days after the petals have fallen from the flower, when the capsule is approaching maturity, horizontal incisions into the capsule are made, usually with a several-bladed knife, care being taken not to penetrate the cavity. The white juice which exudes is allowed to harden for twenty-four hours, when it is scraped off by means of a large, blunt knife, a portion of the epidermis of the capsule being removed and constituting about six to ten per cent. of the product. In some places the poppy-head yields opium but once, but in Persia and probably other very hot countries the operation is repeated two or three times after periods of rest. The quality of the product depends largely upon the weather; if this is very hot and dry, the juice will be scanty and very thick, but if the weather is moist the product will be larger but more aqueous. After gathering, the poppy juice is worked up into opium in a manner which differs in different producing countries. An opium-like substance has been in past times, and perhaps even is at present in some districts, produced by making an aqueous extract from the nearly ripe capsules of the poppy. According to the writings of Dioscorides the ancient Greeks were acquainted with both processes of producing the drug from the poppy capsule. The term *ὀπιον*, derived from *ὀπός*, juice, they applied to the substance procured by incisions, which answers precisely to the modern opium. The inspissated expressed juice they called *μυκάνιον*, from *μῆκον*, the name of the plant.

Commercial History.—Commerce is supplied with opium chiefly from Hindostan, Persia, Egypt, and Asiatic Turkey.¹ Immense quantities are produced in the Indian provinces of Bahar and Benares, and in the more interior province of Malwa. The opium of Hindostan is distributed extensively through continental and insular India, where it is habitually employed as a narcotic-stimulant. Great quantities are also sent to China, into which it finds an easy entrance, notwithstanding prohibitory laws.² Much was formerly imported by the

¹ For an elaborate account of methods of opium production in India, see *P. J.*, vol. xx. 178, also in Turkey and Asia Minor, see *J. P. C.*, 3e sér., xiii. 105; *P. G.*, March, 1854; *A. J. P.*, 1863, 362; also 14th edition U. S. D.

² The India-Chinese opium trade, which has given rise to so many wars and controversies, is, according

East India Company into England, through which a small proportion reached our own country. For various reasons India opium no longer enters Western commerce to any extent. It is produced in Hindostan chiefly under government supervision. The drug as first obtained is semi-liquid, owing to the excessive dews, but is allowed to drain and dry by spontaneous evaporation until only 30 per cent. of moisture is left, when it is taken to the government factories. Great care is exercised to prevent adulteration. In the factories it is worked up with the drainings (known as *passēwā*), poppy petals, and ground poppy plant into balls of standard strength. These are called "*cakes*," are about six inches in diameter, and are prevented from adhering by being rolled in the ground poppy plant. *Malwa* opium is a variety not made in Hindostan proper nor under government supervision. Its quality varies greatly. Of the opium produced in Persia, very little is brought to this country. Much was formerly produced in Upper Egypt, especially in the district of ancient Thebes, which was supposed to yield it in greatest perfection, hence the term *Opium Thebaicum*, and the old name of laudanum, *Tinctura Thebaica*.

Turkey opium is produced in Anatolia, and shipped chiefly from the port of Smyrna. It is brought to the United States either directly from the Levant or indirectly through different European ports. The amount of crude opium imported in 1904 was 573,055 lbs., valued at \$1,255,115, and of opium prepared for smoking, 142,813 lbs., valued at \$1,094,988. Turkey opium usually comes to us in masses of irregular size and shape, generally more or less flattened, covered with leaves or the remains of leaves, and with the reddish fruits of some species of *Rumex*, which are said to be absent in the inferior kinds, and may therefore be considered as affording some indication of the purity of the drug. We may account for this circumstance upon the very probable supposition that these fruits are removed during the operation which the masses undergo in the hands of the merchants after leaving those of the cultivators. We are told by some French

to the English consul at Shanghai, "likely to disappear by a sort of painless extinction," the importation from India into China having fallen from nearly ten millions of pounds annually to less than seven millions. This change is not the result of any lessening in the use of opium as an intoxicant by the Chinese, but to the increase of poppy cultivation throughout the Celestial empire. As much as 1,300,000 pounds of Chinese opium were in 1895 received in the Shanghai market from Western China alone. The cost of the native drug to the consumer is said to be exactly half that of the India opium. The importance of this matter is shown by the fact that in the season of 1894-95, 537,556 acres of land were under poppy cultivation in British India. The comparatively low price of the Chinese opium seems not to depend upon differences in quality. The percentage of morphine does not decide the value of smoking opium, certain opiums being preferred by the Chinese, although they contain a very small percentage of morphine. On examination of the Chinese opium, Frank Brown found it remarkably free from foreign materials. The percentage of morphine varies from 4.3 in the Kwie-chu opium to 11.3 in the Szechuen opium. For further details, see *P. J.*, iv. and lvii.

writers that extensive frauds are practiced at Marseilles in this branch of commerce. The opium taken thither from the Levant is first softened, and then adulterated with various matters which are incorporated in its substance. To use a strong expression of Guibourt, they make the opium over again at Marseilles. According to A. T. Thomson, one-fourth part of Turkey opium generally consists of impurities. Sand, ashes, the seeds of different plants, extracts of the poppy, *Lactuca virosa*, *Glycyrrhiza glabra*, and *Chelidonium glaucum*, gum arabic, tragacanth, salep, aloes, even small stones and minute pieces of lead and iron, are mentioned among the substances employed in the sophistication of the drug. Tschirch (*A. J. P.*, 1898, 488) proposes the use of the Roentgen ray in detecting such adulterations. Landerer of Athens, was informed by a person who had been engaged in the extraction of opium, that grapes, freed from their seeds and crushed, were almost universally mixed with the poppy juice, and that another adulteration consisted of the epidermis of the capsules and stem of the plant, pounded in a mortar with the white of an egg. (*A. J. P.*, xv. 238.) According to Wilkins, who witnessed the collection of opium, the inspissated juice of the grape, thickened with flour, is often used for the same purpose. (*P. J.*, xiv. 400.)¹

¹ The great importance of opium renders it desirable that all its commercial varieties should be accurately described, and their relative value, so far as possible, ascertained. The varieties of this drug may be discussed according to the countries in which they are produced, an arrangement which we here adopt.

I. TURKEY OPIUM.—This title belongs to the opium produced in the Turkish province of Anatolia, and exported from Smyrna and Constantinople. According to some authorities, there is no essential difference between the parcels of the drug brought from these two ports. Others maintain that they are distinct varieties, differing in their interior structure, and probably also in the precise place of their production and the mode of their collection. The truth probably is that most of the opium shipped at Constantinople is produced in the more northern parts of the opium districts of Anatolia, while that from Smyrna is collected in the provinces more convenient to the latter city, and, though it is possible that an identical drug may often be brought from the two ports, yet there are grounds for regarding it under different varieties, as derived from these different sources. There can be little doubt also that a portion of opium which is taken to Constantinople is produced in Macedonia in Europe, which must, therefore, be added to the opium producing regions.

1. *Smyrna Opium*.—This is the variety which is, beyond all comparison, most abundant in our markets, and it is from this that the ordinary descriptions of opium are drawn up. It comes to us in masses of various size, usually from half a pound or somewhat less to a pound in weight, sometimes, though rarely, as much as two or even three pounds, originally, perhaps, of a globular form, but variously indented, and rendered quite irregular in shape by the pressure to which they have been subjected, while yet soft, in the cases which contain them. Sometimes they are even pressed out into flat cakes. As brought into market, the lumps are usually hard on the outside, but still soft within. They are covered externally with the remains of leaves, and with the reddish fruits of a species of *Rumex*, which have no doubt been applied in order to prevent the surfaces from adhering. Notwithstanding, however, this coating, the masses sometimes stick together, and two or more become consolidated into one. In this way the fact may be accounted for, that the seeds of the *Rumex* are occasionally found in the interior of the masses. In the finer parcels of Smyrna opium the

The adulteration of opium has given rise to much complaint on the part of pharmacists, and various plans of customs legislation have been

color internally is light brown; in the inferior it is darker. A peculiar character of this variety is that, when a lump of it is cut into and then carefully torn, numerous minute shining tears are observable, particularly under a microscope, bearing some resemblance to small seeds, but readily distinguishable by pressure between the fingers. They are undoubtedly formed from the drops of juice which escape from the incisions in the capsules, and which, according to Bélon, are allowed to concrete before they are removed. From the account of the same author it appears that after the juice has been collected it is not subjected to the process of kneading or beating, as in the case of other varieties of the opium; so that the tears preserve their original shape in the mass. It is probably owing to the peculiar mode of collecting Smyrna opium, that minute pieces of the skin of the poppy capsules are found intermingled in the mass, these being separated in the process of removing the adhering tears. In the best specimens of Smyrna opium, these fragments of the capsules are the only impurities. This variety of the drug is of very different qualities, the finest kinds yielding, according to Merck, as much as 13 per cent. of pure morphine, while from some very bad parcels he could not procure more than 3 or 4 per cent. In these inferior specimens the color is darker, the odor is often musty, and there is very generally more or less mouldiness both upon the surface and in the interior of the masses, indicating perhaps too much moisture in the opium originally, or its subsequent exposure to an injurious degree of dampness. Good Smyrna opium ought to yield 10 to 11 per cent. of morphine. Christison, however, states that he has not been able to procure more than 9 per cent. from the finest Smyrna opium. According to Landerer, little of the opium is produced in the immediate neighborhood of Smyrna, the greater portion being brought, on the backs of camels, from a distance of from ten to eighteen days' journey. (*J. P. C.*, 3e sér., xxiii, 33.) The same writer states that the opium is chiefly prepared at Kara-Hissar, near Magnesia. The incisions are generally made before sunrise. The juice is partly caught in mussel-shells, and dried in the sun. This is considered the best. Every evening the juice which has dried upon the capsules is scraped off, with a portion of the epidermis. The poppy is then cut down, and stripped of its leaves, which are boiled in water, and the liquor is evaporated to the consistence of an extract. With this the inspissated juice is incorporated, and the mixture is then formed into cakes, wrapped in poppy leaves, and placed on shelves to dry. (*See A. J. P.*, xxiii, 251.) It is very evident, from the interior structure of the best Smyrna opium, that it has not been prepared in the way described by Landerer, though his account is probably true in reference to inferior varieties.

2. *Constantinople Opium*.—Most of the Constantinople opium is in lumps from half a pound to two and a half pounds in weight, and scarcely distinguishable in exterior appearance from those of the former variety, being equally irregular in shape, and in like manner covered with the fruits of the *Rumex*. According to Merck, however, it often differs strikingly from the Smyrna opium in its interior constitution, being wholly destitute of the tears which characterize that variety. This would indicate some difference in the mode of collecting and preparing the juice. In the case of the Constantinople opium it is probably removed from the capsules before concretions. Merck says that he has not discovered in this variety those minute portions of the poppy capsules which are usually present in Smyrna opium. The average quality of the Constantinople opium, as above described, is about equal to that of the drug from Smyrna, but it appears to be occasionally purer, as Merck obtained from one specimen as much as 15 per cent. of pure morphine. R. Bauer of Constantinople, in 1867 denied that any of the varieties produced near Smyrna contain tears, except the single one from Magnesia. (*N. R. Pharm.*, xvi, 751.)

In an account, by Bourlier, of the culture of the poppy and collection of opium in Bithynia, a province of Asia Minor, near Constantinople, it is stated that the lumps, when formed out of the concrete juice, are enveloped in poppy leaves, and no mention is made of the use of the *Rumex* fruits to prevent adhesion. It is the opium here collected which, according to Bourlier, is known throughout the Levant and in Europe as Constantinople opium.

suggested by which it has been thought that these adulterations could be prevented. It is, however, obviously impossible to pronouncedly

The same authority states that the yolk of egg is sometimes largely used for adulterating opium—a fraud which may be detected by the large proportion of fatty matter which the adulterated drug yields to ether, and by the impossibility of drying it so as to fit it for pulverization. (*Ann. Thé.*, 1859, p. 4.)

Guibourt describes another variety of Constantinople opium of much inferior character. "It comes," he observes, "in small, flattened cakes, sufficiently regular and of a lenticular shape, from two to two and a half inches in diameter, and always covered with a poppy leaf, the midrib of which divides the surface into two equal parts. It has an odor similar to that of the preceding variety, but feebler, and it becomes adre in the air. It is more mucilaginous than Smyrna opium, and contains only half as much morphine." These characters are obviously those of Egyptian opium, and, though the parcels which came under the notice of Guibourt may have been imported directly from Constantinople, it is highly probable that they were originally from Alexandria. Stettner of Trieste, though well acquainted with the opium commerce of that port, recognizes no such Constantinople opium as that described by Guibourt. (*Ann. Pharm.*, xxiv, 65.) According, however, to Bauer, the opium collected in the districts nearest Constantinople is mostly in small pieces, often of only two or three ounces, which are always invested with poppy leaves, or more rarely with grape leaves, generally smooth, and without *Rumex* fruits, and this description corresponds with Guibourt's. (*N. R. Pharm.*, xvi, 754.)

A number of varieties of opium produced in European and Asiatic Turkey circulate more or less in Austria and other parts of Germany, which have been described by C. Finckh in *Buchner's Repertory* (vol. xvi., p. 749), and of which we propose to give a brief account here.

Opium of Géwé or *Géwé* is gathered from a poppy with red flowers, and comes in the form of small rounded cakes, weighing 2 or 3 ounces, enveloped in the leaves of the poppy, with a smooth and shining surface, which seems to be divided into two halves by the median nerve of the leaf. The interior is in layers of light- and deep-colored opium; and its yield of morphine is from 12 to 15 per cent.

Opium of Amasia differs from the preceding only in this, that there are two enveloping poppy leaves, placed crosswise, and with their lower surface outward, so as to give a rugose appearance to the cakes. In the interior the mass is homogeneous, but is very analogous to the *Géwé* opium.

Opium of Malatia is in small leaves, round or somewhat oval, from 4 to 5 ounces in weight, made with the greatest care, and enveloped in poppy leaves, with a rugose surface, and the median line corresponding to the middle of the leaves. The borders of these are frequently deprived of the leaf. The substance of the leaf is homogeneous, but generally poor in morphine.

Opium of Magnesia is in irregular cakes or loaves, from 1 to 4 ounces in weight. They are covered first with a layer of *Rumex* fruits, and afterwards with poppy and vine leaves, and owe their irregular form to the envelopes, for originally they are rounded. The interior is composed of agglutinated tears, and is of excellent quality.

Opium of Salonica, or of *Kutchina*, has a strong analogy in all respects with that of *Géwé*, for which it is often substituted. (*See analysis by A. R. L. Dohme, Proc. A. Ph. A.*, 1893.)

The following represent the varieties in which Smyrna opium appears in the market:

The *Opium of Balukhissar*, which is the chief source of the Smyrna opium, is in cakes of from 4 to 12 ounces, irregular, though originally globular-ovoid. They are covered with *Rumex* fruits and present, besides on their surface, poppy leaves irregularly applied. The mass is formed of tears lighter or deeper colored, and is so rich in morphine as to cause this variety to be always sought for in the market. (*See analysis by A. R. L. Dohme, Proc. A. Ph. A.*, 1893.)

The *Opium of Cataya* is generally in lumps half as large as the preceding, which it approaches closely in its characters and in its yield of the alkaloid.

The *Opium of Taushan* or *Taushan* is in irregular lumps, twice as long as broad, and weighing from 3 to 5 ounces. The mass consists of tears, and is carelessly enveloped with the poppy leaf and a few *Rumex* fruits. This variety is rich in morphine.

affect the action of the semi-barbarians who are engaged in the cultivation of opium, by any American legislation. Usually the substances

The *Opium of Angora* or *Engiri* is readily known by its under surface being covered with only one leaf of the poppy. The masses, being almost spherical, appear to have been originally in balls. Their weight is from 6 to 8 ounces, the interior homogeneous, and the quality inferior.

The *Opium of Kara-Hissar* is in balls, flattened beneath, of the weight of 6 or 8 ounces, and covered with poppy leaves and Rumex fruits. Though carefully prepared, this variety formerly, from its deficiency in morphine, was of inferior quality; but it has improved of late years. (See analysis by A. R. L. Dohme, *Proc. A. Ph. A.*, 1893.)

The *Opium of Cigusti* is in irregular loaves, 6 or 8 ounces in weight, enveloped in poppy leaves and Rumex fruits. Though rarely falsified, it often contains fragments of the poppy capsules, and forms a mass sometimes of distinct tears, sometimes not. Occasionally rich, it is almost always mixed with the various forms of Smyrna opium.

Finckh has noticed the following adulterations: opium of Macedonia, with clay; of Angora, with wax; of Amasia, with gum; of Taushan, with licorice; of Balukhissar, with melted pitch. He has even found an opium evidently made almost entirely of clay and cow dung. The opiums of Macedonia are most frequently adulterated. (*J. P. C.*, Nov. 1869, 377.)

Bulgarian Opium has been met with in European commerce. (*C. D.*, 1893, 733.)

II. EGYPTIAN OPIUM.—This formerly occurred in flat roundish cakes, of various dimensions, sometimes as much as six inches in diameter and a pound in weight, usually, however, much smaller, and sometimes not weighing more than half an ounce. These cakes were either wrapped in a poppy leaf, so placed that the midrib divided the surface into two equal parts, or exhibited vestiges of such a covering. Occasionally the brown color of the opium was seen through the leaf, and the surface appeared as if uncovered, while the leaf was still present. The fracture was conchoidal and of a waxy lustre, and small fragments of it were translucent. Its color was usually redder than that of Smyrna opium, though sometimes dark. Some of the pieces, on exposure to the air, became damp and sticky on the surface, indicating the fraudulent addition of a deliquescent substance. The odor was similar to that of Smyrna opium, but weaker. It was an inferior variety, as the best of it, examined by Merck, yielded only 6 or 7 per cent. of morphine, and a specimen of it was found by J. Evans of Philadelphia, to contain not more than 3.55 per cent.

At one time there was a considerable exportation of opium from Egypt to Italy, but in 1903 the production of the drug in Egypt was practically abandoned, so that Egyptian opium is no longer a commercial variety.

III. INDIA OPIUM.—Little if any of this opium reaches our market. There appear to be two chief varieties of it,—one produced in Bahar and Benares, in the Bengal Presidency, and called *Bengal opium*, the other in the interior provinces, and designated by the name of *Malwa opium*. For minute description of Indian opium, see *P. J.*, xi., xii., abstracted *A. J. P.*, xxiv. 118; also *Pharmacographia*.

1. *Bengal Opium*, *Benares Opium*, *Patna Opium*. It is in round balls, weighing three pounds and a half, invested by a coating half an inch thick, composed of agglutinated leaves and poppy petals. The interior of the mass is of a brownish-black color, of the consistence of a stiff paste, and possessed of a high degree of the characteristic odor and taste of opium. The analyses of India opium vary decidedly in their results: Eatwell, 2.17 to 3.67 per cent. of morphine, 3.85 to 5.70 per cent. of narcotine; Procter (*Patna opium*), morphine, 5 per cent.; Flickiger and Hanbury (*Khandesh opium*), morphine, 6.07 per cent. (*Patna opium*), morphine, 8.6 per cent., narcotine, 4 per cent.; Solly (*Khandesh opium*), morphine, 7 per cent.; Watson (a number of varieties), 3.5 to 6.1 per cent. of morphine. (*P. J.*, xi. 362; *A. J. P.*, xxi. 194; *Pharmacographia*, 2d ed., p. 61.) India opium is, therefore, much inferior to the best Smyrna opium in its yield of morphine, while it is richer in narcotine. Its inferior character is possibly, in some degree, owing to the circumstance that the juice, after up, and consequently undergoes fermentation. (See *P. J.*, 1895, 208; *Ph. Centralh.*, 1895, 589; also *C. D.*, 1896, 134.)

which are used to adulterate the drug are inert, and therefore do no harm except by weakening its activity. The U. S. Custom House requires

Garden Patna Opium is prepared in Bahar with peculiar care, from juice which has not been suffered to undergo fermentation. It is in cakes three or four inches square, and about half an inch thick, which are packed in cases with a layer of mica between them. These cakes are without covering, hard, dry, and brittle, of a uniform shining fracture, and not unlike an extract in appearance. The color is sometimes almost black, and sometimes of a light brown, not unlike that of Egyptian opium. Christison states that it is much superior to the globular Bengal opium, and that some specimens are little inferior to Turkey opium in the proportion of morphine.

2. *Malwa Opium*.—This sometimes occurs in flat, roundish cakes, five or six inches in diameter, and from four to eight ounces in weight. In other instances it is in rectangular masses called bricks, or even in roundish balls. It seems never to be encased in poppy remnants. They are commonly quite hard, dry, and brittle, of a light-brown color, a shining fracture, a compact homogeneous texture, and free from mechanical impurities. The quality is very variable. A specimen of Malwa Opium described by Carson (*A. J. P.*, xxi. 195) broke with a rough fracture, which was of a blackish-brown color, here and there showing irregular oily spots. Procter obtained from it 9½ per cent. of morphine.

IV. PERSIAN OPIUM.—Opium has been produced in Persia for a great many years, but about 1870 a great stimulus seems to have been given to the cultivation of the poppy and to the improvement of the product. At that time it was described as follows: Sometimes it is in cylindrical pieces, about three and a half inches long and half an inch thick, wrapped in glossy paper, tied with a cotton thread, and each weighing about half an ounce; more frequently it is in short rounded cones weighing from 6 to 10 ounces; it also occurs in flat circular cakes. It is of a uniform consistence, but exhibits, nevertheless, under the microscope, small agglutinated tears, much less than those of Smyrna opium. It has the liver-brown color of Egyptian opium, a virose musty odor, and a very bitter taste, and, like Egyptian opium, softens in a moist atmosphere. The character of the opium has undoubtedly changed of late years. The most important local varieties of Persian opium appear to be the so called *Mesched opium*, which occurs in grayish-brown shining sticks, wrapped in paper, and *Ispahan opium*, of similar appearance, but of a purer brown color. According to the investigations of Schindelmeyer (*Ap. Ztg.*, 1904, 19) the *Mesched opium*, when freed from moisture, yields from 5.9 to 8.7 per cent. of morphine; while *Ispahan opium* has in it from 11.9 to 19 per cent. of the alkaloid. *Tschakida* of the Persians is a dark brown, blackish impure opium occurring in cakes prepared for smoking, and according to Schindelmeyer contains not more than 0.4 per cent. of morphine. Schindelmeyer states that Caucasian opium is largely adulterated with inspissated fruit juices, and frequently contains less than 2 per cent. of morphine.

According to Seidler, in 1903 the making of opium in Persia was flourishing, amounting to 3000 chests, each containing 60 kilogrammes, a year, but the drug is chiefly consumed in Persia by the opium smokers, and of that which was exported in 1903, 90 per cent. is said to have gone to Hong Kong and 10 per cent. to London and Egypt; so that very little of the Persian opium finds its way into the European market, and the last of its importation into the United States of which we have knowledge was in 1902. This opium was in irregular parallelopipedons; with a fracture smooth and almost conchoidal and showing no signs of tears; sometimes wrapped in deep-red paper, tied with yellow strings, or in other cases having a smooth oiled surface. According to Seidler, Persian opium now occurs in two forms, one in irregular masses with rugous irregularly fissured surface; the other in elongated squarish rods or masses, 0.7 to 1 centimeter in thickness, with a smooth surface and fracture. W. D. Howard examined a sample of the Persian opium sent to England as "perfectly pure," which yielded to him on analysis, without previous drying,—morphine, crystallized from alcohol, 10.40 per cent.; codeine, anhydrous, 0.29 per cent.; narcotine, 2.50 per cent.; thebaine, 0.57 per cent.; cryptopine, 0.09 per cent.; papaverine, a trace. He is unable to say whether it contained any narcelene. Rosengarten and Sons (now Powers-Weightman-Rosengarten Company) of

that opium, in order to enter the United States as opium, shall conform to the U. S. P. standard and contain not less than 9 per cent. of crystallized morphine. It would perhaps be better if this should be raised to 10 per cent., though it is a question whether shutting out the weakened and cheaper grades of opium does not injure the manufacture of morphine in the United States, and probably the present tariff legislation is sufficient. In China, opium is prepared for smoking by mixing it with various ingredients to give form and flavor. It occurs as a soft blackish paste and contains less than 9 per cent. of morphine, but is allowed to pass as an extract through the United States Custom House. In the fiscal year ending June, 1903, 208,043 pounds of this kind were received into America from the Chinese Empire, 4100 pounds from other countries. In 1904, 142,813 pounds were imported from the Chinese Empire, none from other countries.¹

Philadelphia, formerly used large quantities of the Persian opium in the production of morphine, obtaining from it an average of 10 per cent. of that alkaloid. In their more recent analyses the drug has yielded from 10 to 12.8 per cent. of actual morphine, the codeine in percentage varying very greatly apparently with the crop of the year; in some years the opium contained no codeine, in others 0.6 per cent.; commonly the percentage varies from 0.3 to 0.4 per cent.

V. MOZAMBIQUE OPIUM.—The poppy culture has been introduced into Mozambique for the production of opium for the Chinese market. A specimen of the product is said to have yielded 4 per cent. of morphine, 4.3 per cent. of narcotine, and 40 per cent. of moisture. (P. J., x, 63.)

VI. CHINESE OPIUM.—The U. S. duty upon opium is one dollar a pound, but the custom house authorities view the Chinese variety as an extract, and levy \$2 dollars a pound. It occurs in flat, oval cakes, wrapped first in white tissue, then in thin brown paper, labelled in Chinese characters with the name of the province and the seller. The color varies from dark brown to black; the fracture is sometimes granular, sometimes smooth; the odor usually strongly narcotic.

"BOSTON OPIUM," so called, was a sophisticated article.

The table below exhibits the results obtained by Guibourt in the analysis of various opiums. (J. P. O., Janv., Fév. et Mars, 1862.)

Opium Smoking.—By the various nations of the Orient opium is employed as an intoxicant by smoking in two ways. In Turkey and its neighboring countries it is placed upon tobacco, in a small pipe. In the East it is usually made into a very thick, almost plastic, liquid, and a drop of it is held over the flame of a small oil-lamp, and the resulting fumes inhaled through pipes of various forms. For an elaborate study of the chemistry of the opiums used for smoking in various countries, see *Ap. Ztg.*, 1903.

Moissan has found in opium smoke, morphine, pyrrol, pyridine with various homologues, acetone, and various hydropyridine bases, all of which are physiologically active. This analysis has been confirmed by Hartwich and Simon, who believe that the activity of the opium smoke depends not so much upon the morphine as upon the other products of the destructive distillation.

Opium is regarded as inferior when it has a blackish color, a weak or empyreumatic odor, a sweet or slightly nauseous and bitter taste, a soft, viscid, or greasy consistence, a dull fracture, or an irregular, heterogeneous texture, from the intermixture of foreign substances. It should not impart a deep-brown color to the saliva, nor leave a dark uniform trace when drawn over paper, nor form with water a thick viscid solution.

Properties.—Good opium has a peculiar, strong, narcotic odor, and a bitter, somewhat acrid taste. It is officially described as "in irregular, flattened, more or less rounded masses of variable size, externally grayish-brown, covered with remnants of poppy leaves and with occasional fruits of a species of *Rumex*; more or less plastic when fresh, but becoming hard on keeping; internally dark brown, somewhat lustrous; odor strong, narcotic; taste bitter and characteristic." U. S. When long chewed it excites much irritation in the lips and tongue, and may even blister the mouths of those unaccustomed to its use. Its color is reddish brown or deep fawn; its texture compact; its sp. gr. 1.336. When drawn over paper it usually leaves an interrupted trace of a light-brown color. It is often soft in the interior of the mass, and in this state is tenacious; but when exposed to the air it gradually hardens, and ultimately becomes brittle, breaking with a shining fracture, and affording, when pulverized, a yellowish-brown powder, which becomes adhesive upon a slight elevation of temperature. It readily inflames upon the application of a lighted taper. It yields its virtues to water, alcohol, and diluted acids, but not to ether. To all these menstrua it imparts a deep-brown color. Alcohol dissolves about four-fifths of it. Pelletier stated that the proportion taken up by water varies in the specimens. He never found the quantity of extract prepared with cold water to exceed 12 parts out of 16.

Chemical Constituents.—Much attention has been devoted to the chemical constitution of opium. It was through the researches into the nature of this substance that chemists were led to the discovery of the alkaloids, which are usually the active principles of the plants in which they are found, and have attracted much notice, and been applied so advantageously to the treatment of disease. To Sertürner, an apothecary at Kimbeck, in Germany, belongs the credit of having opened this new and most

Table showing percentage of morphine in varieties of opium (Guibourt).

important field of research. In the year 1803 Derosne made known the existence of a crystallizable substance which he had discovered in opium, and which he erroneously believed to be the active principle. In the following year Seguin discovered another crystallizable body, which experience has proved to be the true narcotic principle of opium, but he did not fully investigate its nature, and no immediate practical advantage accrued from his excellent analysis. About the same time, Sertürner was engaged in a similar investigation, the results of which, very analogous to those obtained by Seguin, were published in a German journal, without, however, attracting general attention. In this state the subject remained until 1817, when Sertürner announced the existence of a saline compound in opium, consisting of a peculiar alkaline principle united with a peculiar acid, and clearly demonstrated the precise nature of a substance which, though discovered both by Seguin and himself, had been hitherto but vaguely known. To the alkaloid, in which he correctly conceived the narcotic powers of opium to reside, he gave the name of *morphium*, which has been since changed to *morphine*, in order to render it conformable with the titles of the other alkaloids. The acid he called *meconic*, a term derived from the Greek name of the poppy. The correctness of the statements of Sertürner was confirmed by Robiquet, who also satisfactorily demonstrated that the substance obtained by Derosne and called by him the *salt of opium* was a principle altogether distinct from morphine, though supposed to possess considerable influence over the system. In the belief in its narcotic powers, Robiquet denominated it *narcotine*, a title which it still retains. A number of other alkaloids have since been discovered in opium, although most of these are in very limited amount, and the existence of some is not quite definitely established. According to the views of its constitution at present accepted, it contains: 1. *Morphine*, $C_{17}H_{19}NO_3$; 2. *Codeine*, $C_{18}H_{21}NO_3$; 3. *Thebaine*, $C_{19}H_{21}NO_3$; 4. *Papaverine*, $C_{20}H_{21}NO_4$; 5. *Meconidine*, $C_{21}H_{23}NO_4$; 6. *Codamine*, $C_{20}H_{25}NO_4$; 7. *Laudanidine*, $C_{20}H_{25}NO_4$; 8. *Laudanine*, $C_{20}H_{25}NO_4$; 9. *Laudanosine*, $C_{21}H_{27}NO_4$; 10. *Lanthopine*, $C_{23}H_{25}NO_4$; 11. *Protopine*, $C_{20}H_{19}NO_5$; 12. *Cryptopine*, $C_{21}H_{23}NO_5$; 13. *Rhæadine*, $C_{21}H_{21}NO_5$; 14. *Narcotine*, $C_{22}H_{23}NO_7$; 15. *Oxynarcotine*, $C_{22}H_{23}NO_8$; 16. *Narceine*, $C_{23}H_{25}NO_8$; 17. *Pseudomorphine*, $C_{34}H_{36}N_2O_8$; 18. *Gnoscopine*, $C_{22}H_{23}NO_7$; 19. *Xanthaline*, $C_{37}H_{36}N_2O_8$; 20. *Tritopine*, $C_{43}H_{54}N_2O_7$; 21. *Hydrocotarnine*, $C_{12}H_{15}NO_3$. In addition to the above list, *Deuteropine*, *Opianine*, *Papaverosine*, and *Porphyraxine* are possible alkaloids that have been announced, but not sufficiently established as yet. Still others, like *Apomorphine* (see p. 159), can be produced from those existing in the opium. At least two acids occur in opium combined with these bases,—*meconic acid*, $C_7H_4O_7$, and *lactic acid*, $C_3H_5O_3$. This latter, supposed by T. and

H. Smith to be a peculiar variety of lactic acid, and named by them *thebolactic acid*, was ascertained by Stenhouse to be the ordinary variety. Sulphuric acid is found in the ash along with the bases calcium, magnesium, and potassium. Opium also contains *mucilage*, *pectic matter*, and a *glucose sugar*. The wax gathered from the refuse of opium yielded Hesse *cerotyl palmitate* and *cerotate*. Three neutral principles have, moreover, been extracted from opium,—*meconin* (*opianyl*), $C_{10}H_{10}O_4$, *meconoisin*, $C_8H_{10}O_2$, and *opionin*, which, according to Hesse, is contained in small quantities in Smyrna opium. The first of these forms prisms which fuse under water at $77^\circ C.$, or *per se* at $110^\circ C.$, and boil at $155^\circ C.$; the second melts at $88^\circ C.$, and the third at $227^\circ C.$ None of these neutral principles contain nitrogen. All the organic bases of opium polarize to the left. (Bouchardat and Boudet, *J. P. C.*, 3e sér., xxiii. 294.)¹

Of the principles above mentioned, *morphine* is by far the most important. It is generally admitted to exist in opium united with meconic acid in the state of meconate, and to a certain extent also as a sulphate, although A. R. L. Dohme (*A. J. P.*, 1891, p. 168) believes that the results of a dialysis of opium show that the morphine is combined with sulphuric acid alone.²

CODAMINE.—*Codamina*, $C_{20}H_{25}N_2O_4$, is isomeric with *laudanine*, but is readily distinguished from it by the effect of ferric chloride and nitric acid, both of which color it deep green. According to Allen, codamine also gives a dark green coloration with sulphuric acid and, in the presence of a minute quantity of ferric chloride, a greenish blue. It is in anhydrous crystals. It can be purified by taking advantage of the feeble solubility of its iodide. Having decomposed this salt by ammonia, dissolve the precipitate in ether, wash the ethereal solution with solution of sodium bicarbonate, then filter through animal charcoal. By evaporation the liquid deposits the alkaloid in beautiful colorless crystals. Codamine crystallizes also from petroleum benzin; but thus obtained it melts at $126^\circ C.$ ($258.8^\circ F.$), while that procured through ether melts at about $120^\circ C.$ ($248^\circ F.$). The acid iodide, tartrate, and oxalate are crystallizable.

CODEINE.—*Codeina*, $C_{18}H_{21}NO_3$ (or $C_{17}H_{17}NO(OH).OCH_3$), was discovered in 1832 by Robiquet in morphine hydrochloride prepared according to the process of Gregory, and was prepared synthetically by Grimaux by the action of methyl iodide and sodium hydroxide upon morphine, thus proving its chemical char-

¹ Lahens of Toulouse, found glucose in a tincture of poppy capsules, and in all the commercial varieties of opium, in proportions varying from 3 to 14.5 per cent. Its presence in opium is therefore not a proof of sophistication. (*J. P. C.*, Oct. 1854, p. 265.)

² Proportionate quantity of the more important constituents of Opium.—Smith of Edinburgh obtained from 100 parts of fine opium 10 parts of morphine, 6 of narcotine, 0.15 of thebaine, 1 of papaverine, 0.3 of codeine, 0.02 of narceine, 0.01 of meconin, 4 of meconic acid, and 1.25 of thebolactic acid. (*P. J.*, Oct. 1865, p. 183.)

acter as a morphine methyl-ether (Allen). It exists in opium combined like morphine with meconic acid, and is extracted along with that alkaloid in the preparation of the hydrochloride. (See *Morphina*.) When the solution of the mixed morphine and codeine hydrochlorides is treated with ammonia, the former alkaloid is precipitated, and the codeine, remaining in solution, may be obtained by evaporation and crystallization. It may be purified by treating the crystals with hot ether, which dissolves them, and yields the codeine in colorless crystals by spontaneous evaporation. This alkaloid and its phosphate and sulphate are now official. (See *Codeina*.) For a paper on the determination of codeine in opium by Chas. E. Caspari see *Proc. A. Ph. A.*, 1904, 386.

CRYPTOPINE. *Cryptopina*, $C_{21}H_{23}NO_5$.—The discovery of this alkaloid was announced by T. and H. Smith of Edinburgh, in *P. J.*, 1867, p. 595. They obtained it from the weak alcoholic washings of crude morphine after precipitation, by first neutralizing the liquid with diluted sulphuric acid, and then, after recovering the alcohol by distillation, and washing out the still, copiously, with hot water, by precipitating the mixed liquor of the still and the washings by milk of lime in large excess. The liquid is then filtered off, and the pitch-like precipitate, having been thoroughly washed, is boiled with alcohol in large quantity, the solution filtered, and the alcohol distilled off. The pitchy substance which remains in the retort, and which consists mainly of thebaine, is separated from the supernatant aqueous liquid, and heated to ebullition with enough alcohol to dissolve it. The solution, having been put aside, will be found in a day to have set into a mass of crystals, which consist of crystallized thebaine. This mass is now strongly pressed in a cloth, and the residuary cake powdered and dissolved in diluted hydrochloric acid, care being taken that the acid is not in excess. The filtered liquid is evaporated and crystallized, and the process of evaporation and crystallization repeated, so as to separate all the thebaine hydrochloride. If now the mother waters are set aside, the cryptopine hydrochloride will in the course of some weeks crystallize out of them, but mixed with crystallized thebaine hydrochloride; the separation of the two is extremely difficult. But as the crystals of the two alkaloids are very different, those of thebaine being hard and strong, those of cryptopine soft and generally tufted, by careful management, and by repeating the crystallization many times, so as to get rid of most of the thebaine, the cryptopine hydrochloride may be seen forming on the surface of the harder salt in the solution. The mother liquors now being poured off, and allowed to evaporate spontaneously, the whole at length sets into a soft mass, which, being pressed in a cloth, is found to consist of almost pure cryptopine hydrochloride. To obtain the pure alkaloid, it is precipitated from solution of the hydrochloride by

ammonia, washed, dried, and finally washed with ether or alcohol, which readily dissolves thebaine, but has little effect on cryptopine. It may be obtained in a crystallized state by boiling it with a large quantity of alcohol, which, on cooling, will slowly deposit the alkaloid in crystals. The quantity in opium is extremely small.

Cryptopine is without color or odor, and its salts, though at first bitter to the taste, afterward cause a sense of coolness in the mouth, like that produced by peppermint. It melts at 217°C. , and, on cooling, crystallizes in radiated forms at 171°C. , and, heated to redness, is decomposed, blackening and giving forth aqueous vapors, but without properly subliming. It is insoluble in water and in ether, very sparingly soluble in alcohol, requiring 1265 parts of that liquid when cold to dissolve it. Chloroform dissolves it almost as freely as narcotine. Oil of turpentine and benzene do not appear to dissolve it. It has very strong alkaline powers, and forms crystallizable salts with the acids, which are distinguishable from all the other salts of the opium alkaloids by a strong tendency to gelatinize. If the hydrochloride is dissolved in about 30 parts of hot water, and set aside, instead of crystallizing, it forms a jelly closely resembling that of pure gelatin. From all the constituents of opium, except the stronger alkaloids, morphine, codeine, and thebaine, it is distinguished by its strong alkaline properties, as it neutralizes the strongest acids. From morphine it is distinguished by its very sparing solubility in alcohol, and from codeine and thebaine by its total insolubility in ether. It differs also in the effect of strong sulphuric acid, which produces a blue color with the minutest quantity of cryptopine, a blood red with thebaine, and none with morphine or codeine. The tendency of its salts to gelatinize is another distinguishing property of cryptopine.

DEUTEROPINE, $C_{20}H_{21}NO_5$, according to Allen, is an alleged homologue of protopine and cryptopine. It requires further examination.

GNOSCOPEINE, $C_{22}H_{25}NO_7$, was found by T. and H. Smith in 1878. They first gave to it the formula $C_{24}H_{30}N_2O_{11}$, but in a later communication (*P. J.*, 1893, 1794) gave it the simpler formula which makes it an isomer of narcotine. It is crystallizable, melts at 233°C. (451.4°F.), with partial decomposition, is soluble in chloroform and carbon disulphide, slightly so in benzene, not in ether. The salts have an acid reaction.

HYDROCOTARNINE.—*Hydrocotarnina*, $C_{12}H_{15}NO_5$, is obtained from the mother waters of thebaine, after the removal of cryptopine and protopine with warm petroleum benzin. by precipitation with ammonia; laudanose, which is also precipitated, is removed by treatment of the benzin solution with sodium bicarbonate. The hydrocotarnine is retained in solution by the benzin, from which the laudanose has been deposited on cooling. Hydrochloric acid gas

being made to pass through this solution, hydrocotarnine hydrochloride crystallizes out. This alkaloid, as the name indicates, can be formed from cotarnine, by the action of zinc and hydrochloric acid. It also seems to result from the decomposition of narcotine. (See *Narcotine*.) If the latter be made to boil some time with baryta water, a portion of it will be decomposed, giving rise to a crystallizable substance soluble in ether, which appears to be identical with hydrocotarnine. This alkaloid is very soluble in alcohol, acetone, chloroform, benzin, and ether. It melts at 50°C . (122°F .), and loses at 57°C . the half molecule of water with which it crystallizes. Sulphuric acid dissolves it, coloring it yellow in the cold, and crimson red if heated. Nitric acid colors it yellow; ferric chloride does not affect its color. It has been physiologically studied by Stockman and Dott (*B. M. J.*, Jan. 1891), who find that it produces in the lower animals symptoms similar to those caused by narcotine.

LANTHOPINE.—*Lanthopina*, $\text{C}_{23}\text{H}_{25}\text{NO}_4$, differs from pseudomorphine in not becoming blue with ferric chloride, and in giving, when entirely pure, with sulphuric and nitric acids, colorless solutions. It forms colorless microscopic prisms, which fuse at about 200°C . Its acid oxalate and tartrate are crystallizable. The alkaloid is crystallizable, does not have an alkaline reaction, is sparingly soluble in hot or cold alcohol, ether, or benzene, but readily soluble in chloroform.¹ According to Allen it

¹O. Hesse obtained most of the alkaloids announced by him from the black mother liquors left behind in the process for procuring morphine hydrochloride, first employed by Gregory, and adopted by the British Pharmacopœia. This liquor, diluted with an equal volume of water, was precipitated by an excess of ammonia; the clear liquid was exhausted with ether, and this treated as described in *Ann. Ch. Ph.*, clix. 47. (*P. J.*, Jan. 1872, p. 549.) The method in which these alkaloids were first separated from opium by Hesse was as follows: An aqueous infusion is prepared, and precipitated by sodium hydroxide or lime water in excess. In the liquid, a substance is retained, which may be extracted by ether, and one of the characteristics of which is that it yields with sulphuric acid a purple color. This appears to be the porphyroxine of Merck. This Hesse found to be a mixture of several alkaloids, which he separated in the following manner. The liquid above referred to as containing the coloring matter is well shaken with ether; this, being separated, is acidulated with acetic acid, and the impure acetates are obtained by evaporating off the ether. The residue is mixed gradually with a diluted alkaline solution, and agitated so as to cause the resin which separates to form a mass. After twenty-four hours, the precipitate is separated; the liquid containing the alkaloids is mixed with hydrochloric acid in slight excess, and the alkaloids are then precipitated with ammonia. The whole is now shaken with chloroform, acetic acid is added in slight excess, the chloroform is evaporated, and the residue is neutralized with ammonia. The precipitate produced is reddish-colored, and, though at first resinoid, soon crystallizes. This, which consists of impure lantrophine, is separated by filtration, and the filtered liquid, after twenty-four hours, is mixed with sodium hydroxide, in quantity but little more than necessary to decompose the ammonia salts in solution. It is then shaken repeatedly with ether to separate codeine, which renders it turbid. This alkaloid is separated more readily by ether than the other alkaloids present, meconidine, codamine, laudanine, and another which the author designated by the letter *x*. Ether does not extract the last-mentioned bases from the solution containing fixed alkali until after ammonium chloride has been mixed with it. When the

is obtained from the mother liquor, left from the preparation of morphine by the Robertson-Gregory process. It is a weak base, and is colored orange red by nitric acid, and pale violet by sulphuric acid, the latter color changing to a dark brown on heating.

LAUDANIDINE, $\text{C}_{20}\text{H}_{25}\text{NO}_4$, was discovered by Hesse in 1894. It closely resembles laudanine.

LAUDANINE.—*Laudanina*, $\text{C}_{20}\text{H}_{25}\text{NO}_4$, as first prepared, is mixed with cryptopine, from which it is separated by dissolving it in acetic acid, and adding a slight excess of diluted solution of sodium hydroxide, by which the cryptopine is entirely precipitated. The liquid being filtered, and treated with ammonium chloride, lets fall the laudanine, which soon assumes the crystalline form. The acetate, with the addition of potassium iodide, gives rise to laudanine hydriodide, from which ammonia separates the base perfectly pure. It crystallizes from its solution in boiling alcohol in transparent granules or hexagonal prisms melting at 166°C . It is lævo-rotatory, tasteless, and poisonous, the hydrochloride resembling strychnine in its effects. It is dissolved at 18°C . (64.4°F .) by 647 parts of ether. Sulphuric acid gives with it characteristic reactions. When pure, at common temperatures it assumes a pale rose color, and at 150°C . (302°F .) a reddish violet. When ferric oxide is added, it exhibits the same changes, but with much greater intensity. Laudanine is an energetic base, and with potassium hydroxide forms a crystallizable compound. Its salts, except the neutral sulphate, oxalate, and tartrate, are crystallizable.

LAUDANOSINE.—*Laudanosina*, $\text{C}_{21}\text{H}_{27}\text{NO}_4$, exists in the mother waters of thebaine, with cryptopine and protopine. The thebaine having been precipitated by tartaric acid, the mother water is neutralized by ammonia, and sodium bicarbonate is added. After eight days' rest, a blackish mass separates. The limpid liquid with an excess of ammonia yields a copious precipitate, which, agitated with heated petroleum benzin, gives to that liquid a mixture of several alkaloids. The benzin solution, upon cooling to 40°C . (104°F .), deposits the cryptopine and protopine. On agitation anew with heated sodium bicarbonate and subsequent complete refrigeration, the laudanose crystallizes. It is entirely purified by ether, which dissolves it abundantly, and its hydriodide is but slightly soluble in water. It is itself insoluble in water and the alkalies, but it is

etheral solution is allowed to evaporate very slowly, laudanine first crystallizes, the other three bases remaining as an almost amorphous mass when the ether has all escaped. But if, before the ether has entirely evaporated, the liquid be mixed with solution of sodium bicarbonate, crystals of *codamine* will be deposited as the ether further evaporates. If the mother liquor, from which the two alkaloids have been separated, is now treated with acetic acid and sodium chloride, *meconidine hydrochloride* is precipitated, the base *x* remaining in solution. The latter is quite separated from meconidine by repeatedly dissolving the hydrochloride in water, shaking it with sodium bicarbonate and ether, and then evaporating off the ether. (*P. J.*, Sept. 1870, p. 205.)

soluble in alcohol, acetone, and chloroform. It melts at 89° C. (192.2° F.), and is decomposed at 110° C. (230° F.). Ferric chloride does not color it. Sulphuric acid gives it a rose color in the cold, and violet when heated. Nitric acid transforms it into a nitro-base. The crystals are anhydrous. It forms crystallizable salts, which are soluble and bitter.

MECONIDINE, $C_{21}H_{23}NO_4$, was discovered by Hesse in 1870. It is brownish yellow, amorphous, alkaline, melts at 58° C. (136.4° F.), and is not stable, the salts also being easily altered. It is easily soluble in alcohol, ether, benzene, chloroform, and acetone. It is dissolved by sulphuric acid with an olive-green color, and by nitric acid with an orange-red.

MORPHINE, $C_{17}H_{19}NO_3 + H_2O$, and its preparations are treated under another head. (See *Morphina*.)

NARCEINE,¹ *Narceina*, $C_{23}H_{29}NO_5$,² discovered by Pelletier in 1832, is in white, silky crystals, inodorous, of a bitter taste, the fusing point of which was given as 145.2° C. (291.6° F.) according to Hesse, and as 92° C. according to Pelletier. E. Merck has shown, however (*Chem. Ztg.*, 1889, p. 525), that the ordinary commercial alkaloid of English manufacture melts between 150° and 160° C., and the pure base at 170° to 171° C. Out of water at 60° C. it crystallizes with 2 molecules of water, which it loses at 100° C., and at 140° C. another molecule of water escapes, leaving in the fused residue a mixture of bases. Soluble in 375 parts of cold and 220 of boiling water, soluble also in alcohol, and insoluble in ether. It forms a bluish compound with iodine, the color of which is destroyed by heat and the alkalis. Besides, according to Stein, the blue color is not produced when there is too much of the iodine present, which then causes a brown color with narceine, the blue color appearing, under such circumstances, only when the excess of iodine is saturated by ammonia. (*J. P. C.*, Janv. 1872, p. 59.) It is rendered blue by the action of mineral acids so far diluted as not to decompose it, but does not, like morphine, become blue by the action of ferric salts, nor red by that of nitric acid. According to P. C. Plugge, if a trace of narceine be covered in a porcelain dish with diluted sulphuric acid, no change will be observable; but if the dish be heated on the water bath, a blue color will be developed as soon as the acid has become sufficiently concentrated; this by prolonged heating will pass to cherry-red. If to this red liquid, after cooling, a trace of nitric acid or of potassium nitrite be added, blue-violet streaks will be produced. (*A. Pharm.*, 1887, p. 425.) It is dissolved by the acids, but was thought not to

neutralize them, and, though at first considered alkaline by Pelletier, was afterwards ranked with indifferent bodies. At present, however, its alkaloidal character is admitted; it unites with sulphuric acid to form a crystallizable sulphate. (*J. P. C.*, Avril, 1864, p. 367.) Dragendorff announced that solution of narceine gives a crystalline precipitate with the double zinc and potassium iodide. This reaction may be employed with iodine as a test of narceine. If a solution of this salt, with a little iodized water, be added to solutions of narceine, and the mixture then agitated with ether to remove the iodine in excess, a solution containing a very small quantity of narceine will distinctly assume a blue color. The other alkaloids of opium are destitute of this property. (*J. P. C.*, Avril, 1870, p. 346.) Pelletier obtained it in the course of his analysis of opium. Having formed an aqueous extract of opium, he treated it with distilled water, precipitated the morphine by ammonia, concentrated the solution, filtered it, threw down the meconic acid by baryta water, separated the excess of baryta by ammonium carbonate, drove off the excess of the ammoniacal salt by heat, evaporated the liquor to the consistence of syrup, set it aside till a pulpy matter formed containing crystals, separated and expressed this pulpy matter, then treated it with alcohol, and concentrated the alcoholic solution. This, on cooling, deposited crystals of narceine, which were easily purified by repeated solution and crystallization. Meconin, which often crystallizes with it, may be separated by the agency of ether. The discordancy of the statements of physiologists and clinicians concerning the action of narceine can only be explained by the presence of impurities in the specimens used. The pure alkaloid would seem to be very feeble in its influence, Mitchell having taken five grains without any other effect than causing some headache. The narceine of commerce has been used in doses of one-third to three-fourths of a grain (0.021 to 0.048 Gm.) as a mild narcotic, probably acting through contaminating morphine.

NARCOTINE. *Narcotina*, $C_{22}H_{23}NO_7$.—It exists in opium, chiefly, at least, in the free state, and is left behind in considerable quantity when the drug is macerated with water. It is white, tasteless, and inodorous, and crystallizes in silky flexible needles, usually larger than the crystals of morphine, fusible at 176° C. (349° F.), and decomposes at higher temperature with evolution of ammonia. Heated to 220° C., the residue which remains is *hemipinic acid*, $C_{10}H_{10}O_6$, insoluble in cold water, soluble in 400 parts of boiling water, in 100 parts of cold and 24 of boiling alcohol, which deposits it upon cooling, and very soluble in ether. The fixed and volatile oils, and the diluted acids, also dissolve it; and it has been found to be soluble in the volatile oil of turpentine, which, aided by heat, will extract it from opium, and yield it in crystals by evaporation. (*J. P. C.*, 4e

¹ *Asponarceine*, $C_{23}H_{27}NO_5$, a patented derivative, is made by heating narceine with a concentrated alkali hydroxide solution, dissolving the alkaline salt produced, in alcohol, and treating this solution with an alcoholic solution of an acid.

² Freund and Frankforter believe that this formula of Anderson's should be modified to $C_{23}H_{27}NO_5$. (*Ann. Ph. Ch.*, 1893, 20.)

sér., ii. 156.) As it exerts no alkaline reaction upon vegetable colors, and does not prevent the acids from reddening litmus paper, there would appear to be some reason for denying it the rank of an alkaloid. But it unites with some of the acids, forming definite compounds, which may be procured in a separate state; and Robiquet obtained narcotine sulphate and hydrochloride well crystallized. (*J. P. C.*, xvii. 639, and xix. 59.) Hence it is now generally considered as a weak base, and perhaps this view of it is the most convenient. It must be admitted, however, to have a very feeble neutralizing power. With acetic acid it does not appear to form a permanent combination, for, though dissolved by cold acetic acid, it is separated by heating the solution. It is decomposed by long boiling, or by heating with nitric acid, into *cotarnine*, $C_{12}H_{13}NO_3$, and *meconin*, $C_{10}H_{10}O_4$, and by heating with water to $100^\circ C$. in sealed tubes, into *hydrocotarnine*, $C_{12}H_{13}NO_3$, and *opianic acid*, $C_{10}H_{10}O_6$, while, on the other hand, the action of nascent hydrogen (from zinc and hydrochloric acid) converts it into *hydrocotarnine* and *meconin*, and that of oxidizing agents into *cotarnine* and *opianic acid*. It may be distinguished from morphine by its insipidity, by its solubility in ether and insolubility in alkaline solutions, by not affecting vegetable colors, by assuming a yellowish instead of a blood-red color under the action of strong nitric acid, by not decomposing iodic acid, and by not producing a blue color with ferric salts. It is, however, reddened by a mixture of nitric and sulphuric acids. Hence, if to a mixture of it with strong sulphuric acid a small piece of potassium nitrate is added, a deep blood-red color is produced; while morphine, under the same circumstances, yields a brownish or olive green color. It gives a greasy stain to paper when heated upon it over a candle. Distilled with potassium hydroxide, or simply by heating to $250^\circ C$., it yields *trimethylamine*, $N(CH_3)_3$. Heated with strong hydrochloric acid, it loses two groups, CH_3 , and with concentrated hydriodic acid a third, CH_3 , so that the existence of three methyl groups (CH_3) in narcotine have been established. Water extracts narcotine partially from opium, in consequence of the acid which the latter contains, either free or combined with the narcotine. It is usually obtained mixed with morphine in the processes for procuring that principle, and may be separated by the action of ether, which dissolves it without affecting the morphine, and yields it upon evaporation. It may also be obtained by digesting opium in ether, and slowly evaporating the ethereal solution, which deposits crystals of narcotine. It is said that the same result may be obtained by using the oil of turpentine as the menstruum, first heating it with opium, and then evaporating the solution. Another mode of procuring it is to treat opium, exhausted by previous maceration in water, with diluted acetic acid, filter the solution, precipitate by an alkali, wash the pre-

cipitate with water, and purify it by solution in boiling alcohol, from which it crystallizes as the liquid cools. Should it still be impure, the solution in alcohol and crystallization may be repeated. The proportion of narcotine in opium¹ varies extremely in the different varieties, and in different specimens of the same variety. Thus, in Smyrna opium it has been found by different observers, in quantities varying from 1.30 to nearly 11 per cent. Though narcotine itself is tasteless, its salts are very bitter, even more so than those of morphine. (Berzelius.) Their solution reddens litmus, and yields precipitates with the alkalies and infusion of galls.²

Different opinions have been advanced relative to the action of narcotine on the system. Derosne believed it to be the active principle of opium; though upon experimenting with it he obtained effects but little stronger than those produced by an equal dose of opium itself. Others found it possessed different degrees of narcotic properties, and the results of various experiments which led to the conclusion may be seen in former editions of this work. But a more thorough investigation seems to have proved that it cannot be ranked among narcotic medicines. It has been asserted that narcotine is identical with *aconella*, an alkaloid said to have been extracted by the Messrs. Smith of Edinburgh, from aconite, but Groves failed to find *aconella*. (See page 79, U. S. D., 14th edition.) Narcotine acts feebly upon the lower animals as a convulsant. No cases of fatal poisoning from it in man are on record, and 120 grains of it are said to have been taken without producing distinct results. On the other hand, observers have seen profound narcotism caused by much smaller quantities, these results, however, being without much doubt due to impurities in the drug. According to Leubuscher (*D. M. W.*, 1892), it is a feeble sedative to intestinal peristalsis. Many years ago O'Shaughnessy of Calcutta, recommended narcotine as an antiperiodic, in doses of three grains (0.2 Gm.) three times a day, but it has failed to acquire reputation. See an elaborate paper on the pharmacology of narcotine by A. C. Crawford and A. R. L. Dohme, *Proc. A. Ph. A.*, 1902, 472.

¹ For physiological study of the methylamide derivatives of narcotine (*narcotine methylamide*), see V. A. P. A., 142, 1895.

² ANARCOTINE has been described as an alkaloid especially abundant in the India opium. According to Wm. Roberts (*B. M. J.*, ii. 1895), while Smyrna opium containing 8 per cent. of morphine has in it 2 per cent. of anarcotine, Bengal opium contains 4 per cent. of morphine with 6 per cent. of anarcotine. Anarcotine appears, however, to be simply pure narcotine. (*Merck's Jahresber.*, 1896, 101.) It is said to be nearly destitute of active physiological properties. In the experiments of Surveyor (*B. M. J.*, 1896), one drachm of it given subcutaneously to an anesthetized dog produced no sensible effect. The continuous use of it in large doses seemed, however, to affect the nutrition of the dog. It was at one time largely used in India as an antiperiodic on account of its being cheaper than quinine, but has fallen into desuetude because of the present low price of the cinchona alkaloids.

OPIANINE, which has been claimed to have the formula $C_{21}H_{21}NO_7$, is now supposed to be impure narcotine.

OXYNARCOTINE. *Oxynarcotina*, $C_{22}H_{23}NO_8$. This alkaloid accompanies narcotine, from which it can be separated by treating the mixture with dilute sulphuric acid. On neutralizing the solution with the theoretical amount of sodium hydroxide and heating to boiling, a part dissolves. The undissolved residue is the oxynarcotine. It can also be obtained from the mother liquors of narcotine. According to Beckett and Wright, it crystallizes out of alcohol in very fine needles, which are difficultly soluble in boiling water and boiling alcohol, insoluble in other neutral solvents. Heated to 140° or 150° C., it is carbonized. It is oxidized by ferric chloride to *hemipinic acid* and *cotarnine*. (See PART II.) It is a monacid base, and forms crystallizable salts.

PAPAVERINE. *Papaverina*, $C_{20}H_{21}NO_4$.—The discovery of this alkaloid was announced by G. Merck. It is crystallizable in needles, fusing at 147° C. (296.6° F.), insoluble in water, very sparingly soluble in cold alcohol or ether, more soluble in these liquids boiling hot, and deposited by them on cooling. With acids it forms salts, most of which are very sparingly dissolved by water. The hydrochloride crystallizes with extraordinary facility. The alkaloid is readily dissolved by moderately concentrated hydrochloric acid, from which, on the addition of more acid, the hydrochloride separates, assuming the form of an oily layer at the bottom of the vessel, which is readily converted on standing into a mass of acicular crystals. These crystals are very sparingly soluble in cold water. The hydrochloride yields with platonic chloride a yellow precipitate which is insoluble in boiling water or alcohol. By the action of hydrochloric acid at 130° C., however, it is decomposed into methyl chloride and homopyrocatechol. By the action of concentrated nitric acid there is formed, on heating, the nitrate of nitropapaverine, $C_{20}H_{20}(NO)_2NO_4.HNO_3$, which separates in crystals. The nitro-base can be separated in clear yellow flocks by the addition of ammonia. By the action of tin and hydrochloric acid there is formed a tetrahydropapaverine, $C_{20}H_{25}NO_4$. Cold concentrated sulphuric acid does not color it, but on warming a violet color is obtained; an impure papaverine is colored violet, however, with sulphuric acid even in the cold. Papaverine is prepared by precipitating the aqueous infusion of opium with soda, exhausting the precipitate with alcohol, evaporating the tincture to dryness, treating the residue with a dilute acid, filtering, precipitating by ammonia, dissolving the precipitate in hydrochloric acid, mixing sodium acetate with the solution, and treating the resulting precipitate with boiling ether. The ethereal solution deposits the papaverine on cooling. The results obtained by investigators of the physiological action of papaverine seem hopelessly discordant, and any future studies made

should be prefixed by an absolute chemical examination of the alkaloid used. Leubuscher (*D. M. W.*, 1892) asserts that it acts as a sedative to intestinal peristalsis without producing other effects, and is valuable in the *diarrhœa* of children.

Dose, for a two-year-old child, two-fifths of a grain (0.024 Gm.), repeated three or four times a day.

PORPHYROXINE, according to K. L. Dey (*P. J.*, [3], xii. p. 397), is a definite basic substance, always present in Indian opium, but absent from Turkey or Smyrna opium.

PROTOPINE.¹—*Protopina*, $C_{20}H_{19}NO_5$, is an alkaloid which Hesse separated from cryptopine. Both are precipitated as insoluble hydrochlorides by hydrochloric acid in excess; but if the precipitate be dissolved by an excess of oxalic acid, the acid cryptopine oxalate will crystallize, and protopine remain in the mother waters. The liquid is separated, precipitated by ammonia, and agitated with ether, and the ethereal solution is taken up by hydrochloric acid. Protopine hydrochloride being dense and granular, while cryptopine hydrochloride is very light, the two are separated by levigation,—eighty grammes of crude cryptopine furnishing one and a half of protopine. Separated from the hydrochloride by ammonia, protopine constitutes a crystalline powder, insoluble in water, soluble in alcohol and in hot petroleum benzin and acetone, more soluble in chloroform, insoluble in the alkalies generally, but slightly soluble in ammonia. It melts at 202° C. (395.6° F.), undergoing decomposition, and is in anhydrous crystals. Ferric chloride does not color it; nitric acid colors it yellow; sulphuric acid dissolves it, coloring it first yellow, then red, and lastly violet. The alcoholic solution has an alkaline reaction. The salts are neutral and crystallizable.

PSEUDOMORPHINE.—*Pseudomorphina*, $C_{34}H_{36}N_2O_8$, was discovered by Pelletier in 1835, and is said by Hesse to be identical with Polstorff's *oxymorphine*; but, as it exists in small quantities, and was thought to be only an occasional ingredient in opium, little attention has been paid to it. An interesting fact, however, in relation to it, and one of some toxicological importance, is that it possesses two properties considered characteristic of morphine, those, namely, of being reddened by nitric acid and of striking a blue color with ferric salts, and yet it is without any poisonous influence upon the animal economy. (*J. P. C.*, xxi. 575.) Hesse has investigated the subject, with the following results. He found that it accompanies morphine procured by Gregory's method, and may be separated from that alkaloid by adding ammonia in excess to an alcoholic solution containing both. The morphine is precipi-

¹ E. Schmidt (*A. Pharm.*, 231 (1893), 136) states that protopine is identical with *macloyine*, an alkaloid, which had been found by Eykman in *Macaya cordata*, and that it is also found in *Sanguinaria canadensis*, *Stylophorum diphyllum*, *Eschscholtzia californica*, and other plants.

tated, and pseudomorphine, remaining in solution, may be obtained by evaporating the mother liquid. It is tasteless, insoluble in water, alcohol, ether, chloroform, and diluted sulphuric acid, but easily soluble in solution of potassium and sodium hydroxide, and lime, and in alcoholic solution of ammonia, though sparingly in an aqueous solution of ammonia. It does not neutralize hydrochloric acid, dissolves in concentrated sulphuric acid with the production of an olive-green color, in concentrated nitric acid with an intense orange-red, and in solution of ferric chloride with a blue color. At 120° C. (248° F.) it loses two molecules of water of crystallization, and at higher temperatures is decomposed without melting. It forms sparingly soluble salts with sulphuric, nitric, oxalic, and tartaric acids, and a crystalline deposit, very slightly soluble in hydrochloric acid, with solution of corrosive sublimate. (*Chem. News*, 1867, p. 188.) Hesse is of the opinion that pseudomorphine is identical with the oxymorphine prepared by the action of oxidizing agents upon morphine by Schutzenberger.

RHÆADINE, $C_{21}H_{21}NO_6$, discovered by Hesse in 1865, is crystallizable, but not distinctly alkaline. It fuses at 232° C., and can be sublimed at higher temperatures. It is nearly insoluble in ether, alcohol, benzene, chloroform, water, and ammonia. Its solutions in dilute acids acquire an intense purple color on addition of strong hydrochloric or sulphuric acid, due to the formation of a coloring matter. This is destroyed by alkalis and restored by acids, and is so intense that 1 part of rhæadine will color 10,000 parts of water purple-red, 200,000 deep rose-red, and 800,000 distinctly red, although only a portion of the base is converted into coloring matter. The solution then filtered through bone-black shows the presence of a base, *rhæagenine*, isomeric with rhæadine, but fusing at 223° C., and forming a different series of salts. This alkaloid occurs also in *Papaver Rhæas*.

THERBAINE (*Paramorphina*). *Paramorphine*, $C_{19}H_{21}NO_3$ (or $C_{17}H_{15}NO(OCH_3)_2$), was discovered by Pelletier in the precipitate thrown down from an infusion of opium treated with milk of lime. The precipitate being washed with water until the liquid came away colorless, and then treated with alcohol, instead of affording morphine to this solvent, as was anticipated, yielded a new alkaloid, which was obtained separate by evaporating the alcohol, acting on the residue with ether, allowing the ethereal solution to evaporate spontaneously, and then purifying the resulting crystalline mass by dissolving it in an acid, precipitating by ammonia, and recrystallizing by means of alcohol or ether. Pelletier named it paramorphine, from its close analogy in composition with morphine, from which, however, it is quite distinct in properties. The name of *thebaine* was proposed for it by Couërbe, who was disposed to give the credit of its discovery to Thiboumerly, the director of Pelletier's laboratory. It is white, crys-

tallizable, and of an acrid and styptic rather than bitter taste, fusing at 193.4° C. (379.4° F.), and, according to Hesse, confirmed by D. B. Dott, is not sublimable. Other observers state that it sublimes at 135° C. without fusing, and is deposited in minute crystals resembling caffeine. It is scarcely soluble in water, very soluble in alcohol and ether when cold, and still more so when heated, and capable of combining with the acids, with which it forms salts not crystallizable from their aqueous solution. Alkalies precipitate it from its acid solutions, and, unless in very concentrated solution, do not dissolve it when added in excess. It is not, like morphine, reddened by nitric acid, nor does it become blue with solutions of ferric salts. From codeine it differs in never being in large crystals, in not forming crystallizable salts, in being always precipitated from its acid solutions by ammonia, and in not melting in oily drops. From narcotine, which it most resembles, it may be distinguished by its shorter crystals, which lack the pearly appearance of those of narcotine, by its different taste, by its much greater solubility in cold alcohol, of which 10 parts will dissolve 1 of this principle, while narcotine requires 100 parts, and by the action of nitric acid, which converts it into a resin-like matter before dissolving it, while the same acid instantly dissolves narcotine. Diluted sulphuric or hydrochloric acid in excess changes thebaine, according to Hesse, into two isomeric bases, *thebenine* and *thebaïcine*. When heated to 90° C. under pressure with fuming hydrochloric acid, thebaine yields a base having the probable formula $C_{17}H_{15}NO(OH)_2$, and called by its discoverer, W. C. Howard (*Ber. d. Chem. Ges.*, xvii. 527, xix. 1596), *morphothebaine*, to indicate its origin and relation to morphine.

Thebaine salicylate is practically insoluble in water; hence in the assay of opium the German Pharmacopœia directs the addition of sodium salicylate to the aqueous solution, thus removing the thebaine before precipitating the morphine. Magendie and many subsequent observers agree that thebaine is a powerful spinal convulsant, resembling in its action strychnine. Leubuscher affirms that it is an intestinal stimulant. Eulenberg found one-four-hundredth of a grain sensibly active in man, and the reported failures of large amounts to produce distinct effects have probably been due to the alkaloid used being impure. On motor nerves it seems to have a paralyzing influence, though in the mammal, death takes place from tetanus.

TRITOPINE, $C_{22}H_{24}NaO_7$, was discovered in 1890 by Klauer (*A. Pharm.*, 228, p. 419). It resembles morphine and laudanum in being soluble in sodium hydroxide solution, but is precipitated in the form of an oil by a large excess of the reagent. Tritopine crystallizes in characteristic, anhydrous, transparent, needle-like plates, melting at 182° C., easily soluble in chloroform, but only slightly so in ether. With sulphuric acid it behaves like laudanum. It appears to be a diacid base.

*Color Reactions of the more important Opium Bases (Allen, Com. Org. Anal.,
2d ed., vol. iii., Part II, p. 302).*

Alkaloid.	Nitric Acid (sp. gr. 1.42).	Concentrated Sulphuric Acid.			Erdmann's Test (sul- phuric acid with diluted nitric acid).	Fröhde's Re- agent (sulpho- molybdic acid).	Ferric Chloride.
		Alone.	On adding KClO ₃ or HNO ₃ .	With sugar.			
Morphine	Orange-red, turning yellow on heating.	Cold; no color, or faint pink; on heating, vari- able (dirty green to black).	Rose-red, or blood-red.	Purple, changing to deep red.		Fine violet, turning blue or dirty green.	Greenish- blue.
Apomorphine . . .	Blood-red, or reddish- violet.	No color (or vio- let to brown).		No reaction.		Deep green, turning violet.	Rose-pink, changing to violet and black.
Pseudomorphine . .	Orange-red, changing to yellow.	Cold; no color, or olive-green; heated, dingy, green or pur- ple, finally red.		Olive, then dark green, changing to brown.		Violet, chang- ing to blue and green.	Blue.
Codeine	Yellow, not changing to red.	No color; dirty brownish-green on heating.	Blue on warming.	Cherry-red, changing to violet.	Blue on warming.	Dirty green, changing to blue and pale yellow.	No color.
Thebaine	Yellow.	Blood-red, turn- ing orange-yel- low; olive- green on heat- ing.	Same as with sul- phuric acid alone.		Orange-red.	Blood-red, turn- ing orange-yel- low and color- less.	No color.
Papaverine	Yellow.	Cold; little change; on strongly heat- ing, violet blue, afterwards fading slowly.	No change.		Dull purple.	Green (changing to violet blue) becoming blue and yellow.	No color.
Narcotine	Red.	Darkens; chang- ing to orange and brick-red on gently heat- ing.	Carmine- red.	Fine mahog- any-brown.	On warm- ing, pink, changing to orange-red, and violet.	Pink, changing to green, yel- low and orange	No color.
Narceline	Yellow, fad- ing rapidly.	Brown, dissolv- ing to yel- low solution (changing to dark red). If impure, red or blue color.	No change.	Not charac- teristic.	Brown yellow, be- coming mahogany- brown on heating.	Brownish-green, changing to yellow and reddish (yel- low-brown to blue).	

*Table (from Stohmann and Kerl's Chemie, 4th ed., 1888) showing the behavior of
Opium Alkaloids with Reagents.*

	Morphine.	Codeine.	Narcotine.	Thebaine.	Papaverine.	Narceline.
Phosphomolybdic acid.	Pale-yellow floccy precipi- tate, soluble in ammonia with blue color.	Brown volumi- nous precipi- tate only in concentrated solution.	Brownish-yel- low floccy precipitate.	Yellow floccu- lent precipi- tate.	No reaction.	Brownish-yellow precipitate, be- coming resinous in concen- trated solution.
Phosphoantimonic acid.	No reaction.	Dirty-white tur- bidity.	Pale-yellow flocculent precipitate.	White gelat- inous pre- cipitate.	White curdy precipitate.	No reaction.
Potassio-mercuric iodide.	White gelati- nous precipi- tate.	White curdy precipitates.			Yellowish- white pre- cipitate.	White turbidity, soon turning to resinous lumps.
Potassium iodobismuth- ate.		Orange precipitates.			Faint turbidity.	
Platinic chloride.	Yellow curdy precipitate, be- coming crystal- line.	Clear-yellow flocculent precipitates.			White precipi- tate.	Gradually form- ing yellow crys- talline precipi- tate.
Mercuric chloride.	No reaction.	Whitish turbid- ity.	No reaction.	White floccu- lent precipi- tate.	Whitish turbid- ity.	No reaction.
Gold chloride.	Yellowish- brown precipi- tate, turning resinous.	Flesh-colored precipitate.	Pale-yellow flocculent precipitate.	Flesh-colored precipitate.	Pale-yellow flocculent precipitate.	Yellowish-brown precipitate, turning resinous.
Iodine in potassium iodide.		Reddish-brown precipitates with all.				
Tannic acid.	White turbidity in concentrated salt solutions only.		White flocculent precipitates.		Yellowish pre- cipitate.	White turbidity; in concentrated solutions only.

XANTHALINE, $C_{37}H_{36}N_2O_8$, is a base obtained by T. and H. Smith (*P. J.*, 1893, 772) from the acid mother liquors resulting from the crystallization of morphine or codeine hydrochloride, and purification of the product.

MECONIC ACID, $C_7H_4O_7 + 3H_2O$, is in white crystalline scales, of a sour taste followed by bitterness, fusible and volatilizable by heat, soluble in four parts of boiling water, soluble also in cold water and alcohol, with the property of reddening vegetable blues and forming salts. Its compounds with the earths and heavy metallic oxides are generally insoluble in water. Its characteristic properties are that it produces a blood-red color with ferric salts, a green precipitate with a weak solution of ammoniated copper sulphate, and white precipitates, soluble in nitric acid, with lead acetate, silver nitrate, and barium chloride. It is obtained by macerating opium in water, filtering the infusion, and adding a solution of calcium chloride. Calcium meconate and sulphate are precipitated. The precipitate, having been washed with hot water and with alcohol, is treated with diluted hydrochloric acid at $82.2^\circ C.$ ($180^\circ F.$). The calcium meconate is taken up, and, upon the cooling of the liquid, calcium bimeconate is deposited. This is dissolved in warm concentrated hydrochloric acid, which deposits pure meconic acid when it cools. It may be freed from coloring matter by neutralizing it with potassium hydroxide, decomposing the meconate thus obtained by hydrochloric acid, and again crystallizing. When heated, it loses first its water of crystallization, and then at $120^\circ C.$ a molecule of CO_2 , and yields *comenic acid*, $C_8H_4O_5$; this at $260^\circ C.$ or over, loses another molecule of CO_2 , and yields *pyromeconic acid*, $C_8H_4O_6$. By the action of nascent hydrogen (from sodium amalgam) it yields *hydromeconic acid*, $C_7H_{10}O_7$. Meconic acid has little or no action on the system, and is not used separately in medicine; but its natural relation to morphine requires that it should be understood. The three related compounds, meconic acid, comenic acid, and pyromeconic acid, are now considered to be derivatives of the fundamental compound *pyrone*, $CO < \begin{smallmatrix} CH=CH \\ CH=CH \end{smallmatrix} > O$. Thus, from pyrone, $C_5H_4O_2$, are obtained *oxypyrrone* (pyromeconic acid), $C_8H_8O_2(OH)$, and *oxypyrrone-carboxylic* (comenic) *acid*, $C_8H_8O_2(OH)COOH$, and *oxypyrrone dicarboxylic* (meconic) *acid*, $C_8H_6O_2(OH)(COOH)_2$. Pyrone itself is formed when comenic and chelidonic acids are heated to $250^\circ C.$ Most of the pyrone derivatives are converted by the action of ammonia into pyridone and pyridine compounds.

Meconic acid was formerly recognized by the British Pharmacopœia, but was dropped at the late revision. It appears to be nearly free from active physiological properties. Sertürner took 4.5 grains of sodium meconate, and Grape and Loewer 12 grains of the pure acid, without the production of any symptoms,

while, according to Mulder, Pereira, Lange, and others, 20 grains of the acid cause no sensible effect in the dog.

MECONIN, $C_{10}H_{10}O_4$, a neutral principle before referred to, the existence of which was announced in 1832 by Couërbe, is identical with a substance discovered several years previously by Dublanc, Jr., but of which no account was published. It is perfectly white, in the form of acicular crystals, soluble in about 265 parts of cold and 18 of boiling water, very soluble in alcohol, chloroform, and the essential oils, but only sparingly in ether; fusible under water at $77^\circ C.$, *per se* at $110^\circ C.$, sublimable on careful heating, and possessed of a degree of acrimony which favors the supposition that it may not be without action upon the system. It is neither acid nor alkaline, and contains no nitrogen. Meconin is obtained by precipitating the aqueous infusion of opium with ammonia, washing the precipitate with water until the latter nearly ceases to acquire color, mixing the aqueous fluids, evaporating them to the consistence of molasses, setting them aside for two or three weeks, during which a mass of granular crystals is formed, then decanting the liquid, expressing the mass, and drying it with a gentle heat. The meconin may be separated from the mass by treating it with boiling alcohol of 36° Baumé, evaporating so as to obtain crystals, dissolving these in boiling water with animal charcoal, filtering the liquid while hot, and subjecting the crystals formed upon the cooling of the solution to the action of ether, which dissolves the meconin, and yields it in a state of purity by spontaneous evaporation.

MECONIOISIN, $C_8H_{10}O_2$.—This principle was discovered by T. and H. Smith, in 1878, who obtained it from the oil-like liquid containing meconin, which, upon being left to itself for some days, sets into a mass of crystals. These crystals, upon being drained and cautiously washed with cold weak spirit, are to be boiled in a large quantity of water. The filtered liquid gives a crystallization of meconin, and the mother liquor, when concentrated, and upon being set aside for a time, yields beautiful leaf-like crystalline masses of meconioisin, fusing at $88^\circ C.$ ($190.4^\circ F.$). This principle is neutral, and it may be distinguished from meconin by the following test of T. and H. Smith. "When heated with slightly diluted sulphuric acid, and when the evaporation has reached a certain point, meconin produces a beautiful green color. With meconioisin, under the same circumstances, the coloration is deep red, becoming purple." This substance has been found by Stockman and Dott (*B. M. J.*, Jan. 1891) to be a tetanizant.

OPIONIN, as before stated, was found by Hesse in small quantities in Smyrna opium. It forms white needles, which melt at $227^\circ C.$ These are insoluble in water, but dissolve in alkalies, alcohol, and ether.

THEBOLACTIC ACID, which was discovered by T. and H. Smith of Edinburgh, appears to be

a constant ingredient in opium. These chemists were led to search for it by the consideration that the quantity of meconic acid present is insufficient to saturate the whole of the morphine and other bases, which must, therefore, be neutralized by some other acid. They obtained it from the impure mother liquid of morphine, after all the alkaloids had been thrown down by the addition of an alkali, by concentrating the liquors to a thick consistence, adding alcohol largely, filtering, precipitating any basic matter by sulphuric acid, filtering again, carefully neutralizing by milk of lime, distilling to recover the alcohol, and finally evaporating the residuary contents of the still to a syrupy consistence. After standing for about a week, the syrupy liquid will be seen to have set into a crystalline mass of calcium thebolactate. This, being purified by repeated solution and crystallization, and by animal charcoal, is decomposed by adding the equivalent quantity of sulphuric acid, and separating the liberated thebolactic acid by means of alcohol. Stenhouse showed that the new acid had the composition of lactic acid and was identical with the common variety, and his results were confirmed by J. Y. Buchanan. (*Ber. d. Chem. Ges.*, 1870, p. 182.) The ready crystallization of its salts with lime is a characteristic property.

Incompatibles.—The substances which produce precipitates with opium do not all necessarily affect its medicinal virtues, but the *alkalies*, and all vegetable infusions containing *tannic* and *gallic acids*, are incompatible, the former separating and precipitating the active principles, the latter forming with it an insoluble compound.

Morphiometric Assays of Opium.—The proportion of morphine which any particular specimen of opium will furnish may be considered the best test of its value, except that of actual trial upon the system. Good opium should yield not less than 9 per cent. of crystallized morphine when assayed by the official process. The U. S. Pharmacopoeia directs that opium, in its normal, moist condition should contain not less than 9 per cent. of crystallized morphine, and powdered or granulated opium, dried at a heat not exceeding 85° C. (185° F.), should contain not less than 12 nor more than 12.5 per cent. of crystallized morphine when assayed by the official process, which is as follows:

Assay of Opium. U. S. P. (8th Rev.)
“Opium, in any condition to be valued, *ten grammes*; Ammonia Water, *three and one-half cubic centimeters*; Alcohol, Ether, Distilled Water, Lime Water, each, *a sufficient quantity*. Introduce the Opium (which, if fresh, should be in very small pieces, and if dry, in very fine powder) into an Erlenmeyer flask having a capacity of about 300 Cc., add 100 Cc. of distilled water, stopper the flask, and agitate it every ten minutes (or continuously in a mechanical shaker) during three hours. Then pour the contents as evenly as possible upon a

wetted filter having a diameter of 12 Cm., and, when the liquid has drained off, wash the residue with distilled water, carefully dropped upon the edges of the filter and its contents, until 150 Cc. of filtrate have been obtained. Then carefully transfer the moist Opium back to the flask by means of a spatula, add 50 Cc. of distilled water, agitate it thoroughly and repeatedly during fifteen minutes, and return the whole to the filter. When the liquid has drained off, wash the residue, as before, until the second filtrate measures 150 Cc., and finally collect about 20 Cc. more of a third filtrate. Evaporate carefully in a tared dish, first, the second filtrate to a small volume, then add the first filtrate, rinsing the vessels with the third filtrate, and continue the evaporation until the residue weighs 14 Gm. Rotate the concentrated solution about in the dish until the rings of extract are redissolved, pour the liquid into a tared Erlenmeyer flask having a capacity of about 100 Cc., and rinse the dish with a few drops of water at a time until the entire solution, after the rinsings have been added to the flask, weighs 20 Gm. Then add 10 Gm. (or 12.2 Cc.) of alcohol, shake the flask well, add 25 Cc. of ether, and repeat the shaking. Now add the ammonia water from a graduated pipette or burette, stopper the flask with a sound cork, shake it thoroughly during ten minutes, and then set it aside, in a moderately cool place, for at least six hours, or over night.

Remove the stopper carefully, and should any crystals adhere to it, brush them into the flask. Place in a small funnel two rapidly acting filters, of a diameter of 7 Cm., plainly folded, one within the other (the triple fold of the inner filter being laid against the single side of the outer filter), wet them well with ether, and decant the ethereal solution as completely as possible upon the inner filter. Add 10 Cc. of ether to the contents of the flask, rotate it, and again decant the ethereal layer upon the inner filter. Repeat this operation with another portion of 10 Cc. of ether. Then pour the liquid in the flask into the filter, in portions, in such a way as to transfer the greater portion of the crystals to the filter, and, when the liquid has passed through, transfer the remaining crystals to the filter by washing the flask with several portions of water, using not more than 15 Cc. in all. Use a feather or rubber-tipped glass rod to remove the crystals that adhere to the flask. Allow the double filter to drain, then apply water to the crystals, drop by drop, until they are practically free from mother liquor, and afterwards wash them, drop by drop, from a pipette, with alcohol previously saturated with powdered morphine. When this has passed through, displace the remaining alcohol by ether, using about 10 Cc. or more, if necessary. Allow the filter to dry in a moderately warm place, at a temperature not exceeding 60° C. (140° F.) until its weight remains constant, then carefully transfer the crystals to a tared watch-glass and

weigh them. Place the crystals (which are not quite pure) in an Erlenmeyer flask, add lime water (10 Cc. for each 0.1 Gm. of morphine) and shake the flask at intervals during half an hour. Pass the liquid through two counterpoised, rapidly acting, plainly folded filters, one within the other (the triple fold of the inner filter being laid against the single fold of the outer filter), rinse the flask with more lime water and pass the washings through the filter until the filtrate, after acidulating, no longer yields a precipitate with mercuric potassium iodide T.S. Press the filters until nearly dry between bibulous paper and dry them to a constant weight, then weigh the contents, using the outer filter as a counterpoise. Deduct the weight of the insoluble matter on the filter from the weight of the impure morphine previously found. The difference, multiplied by 10, represents the percentage of crystallized morphine contained in the Opium." *U. S.*

The British Pharmacopœia directs that "any suitable variety of opium may be employed as a source of Tincture of Opium and Extract of Opium of the respective official alkaloidal strengths, provided that when dry it contains not less than $7\frac{1}{2}$ per cent. of anhydrous morphine; but, when otherwise used for officially recognized purposes, opium must be of such a strength that when dried and powdered, the powder heated to 212° F. (100° C.) until it ceases to lose moisture, and the product tested by the appended method, such dry powder shall yield not less than $9\frac{1}{2}$ per cent., and not more than $10\frac{1}{2}$ per cent. of anhydrous morphine. Opium yielding when dried more than 10 per cent. of anhydrous morphine may be diluted to that percentage with any opium containing when dry between $7\frac{1}{2}$ and 10 per cent. of anhydrous morphine, or with Milk Sugar." *Br.*

Assay of Opium. Br.—"Opium, dried at 212° F. (100° C.) and in No. 50 powder, 14 grammes; Calcium Hydroxide, freshly prepared, 6 grammes; Ammonium Chloride, 4 grammes; Alcohol (90 per cent.), Ether, Distilled Water, of each a sufficient quantity. Triturate together the Opium, calcium hydroxide, and 40 cubic centimetres of water in a mortar until a uniform mixture results; add 100 cubic centimetres of water and stir occasionally during half an hour. Filter the mixture through a plaited filter, about 10 centimetres in diameter, into a wide-mouthed bottle having a capacity of about 300 cubic centimetres, and marked at exactly 104 cubic centimetres, until the filtrate reaches this mark. To the filtered liquid (representing 10 grammes of opium) add 10 cubic centimetres of alcohol (90 per cent.) and 50 cubic centimetres of ether; shake the mixture; add the ammonium chloride, shake well and frequently during half an hour; set aside for 12 hours for the morphine to separate.¹ Counterbalance two small

filters; place one within the other in a small funnel in such a way that the triple fold of the inner filter shall be superposed upon the single fold of the outer filter; wet them with ether; remove the ethereal layer of the liquid in the bottle as completely as possible by means of a small pipette, transferring the liquid to the filter; rinse the bottle with 20 cubic centimetres of ether, again transferring the ethereal layer, by means of the pipette, to the filter; wash the filter with a total of 10 cubic centimetres of ether, added slowly and in portions. Let the filter dry in the air, and pour upon it the contents of the bottle in portions, in such a way as to transfer the granular crystalline morphine as completely as possible to the filter. When all the liquid has passed through, wash the remainder of the morphine from the bottle with *morphinated water*,² until the whole has been removed. Wash the crystals with *morphinated water* until the washings are free from color; allow the filter to drain, and dry it, first by pressing between sheets of bibulous paper, afterwards at a temperature between 131° and 140° F. (55° and 60° C.), finally at 230° F. (110° C.) for 2 hours. Weigh the crystals in the inner filter, counterbalancing by the outer filter. Take 0.5 gramme of the crystals and titrate with *decinormal volumetric solution of sulphuric acid* until the liquid, after boiling, slightly reddens *blue litmus paper*. 1 cubic centimetre of this *volumetric solution* represents 0.0283 gramme of pure anhydrous morphine. The weight of pure anhydrous morphine indicated by the titration, plus 0.104 gramme (representing the average loss of morphine during the process), should amount in total to 1 gramme, that is to say, to a total of not less than 0.95 gramme and not more than 1.05 grammes, corresponding to about 10 per cent. of anhydrous morphine in the dry powdered opium." *Br.*

The U. S. 1880 and Br. methods of assay are practically identical in principle, belonging to the class of assays known as "lime processes." Experience has proved that the "lime processes" have some objectionable features, depending as they do upon the principle that opium in the presence of lime is treated with a definite quantity of water until the latter has extracted as much as possible of the soluble portions, after which a certain portion of the solution, which is assumed to represent a corresponding fraction of the weight of the opium, is weighed or measured off, the morphine determined in it, and the percentage calculated from the quantity found in this fraction or aliquot part. The "lime processes," in the hands of ordinary operators, "register too low," the assay being applied to a proportion of the opium

is just as effective as twelve hours'. (*P. J.*, 1886, 398.)

²*Morphinated Water.*—"Prepared by digesting pure morphine in chloroform water for seven days at a temperature of 60° F. (15.5° C.), with occasional agitation, so as to obtain a saturated solution of the alkaloid, and filtering from the undissolved morphine." *Br.* 1898.

¹ Braithwaite and Farr state that, after careful experimenting, they find that two hours' maceration

which may or may not be an aliquot part of the whole, but is generally less than it is assumed to be, because no allowance is made for the increase in volume due to the solution of the solid constituents of the opium. The British Pharmacopoeia overcomes this objection by requiring 104 Cc. of liquid to be taken instead of 100 Cc. A. B. Stevens has improved the lime method and it is conceded by many that the crystallized morphine by this process is freer from impurities than that obtained by Squibb's method, and that it takes less time to perform the assay than that required for the U. S. P. (8th Rev.) method.¹ The U. S. P. assay of 1890 was based on the method of E. R. Squibb, which requires the complete exhaustion of the sample of opium of its soluble matter, the concentration of this solution, and the determination of the morphine in it. The morphine is separated in a crystalline form from its combination with its natural acids in the opium solution, by the addition of the ammonia water; the alcohol present serves to hold up the coloring matter, while the ether facilitates the precipitation of the alkaloidal morphine in crystals, pure morphine requiring 4000 parts of ether for its solution. The U. S. P. (8th Rev.) assay is based upon Squibb's method, with the modification of the introduc-

tion of a correction, *i. e.*, the washing of the morphine crystals with lime water and deducting the weight of the impurities. Want of space prevents our giving a critical review of the other methods of assay in use; we append, however, Squibb's revised process for assaying opium (1893); it is based upon Flückiger's, and, although it has the reputation of "registering high," this is probably due to the care and attention to detail, whereby unnecessary loss is avoided.¹ Teschemacher

¹ *Stevens's Improved Method for Assaying Opium.* Take 4 grammes of opium in fine powder and triturate in a mortar with 2 grammes of fresh oxide of lime (not air slaked) and 10 Cc. of water until a uniform mixture results. Add 19 Cc. of water and stir frequently for half an hour. Filter through a dry filter, about 10 Cm. in diameter. Transfer exactly 15 Cc. of the filtrate to a 60 Cc. flask. To this add 4 Cc. of alcohol and 10 Cc. of ether and shake the mixture. Then add 0.5 gramme of ammonium chloride. Shake well and frequently during half an hour. Set aside in a cool place for twelve hours.

Remove the stopper carefully and preserve, with any adhering crystals, for future use. Pour the ethereal layer into a small funnel, the neck of which has been previously closed with a pledget of absorbent cotton. Rinse the flask with 10 Cc. of ether, and when this has passed through, pour the contents of the flask into the funnel. Without trying to remove all of the crystals from the flask, wash the flask and contents of the funnel with water previously saturated with morphine, until the washings are colorless. When the crystals have drained, add a few drops of water to replace the morphinated water. Place the funnel in the flask containing adhering crystals, and with a glass rod drawn out to a curved point, lift the cotton and rinse the crystals into the flask with 12 Cc. of tenth-normal sulphuric acid V.S., using the cotton on the end of the rod to detach any adhering crystals. Place the cotton in the flask, replace the cork and agitate until the crystals are all dissolved. Rinse the cork and funnel with water and titrate the excess of acid with fiftieth-normal potassium hydroxide V.S.

Divide the number of Cc. of fiftieth-normal potassium hydroxide V.S. used by 5 and subtract this number from 12 (the number of Cc. of tenth-normal sulphuric acid V.S. taken), multiply the remainder by 0.03009, and then by 50; this will give the per cent. of morphine obtained; to this add 1.12 for the morphine remaining in the solution, the sum will be the per cent. of morphine contained in the opium.

Note.—The morphine may be estimated gravimetrically as follows: Proceed as above, except that a rapidly acting filter is used in place of the cotton, and the crystals are all transferred from the flask (and those adhering to the cork) to the filter. Wash as above, dry at a temperature not exceeding 60° C. and weigh. The weight of morphine multiplied by 50 will give the per cent. of morphine obtained. To this add 1.12 for the morphine remaining in the solution, the sum will give the percentage of morphine contained in the opium.

¹ *Squibb's Method of Assaying Opium* (revised 1893).—*Sampling.*—Every fifth lump of a case of opium—except the very small lumps, and every tenth lump of these—is separated for sampling. A cone-shaped piece is cut from each of these lumps, the apex to come from near the centre of the lump. As these are cut out, a small narrow strip is cut from the side of the cone, taking about an equal proportion from its whole length, so as to get a proper relation of quantity from the dry exterior to the moist centre. These strips are collected together in a mass, so as to lose but little moisture by drying, and the cones are returned to the lumps. After a little practice the mass of strips from each case of opium will not much exceed 25 to 30 grammes. It is rolled out into a long cylinder, the two ends doubled in to the centre, and rolled out again, this rolling out and folding in being repeated six times. If the opium be very moist and sticky, a gramme of powdered starch is weighed off and used to cover the surfaces of the hands and table used in the rolling, and this starch is afterwards to be taken account of in weighing off the samples. Two portions, each representing 10 grammes of the opium, are then weighed off from the mass. One of these is flattened out into a thin cake, placed on a tared watch glass, and dried until it ceases to lose weight at 100° C. (212° F.), for the determination of moisture. The other is taken for the assay. When powdered opium is to be assayed, two portions of ten grammes each are to be weighed off, one for drying and the subsequent check assay and the other for the first assay. Powdered opium should not lose over 4 per cent. in drying at 100° C. (212° F.).

Maceration.—The 10 grammes of mass are pulled out and broken into thin pieces, and dropped into a flask of 200 Cc. capacity, 100 Cc. of water added, the whole occasionally well shaken and allowed to stand over-night, then again well shaken. When powdered opium is to be assayed, the 10 grammes of powder are well shaken with 100 Cc. of water, and then an hour or two of maceration is sufficient.

Exhaustion.—The well-shaken opium mixture is carefully poured in the centre of a well-wetted, tared filter of strong paper, of 12 Cm., or 4.8 inches diameter, so folded that the lower part of the cone hangs free in the funnel,—that is, folded for a rather more open angle than that of the funnel used. The filtrate is received in a beaker marked at 150 Cc., and the flask and residue are well washed with water until the filtrate reaches the 150 Cc. mark. By means of a spatula the residue is returned to the flask without breaking the filter, 50 Cc. of water are added, the whole is actively shaken for five minutes and is then returned to the filter, being carefully poured into the centre, so that in draining the residue may be of equal thickness on all sides. This second filtrate is received in a second beaker marked at 150 Cc., and the residue is percolated and washed until the filtrate reaches the mark. In both percolations a large part of the water is dropped from a pipette, held at a height of 5 or 6 inches, upon the edges of the filter and the surface of the residue. When finally drained, the filter and residue are pressed between folds of bibulous paper, dried until they cease to lose weight at 100° C. (212° F.), and weighed, the weight to be stated by percentage for insoluble residue.

Evaporation of the solution.—The weaker solution is evaporated first in a tared capsule of 250 Cc. capacity, on a water bath, to about 10 Cc. The stronger solution is then added to this, and the evaporation continued until the whole is reduced to 14 grammes. This is rinsed round the capsule by a rotary motion until all the rings of extract formed during the evaporation are dissolved, and it is then poured into a tared flask of 100 Cc. capacity. The capsule is then rinsed into the flask with three rinsings of about 2 Cc. of water each time, and

and Smith (*Chem. News*, 1888, pp. 93, 103) criticise severely several well known methods of assay, and recommend their own, which does

finally with enough water in addition to make the entire solution in the flask weigh 20 grammes.

Precipitation.—To the 20 grammes of concentrated solution is then added half its weight, or 10 grammes, of alcohol of not less than 91 per cent. (sp. gr. 0.815), and the mixture is well shaken. Then 25 Cc. or 17.5 grammes of ether of not less than 93 per cent. (sp. gr. 0.725) is added, and the mixture again well shaken. To this 3.5 grammes or 3.5 Cc. of water of ammonia of 10 per cent. strength (sp. gr. 0.960) are added, and the mixture is vigorously shaken for ten minutes. Usually within two minutes from the commencement of this shaking out of the morphine, and often within one minute, a sudden change in the sound of the shaken mixture occurs. From a soft, rather oily sound the change is to a sharp rattle, and coincidentally with this change a very large proportion of the morphine crystallizes out in crystals as large as particles of fine sand. At the end of ten minutes' shaking the flask is set aside over-night or for not less than six hours.

Separation and washing.—The ether layer is poured off as closely as possible, and 20 Cc. of fresh ether are added to the contents of the flask and rinsed round without shaking. This is poured off as closely as possible, and 20 Cc. more of fresh ether added, rinsed round, and poured off as before, and this is repeated with a third portion of 20 Cc. of fresh ether. A pair of counterbalanced filters 9 Cm., or 3.6 inches, in diameter, folded at an angle slightly wider than the funnel, and well wetted with ether, then receive the contents of the flask, the upper ether layer being slowly poured in first, so that it may pass through before the paper becomes wetted with the aqueous solution. When the liquid has nearly drained through from the crystals on the filters, those from the flask are washed out on to the filters by repeated portions of water, about 3 Cc. at a time, until all the crystals are upon the filters. Then water is applied, drop by drop, from a pipette held 3 or 4 inches above the funnel, to the edges of the filters, and the surface of the crystals until they are fairly clean and the mother liquor and washings together do not exceed 50 Cc. Then 5 Cc. of a saturated solution of morphine in 91 per cent. alcohol is dropped from a pipette, first upon the crystals on the point of the filter, and then upon the edges of the filters, so as to displace all the aqueous solution and leave them saturated with the alcoholic liquid. Then, before this has time to dry, it is displaced by dropping on, in the same way, 5 Cc. or more of ether. When this has drained through, the filters are closed together upon the crystals in the original folds and pressed between folds of bibulous paper, under weights, for half an hour. The filters are then opened, and when the morphine is spread out upon the inner one they are dried at 60° C. (140° F.) until they cease to lose weight. This is the crude morphine, and if a small portion of it is found to be entirely and quickly soluble in one hundred times (or more) its weight of lime water, the weight of the morphine multiplied by 10 is accepted as the percentage of morphine yielded by the opium.

Correction or control of results.—When the preliminary testing of a small quantity of the precipitate shows that it is not all entirely soluble in lime water, 0.5 gramme is weighed off, put into a graduated cylinder, and 50 Cc. of lime water added by pouring down the side of the inclined cylinder. The contents of the cylinder are then tilted backward and forward without shaking, so as to avoid the formation of froth on the surface, until all that is soluble is dissolved. Whenever there is doubt as to when the solvent action is complete, the agitation is continued until the undissolved particles cease to diminish in size or number. The solution is then filtered through a pair of counterbalanced filters about 7 Cm., or 2.8 inches, in diameter, and the filters and residue are well washed, first with 5 Cc. of lime water and then with 5 Cc. of water, and when drained they are closed up, pressed between folds of bibulous paper, dried until they cease to lose weight at 100° C., and weighed. Then as 0.5 gramme of the crude morphine is to the weight of this residue, so is the weight of all the crude morphine to the total amount of insoluble residue it would have yielded if the whole had been subjected to the action of 100 times its weight of lime water. The weight thus obtained, subtracted from the total weight of crude morphine, gives the net weight of pure morphine; and this multiplied by 10 gives the corrected percentage.

not vary greatly from others in use; indeed, it is difficult to resist the conclusion that the differences in the results arrived at by various operators are largely chargeable to personal error and unfamiliarity with other processes than their own. The U. S. P. (8th Rev.) assay method is unquestionably the most practical and accurate that has yet been devised. (See *Ephem.*, June, 1888, 1113; *A. J. P.*, 1887, 74; Prescott's *Organic Analysis*, 1887, 375; Lyons's *Handbook on Assaying Drugs*, 1899, 201; Allen's *Com. Org. Anal.*, vol. iii. Part II, p. 342.)

For other methods of assay, and comments, see U. S. Dispensatory, 14th edition, 675, and 15th edition, 1072; *A. J. P.*, 1876, 358; 1878, 184; 1879, 369; 1894, 445; 1897, 244; *N. R.*, Feb. 1880, Dec. 1880, 1881, 174; *West. Drug.*, 1885, 231, also 1886, 442; *Am. Drug.*, 1885, 221, also 1886, 203; Dieterich's method modified by Schliekm., *Ph. Era*, 1887, 325, also 1888, 9; assay adopted by U. S. Laboratory in New York, *Ph. Era*, 1887, 151; *B. C. D.*, 1894, 372; *P. J.*, 1897, 542.

Moerk recommended the treatment of the crystallized morphine with lime water; see U. S. P. (8th Rev.) assay. (*Proc. Penn. Pharm. Assoc.*, 1897, 65.) Gordin and Prescott propose a volumetric assay based on the estimation of morphine as periodide, after separation by treatment with benzene, acetone, and lime water. (*M. R.*, 1898, 526.) See also *C. D.*, 1898, 20; *D. C.*, 1902, 161; *Ph. Archiv.*, 1898, 121; 1901; 1902, 81, 87; *Proc. A. Ph. A.*, 1899, 263; 1902, 425; 1904, 369; *P. J.*, 1903, 909; 1904, 719; *Chem. News*, 1903, 286.

Tests of Opium.—It is sometimes highly important to be able to ascertain the presence or absence of opium in any suspected mixture. As meconic acid and morphine have been found only in the products of the poppy, if either or both of them be shown to exist in any substance, very strong evidence will be afforded

The lime water solution of 0.5 gramme of morphine and washings are tinted with 10 drops of solution of phenolphthalein, and oxalic acid decinormal solution is dropped in from a burette until the color is discharged. The amount of oxalic acid required indicates the amount of lime water present in the proportion of 40 Cc. of decinormal oxalic acid to 100 Cc. of lime water. The burette is then refilled to the 0 mark for the saturation of the morphine present, and the oxalic acid is dropped in until neutral litmus paper is just slightly reddened. The quantity of the decinormal oxalic acid required should not be less than 16.4 Cc., which indicates, according to the molecular weight of 305.25 for morphine, a degree of purity equal to 100 per cent., or according to a molecular weight of 303, of 99.4 per cent. These figures and results will, of course, apply only to those assays wherein there are no residues insoluble in lime water. Whenever a correction has to be made, of course the titration applies not to 0.5 gramme of morphine, but to 0.5 gramme less the correction, and then the decinormal solution required will be proportionately less. In general practice, perhaps nineteen times out of twenty the lime water testing will show an insignificant amount of insoluble residue, and then the assay process may well end there, so far as concerns its general practical value and the correction and control of results; and the titration is merely held in reserve for exceptional cases and unusual varieties of opium. (*Ephem.*, vol. iii., p. 1152.)

of the presence of opium. The test should, therefore, be applied in reference to the detection of these two principles. If an aqueous infusion of the substances examined yields a red color with the tincture of ferric chloride, there is presumptive evidence of the presence of meconic acid. Greater certainty may be obtained by the following process. Add in excess to the filtered liquor a solution of lead acetate. If opium be present, there will be a precipitate of lead meconate, and the morphine and lead acetates will remain in solution. The precipitate is then to be suspended in water, and decomposed, either by adding a little diluted sulphuric acid, which forms lead sulphate and leaves the meconic acid in solution, or by passing through it a stream of hydrogen sulphide, removing by filtration the precipitated lead sulphide, and heating the clear liquor, so as to drive off the hydrogen sulphide. With the clear liquor thus obtained, if it contain meconic acid, the tincture of ferric chloride will produce a striking red color, ammoniated copper sulphate a green precipitate, and lead acetate, silver nitrate, and barium chloride, white precipitates soluble in nitric acid. Potassium sulphocyanate, which, according to Wright, is an invariable constituent of saliva (*Simon's Chemistry*, ii. 6), produces a red color with ferric salts, resembling that produced by meconic acid, but, according to Everitt, this color is entirely and at once destroyed by a solution of corrosive sublimate, which has no effect on the red color of iron meconate. (*A. J. P.*, xii. 88.) On the contrary, gold chloride reddens a solution of sulphocyanic acid or a sulphocyanate, but not of meconic acid. Pereira says the acetates also redden ferric salts, but do not afford the results just mentioned with lead acetate and barium chloride. To test for the presence of morphine, the liquid from which the lead meconate has been precipitated, and which may be supposed to contain the morphine and lead acetates, must be freed from the lead by a stream of hydrogen sulphide, and then from the hydrogen sulphide by heat, after which the following reagents may be applied,—viz., 1, nitric acid, which colors the morphine red; 2, iodic acid, which is decomposed by the morphine with the extrication of iodine, which colors the liquid reddish brown, and, if starch is present, unites with it to form a blue compound; 3, solution of ammonia, which, if carefully added, so as not to be in excess, throws down a precipitate of morphine soluble in a great excess of that alkali or of potassium hydroxide; and, 4, tannic acid, which precipitates morphine tannate. If the precipitate thrown down by ammonia affords a deep-red color becoming yellow with nitric acid, and a blue color with ferric chloride, the proofs may be considered complete.¹

¹ Merck has proposed a test of opium, founded on the property, which characterizes porphyroxine, of assuming a red color when heated in diluted hydrochloric acid. The suspected liquid is first care-

Though opium is little injured by time if well kept, yet it does undergo spontaneous change, and Guibourt found less morphine in a specimen which had been in his possession nearly twenty years than it had yielded in its recent state. There was also more coloring matter, due to the darkening by age. (*Ann. Thér.*, 1863, p. 5.)

Among the adulterations of opium, starch has been detected in a specimen examined by J. T. King. The drug was unduly brittle, and evidences of starch were afforded both by the microscope and by iodine. From the size and form of the granules, King inferred that the starch was that of the bean. (*A. J. P.*, Jan. 1869, p. 1.) The probability is that powdered beans were the substance used.

Uses.—Opium is a stimulant narcotic. Taken by a healthy person in moderate dose, it increases the force, fulness, and frequency of the pulse, augments the temperature of the skin, invigorates the muscular system, quickens the senses, animates the spirits, and gives new energy to the intellectual faculties. Its operation, while thus extending to all parts of the system, is directed with peculiar force to the brain, the functions of which it excites sometimes even to intoxication or delirium. In a short time this excitation subsides; a calmness of the corporeal actions, and a delightful placidity of mind, succeed, and the individual, insensible to painful impressions, forgetting all sources of care and anxiety, submits himself to a current of undefined and unconnected but pleasing fancies, and is conscious of no other feeling than that of a quiet and vague enjoyment. At the end of half an hour or an hour from the administration of the narcotic, all consciousness is lost in sleep. The soporific effect, after having continued for eight or ten hours, goes off, and is often succeeded by more or less nausea, headache, tremors, and other symptoms of diminished or irregular nervous action, which soon yield to the recuperative energies of the system, and, unless the dose is frequently repeated, and the powers of nature worn out by over-excitement, no injurious consequences will ultimately result. Such is the obvious operation of opium when moderately taken, but other effects, very important from a remedial point of view, are also experienced. All the secretions, with the exception of that from the skin, are in general either suspended or diminished; the peristaltic motion of the

fully evaporated, a few drops of solution of potassium hydroxide are added, and the mixture agitated with ether. The ethereal solution being filtered off, a slip of unsized paper is to be dipped into it and dried, and the moistening and drying should be repeated several times. The paper thus prepared is to be moistened with diluted hydrochloric acid, and then exposed to the vapor of boiling water. If it become reddened, opium may be inferred to exist in the liquid tested. Heuser states that this test is not applicable to the aqueous solution or extract of opium, because porphyroxine is insoluble in water, but Robertson of Rotterdam, has found it to succeed with the aqueous extract, and infers that the porphyroxine is so combined in opium as to render it in some measure soluble. (*J. P. C.*, 3e sér., xxii.)

bowels is lessened; pain and inordinate muscular contraction, if present, are allayed, and general nervous irritation is composed.

In doses insufficient to produce the full soporific effect, the stimulant influence upon the mental functions continues longer, and the subsequent calming effect is sustained for hours, sleep being not unfrequently prevented, or rendered so light and dreamy that, upon awaking, the patient will scarcely admit that he has slept at all. From large doses the period of excitement and exhilaration is shorter, the soporific and anodyne effects are more intense and of longer duration, and the succeeding symptoms of debility are more obvious and alarming.

By quantities sufficient to destroy life, after a brief excitement, the pulse is reduced in frequency, though not in force, muscular strength is diminished, and feelings of languor and drowsiness supervene, which soon eventuate in a deep apoplectic sleep. A stertorous respiration, a dark suffusion of the countenance, a full, slow, and laboring pulse, an almost total insensibility to external impressions, and, when a moment of consciousness is obtained by violent agitation or irritating applications, a confused state of intellect, and an irresistible disposition to sink back into comatose sleep, are symptoms which, for the first few hours, attend the operation of the poison. The pulse is slow, but is full and strong. In the space of a few hours, varying according to the quantity of the narcotic taken and the powers of the patient's constitution, a condition of debility ensues, and this condition will be hastened in point of time, though it will be more under the control of remedies, if the opium be evacuated from the stomach. Called to an individual laboring under the influence of a fatal dose of opium, at a period from six to twelve hours after it has been swallowed, the practitioner will generally find him with a cool, clammy skin, cold extremities, a pallid countenance, a feeble, thread-like, scarcely perceptible pulse, a slow, interrupted, almost gasping respiration, a torpor little short of absolute death-like insensibility, with narrowly contracted pupils. Death soon follows, unless relief be afforded.

After death from opium there are no characteristic lesions discoverable. The active principles of opium are undoubtedly absorbed, and act directly upon the nerve centres, affecting in man chiefly the cerebrum, but in some of the lower animals the spinal system more profoundly than the brain. The slow, full pulse found early in poisoning is due to an excitement of the pneumogastric centres in the medulla, while the rapidity of the pulse late in the poisoning is probably, in part at least, the result of a paralysis of these centres. The great feebleness of the pulse seems to be partially produced by vasomotor paralysis, partially by exhaustion of the intra-cardiac ganglia. The contraction of the pupil is caused by stimulation of the oculo-motor centres, while the sudden

dilatation which immediately precedes dissolution seems to have its origin in a giving out of these centres. The immediate cause of death is failure of respiration, which is due to a direct action of the poison upon the respiratory centre in the medulla oblongata.

On some individuals opium produces peculiar effects, totally differing from the ordinary results of its operation. In very small quantities it occasionally gives rise to excessive sickness and vomiting, and even spasm of the stomach; in other cases it produces restlessness, headache, and delirium, and we have known it, even in large doses, to occasion obstinate wakefulness. The headache, want of appetite, tremors, etc., which usually follow, in a slight degree, its narcotic operation, are uniformly experienced by some individuals to such an extent as to render the use of the medicine very inconvenient. It is possible that some of these disagreeable effects may arise not from the meconate of morphine contained in the opium, but from some other of its ingredients, and those which do result from the meconate may not be produced by other salts of morphine. It is very commonly believed that narcotine is the most depressant of all the active principles. As water does not dissolve it, aqueous preparations of opium are least likely to cause unpleasant after effects.

An occasional effect of opium, which has not yet been mentioned, is a disagreeable itching or sense of pricking in the skin, sometimes attended with a species of miliary eruption. We have found the effect to result equally from all the official preparations of this narcotic.

The local effects of opium are similar in character to those which follow its general operation. An increased action of the part is first observable, then a diminution of its sensibility and contractility, and the latter effect is more speedy, more intense, and of longer continuance, the larger the quantity applied.

In all parts of the world, opium is habitually employed by many with a view to its exhilarating and anodyne influence. This is particularly the case among the Mohammedans and Hindus, who find in this narcotic the most pleasing substitute for alcoholic drinks, which are interdicted by their religion. In India, Persia, and Turkey it is consumed in immense quantities, and many nations of the East smoke opium as those of the West smoke tobacco. This is not the place to speak of the fearful effects of such a practice upon both the intellectual and the bodily faculties.

The use of opium as a medicine can be clearly traced back to Diagoras, who was nearly contemporary with Hippocrates, and it was probably employed before his time. Its extensive applicability to the cure of disease will be rendered evident by a view of the indications which it is calculated to fulfil. 1. It is excitant in its primary action. In *low or typhoid fevers*, requiring a supporting treatment, it

exalts the action of the arterial and nervous systems, and, in moderate doses frequently repeated, may be employed with advantage in conjunction with other stimulants. 2. It is still true that as a general analgesic opium is the most effectual drug known, although in some forms of *neuralgia*, in *migraine* and other *nervous headaches*, as well as in the fulgurant *pains and crises* of spinal sclerosis, antipyrine, acetphenetidin and other coal tar products, especially in combination with caffeine, are often preferable to it. When the pain is severe the opium should be given in the form of a morphine salt, hypodermically injected. 3. Opium is an important somnifacient, and when the *sleeplessness* is produced by pain is the most useful drug of the class. In ordinary insomnia, trional, sulphonal, hydrated chloral, or other of the modern hypnotics are usually to be preferred. Very frequently, as in *delirium tremens*, the combination of opium with these narcotics is especially effective. 4. Opium acts as an antispasmodic, probably by benumbing the sensitiveness of the peripheral or centric nerve system, and hence is useful in *tetanus*, *colic*, *gouty spasm of the stomach*, *cholera*, *nephritic* and *hepatic colic*, and in various convulsive affections. 5. It is useful in allaying various irritations, such as produce excessive *cough*, *nausea*, *tenesmus*, *strangury*, etc. In this way it is valuable in various *internal hemorrhages* in combination with more directly acting remedies. 6. It is often very serviceable in checking morbid discharges, as in serous or other forms of *diarrhœa* with very large liquid stools, also in *diabetes*, in which disease, however, it probably acts by influencing the nervous centres. 7. Combined with ipecac, it is often useful as a diaphoretic (see *Pulvis Ipecacuanhæ et Opii*) in *forming colds*, *sub-acute rheumatism*, *grippe*, etc. 8. Opium although naturally producing constipation by arrest of secretion, is often of service in those cases in which the constipation is dependent upon a very severe local irritation from undigested food or other cause. In all cases of mucous inflammation, as in *bronchitis* or *enteritis* in the first stages when there is dryness of the mucous membrane, opium is contra-indicated on account of its tendency to increase the dryness and prevent secretion through which relief to the congestion is naturally produced.

The dose of opium varies enormously according to the circumstances. We have seen an opium habitué take eight grains of morphine at a dose with no sensible effect other than a little restfulness. Children, especially infants, bear the remedy very badly and we have seen one and a half grains of Dover's powder produce an almost fatal poisoning in a child nearly a year old. Disease also greatly influences the dose; in diarrhœas one-fourth of a grain (0.016 Gm.) may suffice. In tetanus, enormous doses are well borne and in acute peritonitis we have seen 75 grains (5 Gm.) given during the 24 hours with advantage to one unaccustomed to

opium. Whenever opium is given in heroic doses it should be administered hypodermically, at least in part, while whatever is given by the mouth should be in a liquid preparation so as to promote rapid absorption, and should be administered in divided doses at short intervals, the patient being closely watched, and the remedy suspended whenever narcosis appears.

Opium may often be administered with great advantage by the rectum. In this way it operates most advantageously in *obstinate vomiting*, *painful nephritic* and *uterine affections*, *strangury* from blisters, and *dysenteric tenesmus*. It may be employed as a suppository, or in the form of enema made with laudanum and a small quantity of viscid liquid, as flaxseed tea, mucilage of gum arabic, or starch prepared with hot water. Absorption takes place more slowly from the rectum than from the stomach, and a one-half larger dose may be given.

Opium was formerly much used as a local anesthetic in collyria, urethral injections, poultices, etc., but it has very little effect and is not comparable at all in its power with the modern local anesthetics. In the form of laudanum it makes an excellent dressing for minor wounds, but probably acts chiefly through the alcohol of the preparation.

Treatment of Opium Poisoning.—The value of potassium permanganate as a chemical antidote to opium seems to be thoroughly established. It acts by oxidizing and so destroying the alkaloid. It is evident that to exert this influence it must be brought in contact with the alkaloid, and all our physiological knowledge goes to show that potassium permanganate is not absorbed as such in the blood, but always undergoes decomposition by the organic fluids or even tissues with which it is brought in contact. Further, the allegation that potassium permanganate given hypodermically is an efficient antidote in opium poisoning does not seem to be sustained by the clinical records. It is, in fact, a chemical antidote to be administered by the mouth. Recent researches have, however, shown that poisonous alkaloids after their absorption are eliminated by the stomach and upper intestines, to be reabsorbed, so that it is important in a case of opium poisoning not to be satisfied with the primary administration of the permanganate, but to continue giving it in small doses until marked abatement of the symptoms is obtained. In the absence of potassium permanganate, tannic acid should be used as the next best antidote. The stomach should be emptied either by the stomach tube or, when this is not attainable, by the more active mechanical emetics, such as mustard flour, zinc sulphate, or copper sulphate, conjoined with ipecac. Emetics are uncertain in their action, but preferable to the stomach tube when opium has been swallowed in substance, as the lumen of the tube may be insufficient to permit the passage of the masses in which the poison is sometimes taken. The operation of

the emetic should be promoted by a very free use of warm drinks, by irritating the fauces with a feather, by keeping the patient in motion, and, if the insusceptibility to the action of the remedy is very great, by dashing cold water upon the head and shoulders. Very frequently, before the practitioner has reached the patient the narcotism will have progressed so far that it is impossible to cause vomiting at once. Owing to the great disturbance of respiration, two poisons are circulating in the blood, namely, opium and accumulated carbon dioxide. By arousing the patient, and forcing him to supplement the disabled involuntary breathing by voluntary efforts, or, in extreme cases, by artificial respiration, the blood may be so far purified that the nervous centres recover sufficiently their sensitiveness to enable the emetic to act. The great cause of death is failure of respiration, the keeping the patient awake, and the procedures already spoken of, are for the purpose of preventing this failure.

Peremptory orders to breathe should be continually shouted in the ear of the patient. Shaking, forcing to walk, and the galvanic brush, or even flagellations, should be made use of to get the rousing effects of action and pain. Atropine, strychnine, and cocaine should always be used by hypodermic injection as respiratory stimulants. The dose of the alkaloids depends upon the amount of the poison swallowed. Of these alkaloids strychnine is probably the most serviceable, but certainly a much better effect is obtained from the combination of the alkaloids than from any one of them alone. One-seventieth to one-fiftieth of a grain of atropine sulphate may be given but should not be incautiously repeated, lest its secondary depressing effect occur; one-thirtieth to one-twentieth of a grain of strychnine sulphate should be given hypodermically and repeated at short intervals *pro re nata*. One-sixth grain of a cocaine salt is often serviceable when the more powerful alkaloids have already been used freely. It should be remembered that these alkaloids have no mysterious or complete antagonism to morphine, that they do good chiefly by their action upon the respiration and that their influence upon the pupil is no proof of antagonism to morphine and no sufficient guide as to the amount of the alkaloid required. They are used especially to act upon the respiration and their effect upon this function is the chief guide to their administration, although their action upon the pupil and circulation should always be considered. No more of the alkaloids should be used than is necessary to bring and sustain the respiration sufficiently near the normal. In the cardiac debility of the advanced stage of opium poisoning, digitalis and strychnine are the chief reliances. Ammonia may sometimes be employed with advantage and alcohol may be used but in very moderate quantities. It is often well to administer the tincture of digitalis hypodermically before the cardiac failure is established. Coffee is a very serviceable remedy

all through opium poisoning. It acts by relieving the stupor and also as a respiratory stimulant. It should be given *ad libitum*, and as strong as it can be made, or the alkaloid caffeine may be used in five-grain doses repeated *pro re nata*. In rare cases bleeding, in the early stages of the poisoning, when evidences of brain congestion have been very pronounced, has been of distinct advantage. When other measures fail, forced artificial respiration should always be resorted to, to be kept up until the heart beats have certainly ceased.

Dose, from one to two grains (0.065 to 0.13 Gm.).

From granulated opium.—Tinctura Ipecacuanhæ et Opii, *U. S.* (from tincture); Tinctura Opii, *U. S.*; Tinctura Opii Deodorati, *U. S.*; Vinum Opii, *U. S.*

OPIUM DEODORATUM. U. S.

DEODORIZED OPIUM

(ô'pî-ûm dē-ô-dô-ră'tûm)

Opium Denarcotisatum, *U. S.* 1880; Denarcotized Opium.

* "Powdered Opium, five hundred grammes [or 17 ounces av., 279 grains]; Purified Petroleum Benzin, a sufficient quantity. Macerate the Powdered Opium for twenty-four hours in a wide-mouthed, well-closed bottle, with sufficient Purified Petroleum Benzin to completely cover it, shaking occasionally. Decant the liquid as closely as possible and repeat the treatment with Purified Petroleum Benzin. Again decant the liquid and pour the contents of the bottle into a plain filter contained in a glass funnel which should be well covered, drain, and then slowly percolate the residue with Purified Petroleum Benzin until the latter passes without color. Remove the filter containing the Opium from the funnel and expose the powder to the open air, so that it may dry thoroughly. Deodorized Opium should be kept in well-stoppered bottles, and, when assayed by the process given under *Opium*, should be found to yield not less than 12 percent. nor more than 12.5 percent. of crystallized morphine. Opium in coarser powder may be deodorized in the same manner as directed above." *U. S.*

The use of purified petroleum benzin (in place of ether) in the U. S. P. (8th Rev.) process is an improvement. The use of benzin has often been proposed by Ebert and others, but the objection has always been that it was difficult to obtain it of sufficient purity.

This preparation represents the medicinal properties of opium without the presence of the narcotic and odorous principles, which are believed by many physicians to play an important part in the nausea and depression produced in some people by opium.

Dose, one to two grains (0.065 to 1.3 Gm.).

OPIUM GRANULATUM. U. S.

GRANULATED OPIUM

(ō'pī-ŭm grăn-ŭ-lă'tŭm)

"Opium dried at a temperature not exceeding 85° C. (185° F.) and reduced to a coarse (No. 20) powder. Granulated Opium, when assayed by the process given under *Opium*, should yield not less than 12 percent. nor more than 12.5 percent. of crystallized morphine. Granulated Opium of a higher percentage may be brought within these limits by admixture with Granulated Opium of a lower percentage in proper proportions." *U. S.*

This form of opium has been introduced into the U. S. P. (8th Rev.) because on account of its being in coarse powder, it is better fitted for use in making the liquid preparations of opium. (See *Opium*.)

For official preparations of granulated opium see page 910.

OXYMEL. Br.

OXYMEL

(ōx'y-mēl)

Oxymel Simplex; Mel Acetatum, Mellite de Vinaigre, *Fr. Cod.*; Oxymellite simple, Acétomel, *Fr.*; Sauerhoulg, *G.*; Oximiel simple, *Sp.*

"Clarified Honey, liquefied, 40 ounces (Imperial) or 800 grammes; Acetic Acid, 5 fl. ounces (Imp. meas.) or 100 cubic centimetres; Distilled Water, a sufficient quantity. Mix the Clarified Honey with the Acetic Acid and about five fl. ounces (Imp. meas.) or one hundred cubic centimetres of Distilled Water, or sufficient to produce Oxymel having the specific gravity 1.320." *Br.*

This mixture of honey and vinegar forms a pleasant addition to gargles, and is sometimes used as a vehicle of expectorant medicines and to impart flavor to drinks in febrile diseases.

Dose, from one to two fluidrachms (3.75 to 7.5 Ce.).

OXYMEL SCILLÆ. Br.

OXYMEL OF SQUILL

(ōx'y-mēl scīl'læ)

Mellite de Vinaigre Scillitique, Oxymel Scillitique, *Fr. Cod.*; Oxymel Scillæ, *P. G.*; Meerzwiebelhoulg, *G.*; Ossimiele scillitico, *It.*; Oximiel escillitico, *Sp.*

"Squill, bruised, 2½ ounces (Imperial) or 75 grammes; Acetic Acid, 2½ fl. ounces (Imp. meas.) or 75 cubic centimetres; Distilled Water, 8 fl. ounces (Imp. meas.) or 240 cubic centimetres; Clarified Honey, liquefied, a sufficient quantity. Digest the Squill for seven days in a mixture of the Acetic Acid and Distilled Water. Press strongly; filter; Mix the product, which should measure approximately ten fluid ounces (Imp. meas.) or three hundred cubic centimetres, with about twenty-seven fluid ounces (Imp. meas.) or eight hundred and ten cubic centimetres of the Clarified Honey, or sufficient to produce Oxymel of Squill having the specific gravity 1.320." *Br.*

After a long vogue, this preparation fell into such neglect that it was abandoned by the Pharmacopœias. Its reintroduction, however, into the Br. Pharmacopœia indicates that it is still prescribed. It has the virtues of squill, but is in no respect superior to the syrup. It is chiefly used as an expectorant in *chronic catarrh, humoral asthma, whooping cough*, and generally in those states of the pulmonary organs in which the bronchial tubes are loaded with a viscid mucus of difficult expectoration.

Dose, from one-half to one fluidrachm (1.8 to 3.75 Ce.). In large doses it is emetic, and as such is sometimes used in *infantile croup*.

PANCREATINUM. U. S.

PANCREATIN

(păn-crē-ă-tī'nŭm)

"A mixture of the enzymes naturally existing in the pancreas of warm-blooded animals, usually obtained from the fresh pancreas of the hog (*Sus scrofa*, var. *domesticus* Gray), or the ox (*Bos taurus* Linné), and consisting principally of amylopsin, myopsin, trypsin, and steapsin, and proved to be capable, when assayed by the process given below, of converting not less than 25 times its own weight of starch into substances soluble in water." *U. S.*

Pancréatine médicinale, Pancreatina, *Fr. Cod.*; Pancreatina, *Sp.*

The term "pancreatin" has been variously used for many different preparations from the pancreatic gland, and has long been popularly employed for the purpose of distinguishing preparations more or less of the nature of extracts made from the gland. The *pancreatic juice* is an albuminous, transparent liquid, odorless, alkaline, and containing about eight per cent. of organic matter. It is now generally recognized that there are present in it three or, perhaps, four different soluble ferments (enzymes); *trypsin*, whose function it is, when in alkaline solution, to convert albuminous bodies into peptones; *amylopsin*, a diastatic ferment, closely allied to, if it is not identical with, the *ptyalin* of the saliva, and possessed of the power to convert raw or boiled starch into sugar (chiefly maltose); *steapsin*, which has the power of splitting up fats into glyce-

erin and fatty acids; and a *peculiar substance*, not very well known, which acts as a coagulant of milk. Besides its digestive properties the pancreatic juice has the power of emulsifying fats. This emulsifying property is possessed by an alkaline aqueous infusion of the gland, and is therefore present in properly prepared pancreatic extracts. Rachford's experiments appear to prove that pancreatic juice in the presence of an equal quantity of bile and 0.25 per cent. of hydrochloric acid developed its highest efficiency. (*J. Chem. S.*, 1891, 948.)

The pancreatin of the U. S. Pharmacopœia is composed of all these ferments, with more or less extraneous matter. It is officially described as "a cream-colored, amorphous powder, having a faint, peculiar, not unpleasant odor, and a somewhat meat-like taste. Slowly soluble in water, and containing not more than 10 percent. of substances insoluble in this solvent; insoluble in alcohol. Pancreatin digests albuminoids and converts starch into sugar, dextrin, or maltose; it exhibits its peculiar activities in neutral, faintly alkaline, and faintly acid media; more than traces of mineral acids or large amounts of alkalies render it inert. Alkali carbonates exert slightly inhibitory power upon Pancreatin. The digestive power of Pancreatin is injured by contact with pepsin in solution. If 0.28 Gm. of Pancreatin and 1.5 Gm. of sodium bicarbonate be added to 100 Cc. of tepid water contained in a flask, and if 400 Cc. of fresh cows' milk, which has been previously heated to 38° C. (100.4° F.), be then added, and the temperature of the mixture maintained at this point for thirty minutes, the milk should be so completely peptonized that, if a small portion of it be transferred to a test-tube and mixed with some nitric acid, no coagulation should occur." *U. S. R. H. Jones* found commercial pancreatin unable to withstand the U. S. P. 1890 tests, which he stated were too stringent; he suggested the addition of a starch digestion test. (*P. J.*, 1896, 194.) (See official assay of pancreatin.)

The French Codex directs that pancreas gland purified by separating foreign matter is to be cut into small pieces, macerated in chloroform water, then expressed, the liquid filtered and rapidly evaporated at a temperature not exceeding 45° C. Choay (*P. J.*, 1898, 505) criticizes the temperature for evaporation and recommends evaporation *in vacuo* at 38° C. Biernacki (*A. J. P.*, 1892) previously stated that digestive ferments require for their efficient action a temperature little over that of the human body, 39° C. (102.2° F.).

Pancreatin extracts are prepared by different processes by several manufacturers. The process described by R. V. Mattison, based on the method of Scheffer for obtaining pepsin, is as follows: Macerate the cut-up pancreas in water acidulated with hydrochloric acid for forty-eight hours; filter until clear. Add a saturated solution of sodium chloride, and allow to stand until pancreatin rises to the top; skim

this, drain on a muslin filter, wash with a less concentrated solution of salt, and press until nearly dry; then rub up with sugar of milk, dry thoroughly, without heat, and dilute with sugar of milk until ten grains just emulsify two drachms of cod liver oil. The mixed pancreatic enzymes may be extracted from the gland by means of glycerin, and such an extract may be preserved indefinitely. A useful and permanent extract may also be obtained by exhausting the finely divided pancreas with water containing about 2 per cent. of boric acid and 1 per cent. of borax. (Allen, *Com. Org. Anal.*, 2d ed., vol. iv. 354.) As the power of pancreatin cannot be judged of accurately by its physical appearance, it is very important to have some test which will rigidly decide as to its value. If pancreatin be added to fresh milk without an alkali, in the course of a few minutes the liquid acquires the property of curdling abundantly upon boiling, and Wm. Roberts (*Digestive Ferments*, London, 1881) estimates the value of a pancreatin by the number of cubic centimeters of milk which are transformed by one cubic centimeter of the sample at a temperature of 40° C. to the curdling point in five minutes. (See *Liquor Pancreatis*, p. 723.)

A method of determining the value of pancreatin has been made official and is as follows:

Assay of Pancreatin. U. S. P. (8th Rev.) "Pancreatin, *three-tenths of a gramme*; Starch, dry and in fine powder, *seven and one-half grammes*; Distilled Water, Tenth-normal Iodine V.S., each, *a sufficient quantity*. Introduce the starch into a flask, add 120 Cc. of distilled water, and boil until a translucent mixture results. Cool the resulting paste to 40.5° C. (105° F.), and add to it the Pancreatin, previously dissolved in about 10 Cc. of distilled water at 40.5° C. (105° F.). Shake the flask well, maintaining the temperature of the mixture at 40.5° C. (105° F.) during five minutes; at the end of this time all of the starch should be converted into substances soluble in water, and a thin liquid be produced. Mix 2 drops of tenth-normal iodine V.S. with 60 Cc. of distilled water, and add to it 2 drops of the warm converted starch solution; no color should result, or, at most, a wine-red color, showing the presence of dextrin and maltose. The appearance of a blue or purple color indicates the presence of *unconverted starch* and that the Pancreatin is below the standard,—i. e., that of converting not less than 25 times its own weight of starch into substances soluble in water." *U. S.*

Uses.—Pancreatin was first used in medicine on account of its emulsifying properties. Horace Dobell, noticing that consumptives are very likely to have a dislike for fat, conceived the idea that this was due to lack of pancreatic digestion, and administered an emulsion made with the fat of beef stirred in milk with the pancreatic juice of the pig. A little later, pancreatic preparations of cod liver oil were prepared, and still have much vogue. Be-

sides this employment, pancreatin has two distinct uses; first, as a ferment to be administered in dyspepsia; second, as a valuable means for the pre-digestion of food. As pancreatin acts in an alkaline solution and pepsin in an acid one, it would seem *a priori* not probable that pancreatin given by the stomach would be of avail in cases of feeble digestion. Nevertheless, as the experiments of Schweitzer, which have been confirmed by Gross, seem to show, some hours digestion is necessary for the pancreatin to be destroyed by acid solutions. It is therefore probable that when given internally pancreatin may escape from the stomach into the intestines and the combination of pepsin and pancreatin in *dyspepsia* is not unphilosophical. In the pre-digestion of food by pancreatin, five grains of commercial pancreatin of good quality, with twenty grains of sodium bicarbonate, in an ounce of warm water, may be added to a pint of milk, and kept at the temperature of 110° F. for an hour. As the thoroughly peptonized or pre-digested food is very bitter, when the milk is to be given by the mouth it is better to arrest the peptonizing process by boiling the milk after digestion has continued for twenty to thirty minutes, unless the milk can be used at once. For receipts for preparing various peptonized foods, see H. C. Wood's *Therapeutics*. Nutritive enema should be thoroughly pancreatized.

Dose, seven and a half to fifteen grains (0.5 to 1 Gm.).

Off. Prep.—Liquor Pancreatis, Br.

PAPAVERIS CAPSULÆ. Br.

POPPY CAPSULES

(pa-pā've-ris cāp'sū-læ)

"The nearly ripe dried fruits of *Papaver Somniferum*, Linn." Br.

Papaver, *U. S.*, 1870; Capsules de Pavot blanc ou Pavot officinal, *Fr. Cod.*; Fructus Papaveris immaturi, *P. G.*; Unreife Mohnköpfe, Kapseln des Weissen Mohns, Mohnkapseln, Mohnköpfe, *G.*; Papavero, *It.*; Cabezas de amapola, *Sp.*

In England the poppy is cultivated chiefly for its capsules, which are gathered as they ripen, and taken to market enclosed in bags. The Br. Pharmacopœia directs them to be collected before they are quite ripe, as they then contain more of the active milky juice, but, cut at this period, they are apt to lose their juice through the wounded surface, unless carefully kept inverted upon their crown while drying, and even when thus treated, they are, according to the observations of Buchner, less active than the capsules collected after perfect maturity, while they contain more of useless saccharine and mucilaginous matter. (*Buchner's Repert.*, 3 R., viii. 289 and 326.) Meurein states, as the result of his experiments, that the richest are those collected just before the maturity of the seeds, when the capsules have passed from

their glaucous green to a yellowish-green color. (*J. P. C.*, 3e sér., xxiii. 341.) They are occasionally imported, but, as no effect is produced by them which cannot be as well obtained from opium, they are little employed.

Dried *poppy capsules* vary in size from the dimensions of a small egg to those of the fist. They differ also in shape according to the variety of the poppy from which they are procured. On the Continent two sub-varieties of the white poppy are recognized, the *long*, and the *round or depressed*. Of these, according to Aubergier, the long are richest in morphine, and his conclusions are confirmed by Meurein, who also found the largest capsules most efficient. Those commonly found in commerce are spheroidal, flattened below, and surmounted by a crown-like expansion—the persistent stigma—which is marked by numerous diverging rays that rise somewhat above the upper surface and appear to be prolongations of partial septa, or partitions, proceeding along the interior circumference of the capsule from the top to the bottom. In the recent state, the seeds, which are very numerous, adhere to these septa, but in the dried capsule they are loose in its cavity. The capsules of the black poppy are smaller and more globular than those of the white, and contain dark instead of light-colored seeds. There appears to be no essential difference in their properties. Both kinds, when fresh, are glaucous, but when dried are of a dirty-white or purplish-brown color, of a consistence somewhat like that of paper, inodorous, and with little taste, unless long chewed, when they are decidedly bitter. They contain principles, in very small quantities, similar to those of opium, which they yield to water by decoction, and have been employed in France for obtaining morphine.

On the continent of Europe, the poppy is cultivated largely for its seeds, which yield about fifty per cent. of an excellent fixed oil on expression. *Poppy seed oil* is of a pale golden color, liquid at 5.5° C. (42° F.), easily dried, inodorous, and of a pleasant flavor. It is bleached by exposure in thin layers to the sun. (*P. J.*, March, 1874, p. 731.) It belongs to the class of drying oils, ranking after linseed and hemp seed oils in power. For chemical composition, the reader is referred to *Opium*, page 888.

Uses.—Dried poppy heads, though analogous to opium in medicinal properties, are exceedingly feeble. They are nevertheless asserted to have proved fatal, in the form of decoction, to a child. The case, reported by F. L. Winckler, was that of a babe, in the stomach of which he found a little morphine, but no meconic acid. (*N. R. Pharm.*, 1867, xvi. 38.) They are sometimes employed in decoction, as an external emollient and anodyne application, and, in emulsion, syrup, or extract, are used internally, in Europe, to calm irritation, promote rest, and produce generally the narcotic effects of opium.

PARAFFINUM. U. S. (Br.)

PARAFFIN

(pär-af-fi'nūm)

"A mixture of solid hydrocarbons, chiefly of the methane series; usually obtained by chilling and pressing the distillates from petroleum having high boiling points, and purifying the solid press cake so obtained." *U. S.* "A mixture of several of the harder members of the paraffin series of hydrocarbons; usually obtained by distillation from shale, separation of the liquid oils by refrigeration, and purification of the solid product." *Br.*

Paraffinum Durum, Br., Hard Paraffin; Paraffin Wax, Solid Paraffin; Paraffine, Fr. Cod.; Paraffinum solidum, P. G.; Festes Paraffin, Gereinigtes Erdwachs, G.; Paraffina, Sp.

The name paraffin, often spelled *paraffine*, was originally bestowed by Baron von Reichenbach upon a waxy substance obtained through the destructive distillation of wood. He derived it from *parum affinis*, and thus intended to indicate its very neutral character. The name is now popularly applied to a solid white diaphanous substance, resembling white wax, which is procured from petroleum or bituminous shales by distillation, or from ozokerite by purification. (See *Ozokerite, Ceresin*, in PART II.) In the manufacture from petroleum, as carried out in the United States, the residuum from the distillation of crude petroleum for illuminating oil is taken. This is redistilled from what are called "tar stills," in which the distillation is pushed until only coke remains. The paraffin oil distillate obtained in this way is treated with from 4 to 5 per cent. of sulphuric acid, washed, and treated with caustic soda, the mixture being kept liquid by the aid of steam coils. After settling, the paraffin oil goes to the "chill-rooms," where, by the aid of the ammonia refrigerating machines and the circulation of cooled brine, the whole mass is brought to a semi-solid condition. This is subjected to powerful pressure, and the refined heavy oil which drains off is collected as lubricating oil. Its specific gravity should be about 32° B. The press cake may be broken up, melted, and allowed to solidify, and then submitted to still greater pressure at a higher temperature (70° F.) than before, when the product is known as "refined wax." To convert it into block paraffin it must be washed with petroleum benzine, pressed, melted, and filtered through bone black or other medium, when it solidifies in a hard, translucent, colorless block.

Properties.—Paraffin, in its pure condition, is a white, waxy, inodorous, tasteless substance, harder than tallow, softer than wax, with a specific gravity of 0.890. Its melting point is variable, depending somewhat upon its origin. It ranges between 43° and 65° C. (109° and 151° F.). An ultimate analysis yields, on the average, carbon 85 per cent. and hydrogen 15 per cent. It is insoluble in water,

is indifferent to the most powerful acids, alkalis, and chlorine, and can be distilled unchanged with strong oil of vitriol. Warm alcohol, ether, oil of turpentine, olive oil, benzene, chloroform, and carbon disulphide dissolve it readily. It can be mixed in all proportions with wax, stearin, palmitin, and resin. As stearin is less soluble in benzene than paraffin, Vogel proposes this reaction as a method for detecting the adulteration of paraffin with stearin. (*Joy.*) It is officially described as "a colorless, more or less translucent mass, crystalline when separating from solution; without odor or taste, and slightly greasy to the touch. Specific gravity: from 0.890 to 0.905 at 25° C. (77° F.). Insoluble in water or alcohol; slightly soluble in absolute alcohol; readily soluble in ether, petroleum benzin, benzene, carbon disulphide, volatile oils, and in warm fixed oils. Its alcoholic solution should not redden moistened blue litmus paper. When heated, it melts at from 51.6° to 57.2° C. (125° to 135° F.), and on stronger heating ignites, burning with a luminous flame and depositing carbon, but leaving no permanent residue. If 0.5 Gm. of Paraffin be heated in a dry test-tube with an equal weight of sulphur, the mixture will become black from the separated carbon, with the evolution of hydrogen sulphide gas. Paraffin is not acted upon or colored by concentrated sulphuric acid or nitric acid in the cold. If 0.5 Gm. of Paraffin be heated and 0.1 Gm. of powdered fuchsin added to the fused mass, the latter should not assume a pink or red color (absence of *stearic acid*)." *U. S.* The *Br. Pharm.* describes it as "colorless, semi-transparent, crystalline, inodorous and tasteless, slightly greasy to the touch. Specific gravity 0.82 to 0.94. Insoluble in water, slightly soluble in absolute alcohol, almost entirely soluble in ether. An alcoholic solution should not redden litmus. It melts at 130° to 135° F. (54.4° to 57.2° C.), and burns with a bright flame, leaving no residue." *Br.* The fact that solid paraffin wax is essentially made up of a mixture of hydrocarbons of the series C_nH_{2n+2} was established by Gill and Meusel, who studied the action of bromine upon it. The fact that when paraffin wax is oxidized by concentrated nitric acid or by chromium trioxide mixture we obtain *paraffinic acid*, $C_{24}H_{48}O_2$, and *cerotic acid*, $C_{27}H_{54}O_2$, shows that it is essentially made up of hydrocarbons between $C_{24}H_{50}$ and $C_{27}H_{56}$. For *Soft Paraffin*, or *Paraffinum Molle*, see *Petrolatum*, p. 922.

It would be beyond the scope of this work to give all the uses of this very valuable substance. The largest quantity is consumed in candles. It is said that meat may be preserved by immersing it in melted paraffin. Lemons may also be kept in this way. It is used to saturate paper to make it impervious to moisture, as a lubricator, for adulterating chocolate and candies, in large quantities as a basis for chewing gum, to coat pills, etc. (*A. J. P.*, 1895, 422.)

PARALDEHYDUM. *U. S.*, *Br.*

PARALDEHYDE

(pǎ-răl-de-hỹ'dũm)

$C_6H_{12}O_3 = 131.10$

"A polymer of acetaldehyde [$CH_3.COH = 43.70$]. Paraldehyde should be kept in well-stoppered, dark amber-colored bottles, in a cool place." *U. S.* "Paraldehyde, $C_6H_{12}O_3$, is a product of the polymerization of aldehyde by various acids and salts." *Br.*

Paraldehyde, Elaldehyde, *Fr. Cod.*; Paraldehydum, *P. G.*; Paraldehyd, *G.*; Paraaldehido, *Sp.*

Small quantities of acids like hydrochloric and sulphuric, and of certain salts like zinc chloride, $ZnCl_2$, convert aldehyde at ordinary temperatures into its polymer paraldehyde. Its properties are thus described officially: "A colorless, transparent liquid, having a strong, characteristic, but not unpleasant or pungent odor, and a burning and cooling taste. Specific gravity: 0.990 at 25° C. (77° F.). Soluble in 8 parts of water at 25° C. (77° F.), and in 16.5 parts of boiling water; the cold aqueous solution becomes turbid on being boiled. Paraldehyde is miscible, in all proportions, with alcohol, ether, and fixed or volatile oils. When cooled to near 0° C. (32° F.), Paraldehyde solidifies to a crystalline mass, which becomes liquid again at 10.5° C. (51° F.). It boils at 123° to 125° C. (253.4° to 257° F.), evolving inflammable vapors. Paraldehyde is neutral, or slightly acid to litmus paper. When distilled with a small portion of sulphuric acid, Paraldehyde is converted into acetaldehyde, boiling at about 21° C. (69.8° F.). On warming in a test-tube some silver ammonium nitrate T.S. saturated with Paraldehyde, a silver mirror will form on standing. On heating some Paraldehyde on a water-bath, it should completely volatilize, without leaving any disagreeable odor (absence of impurities derived from fusel oil). One Cc. of Paraldehyde should form, with 10 Cc. of water, a clear solution, free from oily drops (absence of amyl alcohol, etc.), and portions of this solution, when acidulated with nitric acid, should not be affected by silver nitrate T.S. (absence of hydrochloric acid), or barium chloride T.S. (absence of sulphuric acid). A mixture of 8 Cc. of Paraldehyde and 8 Cc. of alcohol with 1 drop of phenolphthalein T.S. should acquire a pink color upon the addition of 0.5 Cc. of normal potassium hydroxide V.S. (limit of free acid)." *U. S.*

The British Pharmacopeia gives the following properties and tests: "Soluble in 10 parts of water at 60° F. (15.5° C.); less soluble in hot water. Miscible, in all proportions, with

alcohol (90 per cent.) and with ether. An aqueous solution should not affect solution of litmus. Specific gravity 0.998. Boiling point 255.2° F. (124° C.). It may be congealed to a clear crystalline mass which melts at about 50° F. (10° C.). It affords no coloration on standing for two hours mixed with solution of potassium hydroxide (absence of aldehyde), and should yield no characteristic reaction with the tests for sulphates or for chlorides." *Br.*

Uses.—Paraldehyde produces sleep in the frog and also in mammals, with complete muscular relaxation and loss of sensibility. The heart is not affected until late in the poisoning, and death results from paralysis of the respiratory centres. Not only the brain but also the whole lower nervous system is influenced by the toxic dose of paraldehyde, which decreases the functional activity of the spinal cord, of the motor and sensory nerve trunks, and even of the muscles. It is eliminated by the urine, to which it imparts its odor, and according to Gordon it increases the excretion of urea. Hénocque states that the intravenous injection of paraldehyde markedly affects the spectrum of oxyhemoglobin, and Quinquand that methemoglobin appears in the blood after fatal poisoning by it. Death is alleged to have been produced by four ounces, but in cases in which eight to nine hundred grains have been taken there have been produced no more serious symptoms than many hours of sleep with general muscular relaxation; Probst reports one instance in which nearly five ounces of paraldehyde taken within sixty hours caused profound coma, marked lividity, vomiting, slight fall of temperature but no pronounced circulatory disturbance, and with recovery by the seventh day. After the long continued use of paraldehyde intractable nasal ulcers, skin eruptions and various evidences of disturbed nutrition have been noted. Paraldehyde is a very useful hypnotic in mild insomnia occurring in *neurasthenia* and as an adjuvant to more powerful drugs in *delirium tremens* and in serious forms of morbid wakefulness not dependent upon pain. It has been found especially useful in *asthma* (*L. L.*, vol. i. 1899). The chief disadvantages connected with its use are its tendency to cause gastric disturbance and its inability to relieve pain. It is best administered in a considerable quantity of cold water.

Dose, one-half to one and a half fluidrachms (1.8 to 5.5 Cc.).

PAREIRA. *U. S.* (*Br.*)

PAREIRA [*Pareira Brava*]

(pǎ-rei'rǎ)

"The dried root of *Chondrodendron tomentosum* Ruiz and Pavon (*Fam. Menispermaceæ*)." *U. S.* "The dried root of *Chondrodendron tomentosum*, Ruiz and Pavon." *Br.*

Pareira Radix, Br., Pareira Root; Pareira Brava, Fr., G.

Under the name of Pareira Brava there are three distinct drugs met with in our market. Of these the rarest is the product of the *Cissampelos Pareira*, L. Allen and Hanburys obtained from Jamaica a considerable quantity of this drug, the bulk of it composed of stems, which are described as being cylindrical, varying from the thickness of a quill to that of the forefinger, with a light brown bark. The roots which we have met in American commerce are rarely more than three-fourths of an inch in diameter, are much contorted, and irregularly cylindrical, with a dark brown exterior, which is longitudinally much wrinkled or furrowed. On section they are seen to be composed of a thick corky bark enclosing a woody cylinder consisting of a number (10 to 20) of convergent vascular bundles separated by wedge shaped, very porous, medullary rays. There are no concentric layers of wood. The color is a light yellowish fawn tint, the taste a pure bitter. This is the Pareira Brava of the Br. Pharmacopœia of 1870, the present Br. Pharmacopœia agreeing with the U. S. Pharmacopœia in recognizing the root of *Chondrodendron tomentosum*.¹

The ordinary pareira brava of our markets is that which was exhibited at Philadelphia in the Centennial Exhibition of 1876 by the Brazilian government as the product of *Cissampelos Pareira*, but which is now recognized as being obtained from *Chondrodendron tomentosum*. It consists of great pieces of roots, some of them four inches in diameter and three feet long. They are irregularly cylindrical, often somewhat four sided, with a thin, brownish, closely adherent bark, often grayish in color, and not so closely wrinkled as in some specimens.

On section, the root is seen to consist of from three to nine concentric or excentric rings of growth of a breadth of from one-eighth to one-third of an inch. There is not a distinct continuous series of medullary rays, but each zone is composed of wedge shaped masses, formed of divergent lines of dense woody tissue arched exteriorly over the porous parenchyma. The stems have a similar structure, but with an obvious pith. This is the Pareira Brava of the present U. S. Pharm., which describes it as follows. "Subcylindrical, knotty, and somewhat tortuous, cut into pieces of various lengths, 1 to 6 Cm. in diameter; externally blackish-brown, with transverse ridges and fissures and longitudinal furrows; hard, heavy, and tough; when freshly cut having a waxy lustre, internally yellowish- or brownish-gray, the dried transverse sections exhibiting several inequilaterally concentric circles of interrupted, porous wood-

wedges projecting beyond the markedly retracted intervening tissue of the rather large medullary rays; odor slight; taste bitter." U. S.

Under the name of *Common False Pareira*, Flückiger and Hanbury describe a drug which they state to be a common drug of the Brazilian and English markets. "It consists of a ponderous, woody, tortuous stem and root, occurring in pieces from a few inches to a foot or more in length, and from 1 to 4 inches in thickness, coated with a thin, hard, dark-brown bark. The pieces are cylindrical, four-sided, or more or less flattened,—sometimes even to the extent of becoming ribbon-like. The stem differs from the root externally in being less tortuously and more sparingly marked with transverse ridges and constrictions or cracks, also in the longitudinal furrows being more regular. In transverse section of the stem a well-defined pith will be found to occupy the centre of the first-formed wood, which is a column about $\frac{1}{4}$ of an inch in diameter. This is succeeded by 10 to 15 or more concentric or oftener eccentric zones, 1-10th to 2-10ths of an inch wide, each separated from its neighbor by a layer of parenchyme, the outermost being coated with a true bark. In pieces of true root, the pith is reduced to a mere point." (*Pharmacographia*, p. 29.) This false pareira is not often seen in America. It is stated that in it Wiggers discovered pelosine in 1839. Its botanical source is unknown, but is believed to be a *Menispermum*.¹

Chondrodendron tomentosum, Ruiz and Pavon.—*Cocculus Chondrodendron*, De C.—*Botryopsis platyphylla*, Miers.—This is a climbing, woody vine, which attains often a considerable height, and is remarkable for the size of its leaves. These are about a foot long, broadly ovate or rounded, slightly cordate, with a smooth upper surface, and on the under surface, between the veins, covered with a fine close wool of an ashy hue. The racemose fruits are of the size of large grapes, oval and black. This plant inhabits both Brazil and Peru.

¹ *White Pareira Brava*, the stems and root of *Abuta rufescens*, is described by Flückiger and Hanbury as consisting "of short pieces of a root half an inch to three inches thick, covered with a rough blackish bark, and also of bits of stem having a pale, striated, corky bark cut transversely. The root displays a series of concentric zones of white amylaceous cellular tissue, each marked with narrow wedge-shaped medullary rays of dark porous tissue."

Yellow Pareira Brava, derived from *Abuta amara*, Aublet, highly esteemed in Brazil, is described as consisting "of portions of a hard, woody stem, from one to six inches in diameter, covered with a whitish bark. Internally it is marked by numerous regular concentric zones, is of a bright-yellow color and a bitter taste." It contains berberine.

The root of *Cocculus Caba*, G. P. et Rich., a native of Northern India, Afghanistan, and Arabia, according to Heckel and Schiagenhausen, resembles in appearance and medicinal properties Pareira brava, and contains about 2 per cent. of pelosine with 3 per cent. of a new alkaloid, *sangoline*. This melts at 188° F., and in alcoholic or chloroformic solution rotates the plane of polarized light to the right. It is thrown down by water from its alcoholic solution, and does not give the color reaction that is obtainable from pelosine with sulphuric acid and an oxidizing agent. The root also contains *columbin*, and is used in India as a substitute for hops.

¹ A *West African False Pareira Brava* which has appeared in the London markets is of a chocolate-brown color externally, and of a yellow and brownish-yellow internally. Its woody zones are numerous, and in the larger pieces are arranged excentrically. The root portions have a star of small size in the centre with a variable number of straight rays. The woody wedges are narrow, and their vessels, seen by the microscope, small in diameter. For an elaborate description of the finer microscopical characters of this root as contrasted with that of the *Chondrodendron*, see *P. J.*, 17, 218.

Cissampelos Pareira, Willd., *Sp. Plant.* iv. 861; Woodv., *Med. Bot.* 3d ed., p. 167, t. 65. This is a climbing plant, with numerous slender, shrubby stems, and roundish, entire leaves, indented at the top, covered with soft hair upon their under surface, and supported upon downy footstalks, inserted into the back of the leaf. The flowers are very small, and disposed in racemes, of which those in the female plant are longer than the leaves. The plant is a native of the West Indies and South America. According to Auguste St.-Hilaire, true pareira is obtained from another species of the same genus growing in Brazil, *C. glaberrima*.¹

The British Pharmacopœia Addendum defines *Cissampelos* as "the root of *Cissampelos Pareira*, Linn.," and describes the root as occurring "in slightly compressed undulating pieces, usually having a diameter of about half an inch (twelve millimetres). It is covered with a dark brown bark, easily separable from the underlying fibrous wood, marked with broad shallow longitudinal furrows and fine transverse cracks. A transverse section exhibits a narrow bark surrounding a yellowish-brown woody column consisting of a single ring of from ten to twenty radial woody wedges separated from each other by distinct narrow medullary rays; the vessels of the xylem are large and may be seen with the naked eye. The fracture is fibrous. The root has no odor; it has a very bitter taste." Br. The British Pharmacopœia Addendum contains processes for the decoction and liquid extract of *Cissampelos*, see footnote.²

Properties.—The root imparts its virtues readily to water. Feneuille found in it a soft resin, a yellow bitter principle, a brown substance, a nitrogenous substance, fecula, acid calcium malate, potassium nitrate, and various other salts. He considers the yellow bitter

substance as the active principle. It is soluble in water and alcohol, and precipitated from its solution by tincture of galls. Wiggers announced in 1838 the existence in pareira brava of an alkaloid, for which he proposed the name of *pelosine* or *cissampeline*. Peretti of Rome, and Pelletier afterwards, separated from the root an alkaloid characterized by assuming a beautiful purple color upon contact with strong nitric acid. (*J. P. C.*, xxvi. 162.) In Christison's *Dispensatory* it is stated to be uncrystallizable, insoluble in water, soluble in ether, alcohol, and the acids, and of an intensely bitter and sweetish taste. Flückiger (*P. J.*, 1870, p. 192) found an alkaloid in pareira, and, having thoroughly determined its origin, investigated its properties, and fixed its composition at $C_{15}H_{21}NO_3$, showed its identity with the *bebeerine* of nectandra and the *buxine* of *Buxus sempervirens* obtained by Walz. Ringer and Brooke (*A. J. P.*, 1892, 255) proved that the true chondrodendron root contained a larger quantity of chemical and extractive principles than do the substitutes. (See also Dohme's paper, *D. C.*, 1896, 296.)

Uses.—Pareira is said to be tonic, aperient, and diuretic. It was introduced into European practice so long ago as 1688, and at one time enjoyed considerable reputation as a lithontriptic. It has been recommended in *calculous affections, chronic inflammation and ulceration of the kidneys and bladder, leucorrhœa, dropsy, rheumatism and jaundice*. It is at present chiefly employed for the relief of *chronic inflammations of the urinary passages*, in which it was originally found by Brodie to be very useful. Advantage may very frequently be derived from combining it with belladonna or hyoseyamus. In Brazil it is used in the cure of the *bites of poisonous serpents*,—a vinous infusion of the root being taken internally, while the bruised leaves of the plant are applied to the wound. The dose of pareira in substance is from thirty grains to a drachm (2.0 to 3.9 Gm.). The infusion (1 oz. in 1 pint of boiling water) is useful. A tincture, made by macerating one part of the root in five parts of diluted alcohol, has been given in the dose of a fluidrachm (3.75 Cc.). The aqueous extract may be given in the dose of from ten to thirty grains (0.65 to 2.0 Gm.). There is now an official fluidextract, of which the dose is half a fluidrachm to a fluidrachm (1.8 to 3.75 Cc.).

Dose, thirty to sixty grains (2.0 to 3.9 Gm.).

Off. Prep.—Fluidextractum Pareiræ, U. S. (Br.).

PELLETIERINÆ TANNAS. U. S.

PELLETIERINE TANNAÏTE

(pêl-ê-tî-ê-rî'næ tân'nās)

"A mixture in varying proportions of the tannates of four alkaloids (punicine, iso-punicine, methyl-punicine, and pseudo-punicine),

¹*Pareira Bark.*—Though the root is the official part, the bark is probably possessed of similar virtues. A specimen at the International Exhibition at London in 1862 was in flat pieces, from two to four inches broad, about a line thick, extremely fibrous, so tough that it could be bent without breaking, of a very light dirty-yellowish color, and covered with a light-colored epidermis.

²*Decoctum Cissampeli.* Br. Add. *Decoction of Cissampelos.*—"Cissampelos, thinly sliced, 2½ ounces (Imp. meas.) or 125 grammes; Distilled Water, a sufficient quantity. Boil the Cissampelos with twenty-four fluid ounces (Imp. meas.) in a suitable vessel, for fifteen minutes; strain; if necessary, pour more Distilled Water over the contents of the strainer, so as to produce one pint (Imp. meas.) or one thousand cubic centimetres of the strained Decoction. **Dose**, ½ to 2 fluid ounces." Br. Add.

Extractum Cissampeli Liquidum. Br. Add. *Liquid Extract of Cissampelos.*—"Add to Cissampelos, in No. 40 powder, rather more than an equal bulk of boiling Distilled Water and set aside for twenty-four hours; then pack in a percolator and pass boiling Distilled Water slowly through it until the percolate amounts to about ten times the weight of the Cissampelos or until the latter is exhausted. Ascertain the proportion of extractive matter in the percolate by evaporating a small weighed quantity in a counterpoised dish on a water-bath to a firm consistence, and weighing the product. Then evaporate the bulk of the percolate until the residual liquid contains one-third of its weight of such extractive matter; mix with this residual liquid enough Alcohol (90 per cent.) to produce from three volumes of the evaporated liquid four volumes of the Liquid Extract. Filter, or otherwise clarify, if necessary. **Dose**, ½ to 2 fluid drachms." Br. Add.

obtained from *Punica Granatum* Linné (Fam. *Punicaceæ*). It should be kept in small, well-stoppered, dark amber-colored vials." *U. S.*

Pelletierinum Tannicum, Punicinum Tannicum; Punicine Tannate; Tannate de Pelletierine, *Fr. Cod.*; Gerbsaures Pelletierin, Punicin, *G.*

Preparation.—The bark of *Punica Granatum* is ground, and mixed with milk of lime; the mixture is percolated with water, the percolate shaken with chloroform, and the separated chloroformic liquid which contains in solution the mixed alkaloids, is treated with a weak solution of sulphuric acid; upon the addition of a solution of tannic acid to the neutralized acid solution of the alkaloids, tannates are precipitated; these are washed and dried.

Properties.—The alkaloidal mixture known as Pelletierine Tannate is officially characterized as follows: "A light yellow, odorless, amorphous powder, having an astringent taste, and a weak acid reaction. Soluble in 235 parts of water, 12.6 parts of alcohol, and in 300 parts of ether at 25° C. (77° F.); insoluble in chloroform; soluble in warm diluted acids. Pelletierine Tannate, when dried over sulphuric acid and heated, turns brown at 150° C. (302° F.), softens at about 165° C. (329° F.), and when heated to a higher temperature, decomposes and chars without melting. It leaves no residue on ignition. Ferric chloride T.S. colors aqueous solutions of the salt blue-black. In aqueous solutions of Pelletierine Tannate, soluble lead, mercury, and zinc salts produce white precipitates. Platinic chloride T.S. produces no precipitate. Ammonia water produces a white precipitate, soluble in excess of the precipitant, forming a yellowish-red solution. Aqueous solutions of Pelletierine Tannate immediately reduce silver nitrate T.S., or gold chloride T.S., to metallic silver or gold, respectively, the former as a black precipitate, and the latter as a thin, purplish mirror on the test-tube. Sulphuric acid gives a yellow color; the liquid, on being heated, turns slowly to green, and finally to purple. Nitric acid produces no color. Sulphuric acid containing a trace of selenous acid produces a light bluish-green color, gradually becoming dark green, and developing a pink border." *U. S.*

Uses.—Pelletierine tannate represents the tannicidal properties of *Granatum*, see page 598.

Dose, four grains (0.26 Gm.).

PEPO. *U. S.*, *Br. Add.*

PEPO [Pumpkin Seed]

(πέπο)

"The ripe seed of *Cucurbita Pepo* Linné (Fam. *Cucurbitaceæ*)." *U. S.* "The prepared fresh ripe seeds of cultivated plants of *Cucurbita maxima Duchesne*, also known as *C. Pepo* Linné." *Br. Add.*

Cucurbitæ Semina Preparata, Melon Pumpkin Seeds, *Br. Add.*; Semen Peponis, Semina Cucurbitæ; Semences de Potirons ou de Courge, *Fr.*; Kürbissamen, Kürbiskörner, Graumontsamen, *G.*; Calabaza (Semilla), *Sp.*

The *Cucurbita Pepo*, or common pumpkin, is a plant almost too well known to need description. The seeds are the part used. These are oval, extended into a blunt point at one end, flattish but somewhat swollen in the middle, with a distinct groove on both sides near the edge from one end to the other, when of full size about 9 lines long by 5 or 6 in breadth where broadest, of a light brownish-white color, and a slightly sweetish, somewhat aromatic odor and taste. They consist of a firm brittle coating and a white oily kernel, composed of a short, conical radicle and two flat cotyledons: "Broadly ovate, flat, somewhat biconvex, about 20 Mm. long and 2 Mm. thick; externally whitish or yellowish-white, nearly smooth, with a shallow groove parallel to, and within 1 Mm. of, the margin; seed-coat consisting of a white coriaceous outer layer, and a membranaceous inner layer; embryo whitish, straight, with a conical hypocotyl and two plano-convex cotyledons; slightly odorous when contused; taste bland and oily." *U. S.* The British Pharmacopœia Addendum describes them as follows: "The seeds, which must not be more than one month old, should have been freshly deprived of their yellowish membranous envelope or testa, and of the inner thin brownish rind or tegmen. Anthelmintic. Contain fixed oil, free fatty acids, an aromatic principle, sugar, starch, and the alkaloid *cucurbitine*." *Br. Add.* They contain a fixed oil, consisting of the glycerides of palmitic, myristic, and oleic acids, with some free fatty acid, an aromatic principle, chlorophyll, sugar, starch, and, according to Dörner and Wolkowich, an alkaloid, *cucurbitine*. Deprived of their coating, and exhausted by ether, they yield 30 per cent. of fixed oil. (*Ann. Thér.*, 1862, p. 176.) The researches of Dörner and Wolkowich have not received confirmation, and their alkaloid probably has no existence. Pumpkin seed oil has a sp. gr. at 15° C. of 0.923, and solidifies at -15° C. The cold drawn oil is used for culinary purposes and the lower qualities for burning. The oil dries very slowly. (Lewkowitsch, *Chem. Analysis of Oils*, etc., 2d ed., 1898, 372.) Sieker obtained 30 per cent. of the oil from the seeds; it was reddish-yellow in color, soluble in ether, benzene, and carbon disulphide, but insoluble in alcohol.¹ (*Proc. A. Ph. A.*, 1897, 545.) J. C. Lyons used an ounce of it with success in a case of tapeworm (*A. J. P.*, 1865, 253), but

¹*Oil of Pumpkin Seed.*—Willard Graham endeavored to prepare this oil by expression, but failed to obtain appreciable quantities even under a pressure of 3,000 pounds. By extraction with acetone the ground seed yielded 25 per cent. of oil, clear reddish, limpid, and of agreeable odor and taste. Its sp. gr. at 15° C. was 0.9208; saponification number, 192.5; acid number, 18.9; ether number, 173.6; soluble in all proportions of carbon disulphide, ether, chloroform, and in twenty parts of absolute alcohol, and drying on standing to a tough, yellowish, transparent mass. These properties and constants agree well with a commercial specimen, evidently also obtained by extraction. The latter, however, had a lower acid number, 3.5, while the ether number was somewhat higher, 191.7. (*A. J. P.*, 1901, 352.)

Wolff has found it inert when pure and free from resin, which he prepares by extracting the oil from the powdered seeds by means of petroleum benzin, then treating the remaining powder with ether, chloroform, and alcohol, which yields on evaporation a soft greenish-brown resinous liquid resembling the oleoresin of male fern. Heckel was the first to assert that the active principle is a resin, and in this he has been corroborated by L. Wolff (pamphlet, Phila. 1882), who found the resin to be efficient in doses of fifteen grains (1 Gm.), given in pill, followed in two or three hours by castor oil, and who recommends an alcoholic fluidextract as the best preparation of the drug after the resin. W. E. Miller (*A. J. P.*, 1891, 585) analyzed both the shells and the kernels of pumpkin seed. He also found a resin soluble in alcohol, and a dark reddish fixed oil.

Uses.—It is said that in Italy the seeds of the *Cucurbita maxima*, and in the West Indies those of *C. occidentalis*, have been long used in doses of an ounce and a half as tæniifuges. In the *Dictionary of Materia Medica* by Mérat and De Lens (ii. 493) it is stated that Hoarau had reported that in the Isle of France the seeds of a small variety of pumpkin were used against the tapeworm, and with never-failing success. In the year 1820, Mongeney, a physician of Cuba, published the results of his experience with the flesh of the pumpkin in the same disease. He had discovered the remedy by accident, and found it uniformly successful. He gave to the patient, in the morning, fasting, about three ounces of the fresh pumpkin in the form of a paste, and followed it at the end of an hour by about two ounces of honey, which latter was twice repeated at intervals of an hour. So far as we know, attention was first directed to it in this country by Richard Soule. (*B. M. S. J.*, Oct. 1851.) Since this time the drug has steadily grown in favor, and, properly used, is one of our most efficient and harmless tæniifuges. The patient should be allowed only a light supper of bread and milk, in the morning early should take an ounce and a half of the seeds, a cup of tea or coffee an hour later, but no food, at 10 A. M. a brisk cathartic, and two hours later a substantial meal. We have obtained excellent results from the exhibition of the beaten seeds in the form of an electuary strongly flavored with oil of cinnamon or of gaultheria.

Dose, one to two ounces (31 to 62 Gm.).

PEPSINUM. U. S., Br.

PEPSIN

(pěp-sī'nŭm)

"A proteolytic ferment or enzyme, obtained from the glandular layer of the fresh stomach of the hog (*Sus scrofa*, var. *domesticus* Gray), and proved to be capable, when assayed by the

process given below, of digesting not less than 3000 times its own weight of freshly coagulated and disintegrated egg albumin. If it is desired to use a diluent for reducing Pepsin of a higher digestive power to that required by the Pharmacopœia, sugar of milk should be employed for this purpose." *U. S.* "An enzyme obtained from the mucous lining of the fresh and healthy stomach of the pig, sheep, or calf. Tested as described in the following paragraph [see p. 921], it should dissolve 2500 times its weight of hard-boiled white of eggs." *Br.*

Pepsine, *Fr. Cod.*; Pepsinum, *P. G.*; Pepsin, *G.*; Pepsina, *It.*; Pepsina medicinal, *Sp.*

The U. S. P. 1890 recognized two pepsins, one under the name "Pepsinum," the other "Pepsinum Saccharatum;" the first, or strong pepsin, should digest at least 3000 times its own weight of freshly coagulated albumin; the other is the first product diluted with enough sugar of milk to make it contain 10 per cent. of the strong pepsin. The U. S. P. (8th Rev.) retained the standard of strength of the previous Pharmacopœia for the strong pepsin but modified the assay process, and dropped Saccharated Pepsin.

The British Pharm. 1885 gave the following process for pepsin; it is that proposed by Beale of London. "The stomach of one of these animals [pig, sheep, or calf] recently killed having been cut open and laid on a board with the inner surface upwards, any adhering portions of food, dirt, or other impurity are to be removed and the exposed surface slightly and rapidly washed with a little cold water; the cleansed mucous membrane is then to be scraped with a blunt knife or other suitable instrument, with some pressure, and the viscid pulp thus obtained is to be immediately spread over the surface of glass or glazed earthenware and quickly dried at a temperature not exceeding 100° F. (37.8° C.). The dried residue is to be reduced to powder and preserved in a stoppered bottle." *Br.*

It is now clearly recognized that pepsin owes its digestive action to the presence of a ferment or enzyme, and, although many researches have been made to obtain the pure principle, the nearest approaches have resulted only in producing pepsin of increased digestive power. Pepsins having much greater digestive capacity than that chosen for the U. S. official standard have been manufactured, and the limit has not at this time (1906) been reached, but for all practical purposes the U. S. P. (8th Rev.) pepsin is sufficiently concentrated, and indeed it is usually diluted for internal administration.

Various attempts have been made to concentrate and bring to a convenient form for administration the peptic principle of the gastric juice. It must not be supposed that the substances prepared with this object and sold under the name of pepsin have any claim to be considered as the pure principle. The one

which for a long time was the best in the market was prepared by Boudault¹ by a process which was afterwards essentially adopted in a former French Codex.

The pepsin of the British Pharmacopœia is "a light yellowish-brown or white powder, or pale yellow translucent grains or scales, having a faint odor and a slightly saline taste free from any trace of putrescence, and liable to absorb moisture from the air. Moderately soluble in water, and soluble in about 100 parts of alcohol (90 per cent.)." *Br.*

The U. S. Pharmacopœia recognized pepsin for the first time in the revision of 1880, but it had then been for some years largely used by the American profession. Much of the pepsin thus employed was obtained from Europe, and was of very various quality, most of it being heavily loaded with starch, and some of it containing little or no pepsin. Several American brands have, however, been put upon the market which are superior to Boudault's pepsin. Various processes also have been recommended for obtaining pepsin. The most elaborate and valuable investigation of the subject as yet made is that of E. Scheffer (*A. J. P.*, 1872). He found that various salts, such as sodium and magnesium sulphates and sodium chloride, precipitate pepsin, and, acting upon this discovery, he devised the following processes: Mucous membrane of the pig's stomach, dissected off and finely chopped, is macerated in water acidulated with hydrochloric acid for several days, with frequent stirring. The strained liquid, if not clear, is clarified by allowing it to stand for 24 hours and decanting. Sodium chloride is then thoroughly mixed with it. After several hours the floating pepsin is skimmed from the surface and put on a cotton cloth to drain, and finally submitted to strong pressure to get rid of saline solution. This pepsin, when air dried, is very tough, parchment-like or leathery, varying in color from a dim straw-yellow to a brownish yellow. To make his *saccharated pepsin*, Scheffer added sugar of milk until a powder was obtained of which 10 grains dissolved 120 grains of coagulated albumin. After framing his original process, he increased the strength of saccharated pepsin. *Purified pepsin* he made by redissolving the pepsin in acidulated water and precipitating as before, immersing the product when perfectly dry in pure water for a short time. A half-grain of this dissolved 1500 grains of albumin. (*Ibid.*, p. 784.) The chemical relations of pepsin are so delicate and wide spread that it ought to be given by itself, or in combination only with an insoluble substance, or suspended in inert liquids. For an interesting paper by B. T. Fairchild on Animal Digestive Ferments, reader is referred to *A. J. P.*, Feb. and Mar. 1902.

Since Scheffer's researches were made known, pepsin has been manufactured in the United States in immense quantities, the tendency having been towards strengthening and purifying the product.² Many other substances than sugar of milk have been used to mix with pepsin, as egg and blood albumin, fibrin, and substances which are easily converted into peptones. The process for making most commercial pepsins may be briefly stated as follows. The inner membranous linings of hogs' stomachs are washed, passed through a mincing machine, and the resulting mass digested with diluted hydrochloric acid; the solution is strained or filtered and evaporated *in vacuo* or placed on shallow trays, so that a syrupy liquid which has not been subjected to a higher temperature than 112° F. is produced; this is spread upon glass plates to dry, and the scales which are formed scraped off. The thickness of the scales may be varied by using more or

¹ *Pepsin manufacture.*—In 1904 W. H. Jenkins communicated a detailed description of the method of manufacturing pepsin on a large scale. While pepsin can be prepared from the stomachs of other animals, the mucous membrane of the stomachs of hogs is used because most available. After emptying the stomachs they are carefully washed in cold water, avoiding violent, energetic motion, as a great deal of the pepsin contained is liable to be removed and lost. The outside of the stomachs is trimmed away. The pepsin-containing membrane is chopped into small pieces and placed in a 3 or 4 per cent. aqueous solution of hydrochloric acid, the usual receptacle for this digestion being a large, open headed hoghead, in which it is allowed to remain at a temperature of 104° to 122° F., with frequent stirring, until it undergoes self-digestion. This solution or self-digestion requires from 36 to 48 hours, or sometimes longer. At this point of the process the solution is liable to decomposition, hence careful watching is necessary. An antiseptic condition is produced by passing sulphur dioxide into the solution until it smells strongly of the gas; the gas also bleaches the product. The solution is then allowed to stand and clarify itself by the precipitation of the mucus. The putrefactive changes which sometimes take place cause no material injury to the pepsin. After clarification the clear liquid is decanted or siphoned off, and to it is added common salt, a uniform temperature of 94° F. being maintained until the pepsin is separated by precipitation. This precipitate—the floating scum—is collected, pressed and dried. The residual solution contains practically all the "peptones," which may be obtained by allowing the salt to crystallize out and then evaporating the clear solution.

The *crude pepsin* thus obtained has a faint odor, a brownish-yellow color and a slightly saline taste. It is very active, and meets certain requirements of trade. To produce the so called *standard scale pepsin*, the crude pepsin, either dry or in a moist state, is dissolved in weak hydrochloric acid, and this solution subjected to dialysis until the salt has been separated; the purified solution is afterwards concentrated in a vacuum apparatus at a temperature not exceeding 100° or 105° F. The concentrated solution is then spread in thin layers on glass plates, about 15 inches wide and 20 inches long, with the projecting edge one-quarter inch high. These plates are placed on shelves, arranged to hold a number of them, in a drying room, at a temperature of 102° F., and well protected from dust, when the thin layer of solution is dried as rapidly as possible. When thoroughly dry, the product is scraped from the glass plates. So obtained, scale pepsin possesses a digestive power of 3,000. Powdered pepsin is obtained by grinding it in mills, in which it must be carefully protected from humidity on account of its hygroscopic nature. The yield of pepsin varies and depends upon the quality of hog stomachs used. In a test, 1,016 lbs. of membrane ready for digestion yielded 39 lbs. of high grade pepsin, or 2.8 lbs. from 100 stomachs. In another, the yield was only 1.8 lbs. from 100 stomachs.—*M. R.*, 1904, 156. For account of a process by C. R. Marshall, see *Bull. Pharm.*, 1903, 160.

² For the process for Boudault's pepsin, see U. S. D., 17th ed., 1014.

less concentrated solutions, and the proportion of peptone is increased by extending the length of time in the digestion process and raising the temperature to the utmost safe limit. Numerous pepsins of value are upon the market, and they are so readily tested that the practitioner need not be at a loss. (See *Proc. A. Ph. A.*, 1884, 1886, and 1890; *Ph. Rec.*, 1893, 104; *West. Drug.*, 1887, 69; *Am. Drug.*, 1885, 103.)

Properties.—Pepsin is in "lustrous white, pale yellow or yellowish, transparent or translucent scales or grains, or a fine white or cream-colored amorphous powder, free from any offensive odor, and having a slightly acid or saline taste. It should be not more than slightly hygroscopic. Soluble, or almost entirely soluble, in about 50 parts of water, the solution having more or less opalescence; more soluble in water acidulated with hydrochloric acid; insoluble in alcohol, ether, or chloroform. Pepsin, when in solution, is incompatible with alkalies, alkaline earths, or alkali carbonates. The presence of hydrochloric acid of greater strength than 0.5 percent. inhibits and rapidly destroys its proteolytic activity. Its solution is precipitated by the salts of many heavy metals, and by tannic acid or gallic acid. Pepsin and pancreatin in solution are incompatible with one another; if the solution be neutral or alkaline, the pancreatin gradually destroys the Pepsin, and if acid the Pepsin destroys the pancreatin. On heating a solution of Pepsin in acidulated water to 100° C. (212° F.) it becomes milky, or yields a light flocculent precipitate, and loses all proteolytic power; in a dry state it is not injured if subjected to the above temperature. The activity of Pepsin in solution is destroyed by temperatures exceeding 70° C. (158° F.). Pepsin usually has a slightly acid reaction; it may be neutral, but should never be alkaline." *U. S.*

Assay of Pepsin.—"Pepsin, *one-tenth gramme*; Egg Albumin, boiled and disintegrated, *ten grammes*; Diluted Hydrochloric Acid, Distilled Water, each, a *sufficient quantity*. Mix 9 Cc. of diluted hydrochloric acid with 291 Cc. of distilled water, and dissolve the Pepsin in 150 Cc. of the acid liquid. Immerse a hen's egg, which should be fresh, during fifteen minutes in boiling water; remove the pellicle and all of the yolk; rub the white, coagulated albumin through a clean No. 40 sieve. Reject the first portion that passes through the sieve, and place 10 Gm. of the succeeding portion in a wide-mouthed bottle of 100 Cc. capacity. Add 20 Cc. of the acid liquid, and with the aid of a glass rod tipped with cork or black rubber tubing, completely disintegrate the albumin; then rinse the rod with 15 Cc. more of the acid liquid and add 5 Cc. of the solution of Pepsin. Cork the bottle securely, invert it three times, and place it in a water-bath that has previously been regulated to maintain a temperature of 52° C. (125.6° F.). Keep it at this temperature for two and one-half hours,

agitating every ten minutes by inverting the bottle once. Then remove it from the water-bath, add 50 Cc. of cold distilled water, transfer the mixture to a narrow graduated cylinder, and allow it to stand for half an hour. The deposit of undissolved albumin should not then measure more than 1 Cc. The relative proteolytic power of Pepsin stronger or weaker than that just described may be determined by ascertaining through repeated trials the quantity of the above Pepsin solution required to digest, under the prescribed conditions, 10 Gm. of boiled and disintegrated egg albumin. Divide 15,000 by this quantity expressed in Cc. to ascertain how many parts of egg albumin one part of the Pepsin will digest." *U. S.* "If 12.5 grammes of coagulated and firm white of fresh eggs, 125 cubic centimetres of acidulated water containing about 0.2 per cent. of hydrogen chloride (HCl), and 0.005 gramme of Pepsin, be digested together at 105° F. (40.5° C.) for six hours, and shaken frequently, the coagulated white of eggs dissolves, leaving only a few small flakes, in an almost clear solution. The 'white of eggs' should be prepared by boiling quite fresh eggs in water for fifteen minutes, then immersing them in cold water, and, as soon as sufficiently cool for handling, separating the whites, washing off any fragments of yolk or membrane with water, removing the water with a clean towel, then at once rubbing the whites through a sieve having twelve meshes to a centimetre, and using the product before it has lost moisture. For the 'acidulated water' mix the official Hydrochloric Acid with water in the proportion of 1 gramme to 156 cubic centimetres; this will give a solution containing about 0.2 per cent. of hydrogen chloride (HCl)." *Br.*

In estimating the proteolytic power of pepsin by any method it is very important to adhere strictly to each requirement, otherwise great variations may be expected. (*Proc. A. Ph. A.*, 1893, 411, 722; 1894, 221; 1895, 244, 338; 1896, 260, 263; 1897, 745; *Am. Drug.*, 1894, 212; 1895, 101; *D. C.*, 1896, 52; *P. J.*, 1897, 561; *Proc. A. Ph. A.*, 1899, 307; *Ap. Ztg.*, 1900, 485, 512; *D. C.*, March, 1902.)

Three distinct types of pepsin are found in commerce: 1. Pepsins insoluble in water without the addition of traces of acids; 2. Pepsins soluble in water forming transparent solutions; 3. Pepsins not entirely soluble in water or in diluted hydrochloric acid. The objection to the insoluble pepsins is, of course, the inconvenience resulting from their insolubility in water, but, on the other hand, they are not hygroscopic, do not deteriorate so rapidly, and are active in contact with the gastric juice. The objection to the soluble pepsins is that they are hygroscopic, but they are, when good, well suited for making solutions, wines, etc.

Pepsin should always be administered in its original form. The wines and elixirs which flood the market are mostly worthless preparations, although it has been proved that an

effective wine of pepsin can be made, and small quantities of alcohol are not incompatible.¹ It is well to combine it with hydrochloric acid, and the powder is often advantageously exhibited in *infantile diarrhœa* along with bismuth subnitrate. With these exceptions, it is usually preferable to give it by itself.²

Uses.—Pepsin is said to have been first suggested as a remedy by Corvisart of Paris (*J. P. C.*, xxx. 169), and has been very largely used in cases of various character in which the digestive powers of the stomach have failed, for the purpose of supplying the place of the natural digestive ferment. Any influence for

good which it possesses is dependent upon its solvent power, which is a measure of its value. The usual dose of pepsin is from ten to fifteen grains, and it is plain that the solvent power of less than such an amount is too trifling to be of value in sustaining the digestion of an adult. Further, a large portion of the pepsin which has been exhibited has been inert, either originally or from the method of its administration, and in the great majority of cases the good result that has been ascribed to the pepsin has been due, not to it, but to the regulation of the diet and habits of the patient and to the drugs which have been exhibited along with the animal ferment. We believe that its value has been overestimated, that it has been given to adults in ridiculously small doses, and that a drachm (3.9 Gm.) of the ordinary commercial article is a moderate dose.

It has been found much more certain in its effects in the feeble digestion of infants than of adults, due probably to its being administered in proportionately much larger doses. To a babe six months old, suffering from *indigestion* and consequent *diarrhœa*, one grain of pepsin or ten grains of saccharated pepsin may be given after each feeding with a rational expectation of benefit.

Dose, of official pepsin, may be set down as from ten to fifteen grains (0.65 to 1.0 Gm.).

Off. Prep.—Glyceritum Pepsini, *Br.*

PETROLATUM. U. S. (Br.)

PETROLATUM [Petroleum Ointment, *Petrolatum Mollè*, *Petrolatum Spissum*, *Pharm.* 1890]

(pêt-rô-lă'tum)

"A mixture of hydrocarbons, chiefly of the methane series, obtained by distilling off the lighter and more volatile portions from petroleum, and purifying the residue." *U. S.* "A semi-solid mixture containing soft members of the paraffin series of hydrocarbons; usually obtained by purifying the less volatile portions of petroleum." *Br.*

Paraffinum Mollè, Soft Paraffin, *Br.*; Adeps Petrolei, Unguentum Paraffinum; Soft Petrolatum, Cosmoline, Vaseline, Paraffin Jelly, Soft Petroleum Ointment, Hard Petroleum Ointment, Hard Petrolatum; Pétroléine, *Fr. Cod.*; Grosse minérale, Pétroléine, *Fr.*; Welches Paraffin, Paraffinsalbe, *G.*; Vaselina, *It.*, *Sp.*

Petrolatum in its various forms has of late years acquired considerable importance, under various trade names, as a bland neutral body well fitted to take the place of lard as a base for ointments and for other purposes. It is prepared from the residue left in the stills after a distillation of petroleum *in vacuo*, or from the residue or sediment deposited in tanks containing crude petroleum, of which large quantities have collected in the storage tanks in the oil districts of Western Pennsylvania. The substances known commercially as *cosmoline* (*Unguentum Petrolei*) and *vaseline* are now

¹ *Liquor Pepsini*, *U. S.* 1880, *Solution of Pepsin, Liquid Pepsin*; *Pepsine Liquide*, *Fr.*; *Pepsin-lösung*, *G.*—"Saccharated Pepsin, forty parts [or four hundred grains]; Hydrochloric Acid, twelve parts [or one hundred and ten minims]; Glycerin, four hundred parts [or seven fluidounces]; Water, five hundred and forty-eight parts [or twelve fluidounces], to make one thousand parts [or about twenty fluidounces]. Dissolve the Saccharated Pepsin in the Water, previously mixed with the Hydrochloric Acid, add the Glycerin, let the mixture stand twenty-four hours, and filter." This preparation originated with Prof. Emil Scheffer, who suggested a process (see *A. J. P.*, 1870, p. 98), in which six pounds of the mucous membrane of hogs' stomachs were macerated with four pounds of glycerin and four pints of water containing six ounces of hydrochloric acid for thirty-six hours. The mass was then strained, and macerated with fresh water and again strained, and the operation repeated until ten pints were obtained. This process was simplified after the publication of his formula for Saccharated Pepsin, official in *U. S.* 1880, and is based upon his improved process. The solution contains 4 per cent. of Saccharated Pepsin, while Scheffer's original formula (*A. J. P.*, 1871, p. 5) was weaker, containing but 1.6 per cent. This liquid is transparent, either colorless, or having a yellowish color, and a sweetish, agreeable taste, which is slightly acidulous. "It should not become mouldy, nor acquire a disagreeable, fetid odor, when kept for some time." *U. S.* 1880. It should be freshly made, as it gradually loses its powers of digestion when long kept. This preparation, if in good condition, undoubtedly has all the remedial virtues of pepsin but is deficient in strength. The dose is one-half to two fluidounces (15 to 60 Cc.)." *U. S. D.*, 16th ed.

Pepsinum Saccharatum, *U. S.* (1890), *Saccharated Pepsin*.—"Pepsin, ten grammes [or 154 grains]; Sugar of Milk, recently dried, and in No. 30 powder, ninety grammes [or 3 ounces av., 76 grains], to make one hundred grammes [or 3 ounces av., 230 grains]. Triturate the Pepsin with the Sugar of Milk to a fine, uniform powder. Keep the product in well-stoppered bottles." *U. S.* As stated in the article "Pepsinum," this powder is made by diluting strong pepsin with powdered sugar of milk. It is about six times stronger than the saccharated pepsin of the *U. S. P.* 1880. (See above.) "Saccharated Pepsin, when tested by the process given under Pepsin (see *Pepsinum*), with the modification that 0.67 Gm. of it are to be taken in preparing solution B, should digest 300 times its own weight of freshly coagulated and disintegrated egg albumen." *U. S.* 1890.

² Gastric juice was many years ago employed by P. S. Physick, the celebrated surgeon of Philadelphia, with considerable success, as a local application to cancers and sloughing ulcers, with the view of removing the dead bone and flesh, correcting the offensive odor, and yielding a healthful stimulus to the diseased surface. It was also used with success, by Ellsworth of Hartford, Connecticut, for dissolving a portion of tough animal food which had become impacted in the œsophagus of a lad affected with stricture of that passage. The gastric juice of a pig was used. (*B. M. S. J.*, April 17, 1856.) The inner coat of the gizzard of the South American ostrich is said, in the state of powder, to be used in Buenos Ayres as a remedy in dyspepsia (*E. S. Wayne, A. J. P.*, March, 1868, p. 123), and the dried crops and gizzards of chickens and turkeys have long been used in some portions of this country as a domestic remedy. For an account of *Rennet*, see PART II.

made on a large scale from residues, but more largely from what are termed "reduced oils," that is, crude oils from which the lighter fractions (those included under the heads of petroleum benzin, naphtha, illuminating and paraffin oils) have been removed by distillation. This process of reducing would leave an increasing amount of black pyrogenous products in the residue, were it not that the reducing is carried out under diminished pressure, by what is termed the "vacuum process," in which, moreover, the heat is not applied directly to the still bottoms, but by means of coils of pipe, through which superheated steam is made to pass. These reduced oils can be brought to 337.7° C. (640° F.) fire-test without acquiring the slightest pyrogenous odor. They are then filtered through well-dried bone black, in chambers kept at a temperature of from 43.3° to 54.4° C. (110° to 130° F.), or in some cases higher. The first portions of the filtrate are colorless, and then pass from a light straw or amber color to a color red by transmitted light and light green by reflected light. The latter product is known as "cylinder stock," and is highly prized as a lubricating oil. The clearer portion of the filtrate is then brought to the proper melting point, if necessary, by the addition of pure block paraffin, which dissolves perfectly in the warm liquid oil. The crude oil tank residues are purified in a similar manner. The "B. S. Oil," or "rod wax," as it is technically termed, is placed in a still, heat applied, and after the lighter products have distilled over, and indications of congelation are noticed when a portion of the distillate is allowed to cool, the heat is withdrawn, and the contents of the still, after having cooled, are transferred gradually to a percolator which contains recently heated animal charcoal. In place of bone black, clay has in recent years been quite largely used for clarifying purposes, the same being revived by heat. A somewhat different process is used in Germany; the crude product is derived from crude *ozokerite*, obtained from Alsace and Galicia, or American residue is sometimes used. 1. The oil is heated by steam to about 30° C. (86° F.), mixed, at this temperature, with 10 per cent. of its weight of sulphuric acid of 60° B., stirred for half an hour, and then allowed to stand at rest, so that the carbonized portions may separate. 2. When clear, the oil is washed with an aqueous solution of potassium dichromate, whereby any remaining excess of sulphuric acid is at the same time removed. 3. The residue from the acid treatment is mixed with lime, neutralized, and disposed of to fertilizer factories. 4. The clear oil from the second step of the process, after being washed, is heated by steam to 80° C. (176° F.), mixed with 10 per cent. of its weight of granular animal charcoal, and then allowed to stand at rest, to permit the animal charcoal to settle. 5. After the latter is separated, the liquid portion is filtered through filters heated by

steam. 6. The residuary magma of animal charcoal is subjected to hydraulic pressure, the expressed oil filtered, and the solid residue again used in the next operation, a sufficient quantity of fresh animal charcoal being added to make up for any loss or waste. (*Ph. Centralh.*, 1881, No. 42; *N. R.*, Feb. 1882.)

The commercial varieties of petrolatum may be classed under two heads: 1. Those which, like the American vaseline, are obtained as a ready formed mixture of hydrocarbons of gelatinous consistence; 2. Those made by directly mixing solid paraffin of low melting point with heavy lubricating oil, such as are known in Germany as "artificial vaseline." The latter varieties are less homogeneous, and are liable to deposit granules of paraffin on keeping, and hence are not so suited for the preparation of ointments as true American petrolatum.

In warm ether, American petrolatum dissolves freely to a clear solution exhibiting a strong blue fluorescence, and the liquid remains clear, or at most becomes only slightly turbid, on cooling. German petrolatum, on the contrary, is said to form a thick solution with warm ether, and to give a considerable deposit on cooling. Russian petrolatum is stated to dissolve completely in warm ether and give a clear solution which becomes turbid on cooling. (*Allen, Com. Org. Anal.*, 2d ed., 1887, ii. p. 408.) In the U. S. P. (8th Rev.) there are three forms of Petrolatum as follows: Petrolatum, Petrolatum Album, and Petrolatum Liquidum. In the British Pharmacopœia there are three as follows: Paraffinum Liquidum, Paraffinum Molle, and Unguentum Paraffini. The Petrolatum of the U. S. P. (8th Rev.) corresponds with the Petrolatum Spissum of the U. S. Pharm. 1890. The Paraffinum Molle of the British Pharmacopœia resembles the Petrolatum Molle of the U. S. P. 1890, but is somewhat softer in consistence.

Chemical Constitution.—Petrolatum, as made from American petroleum, consists mainly of the higher members of the paraffin series, but undoubtedly contains also the higher olefines. These may possibly alter in time, and give rise to rancidity, although this is not certainly established. The paraffins, which make up the bulk of it, are not capable of direct oxidation, and are therefore not affected by atmospheric influences. Petrolatum contains hydrocarbons of the paraffin series, like $C_{16}H_{34}$, $C_{17}H_{36}$, $C_{18}H_{38}$, etc., up probably to $C_{32}H_{66}$, together with hydrocarbons of the olefine series, $C_{16}H_{32}$, $C_{17}H_{34}$, etc. These latter are less concrete than the corresponding paraffin hydrocarbons, and give petrolatum its oleaginous characters.

Properties.—The U. S. Pharmacopœia describes Petrolatum as follows: "An unctuous mass, of about the consistence of an ointment, varying in color from yellowish to light amber, having not more than a slight fluorescence, even after being melted, transparent in thin layers,

completely amorphous; without odor or taste, but giving off, when heated, a faint petroleum-like odor. If a portion of Petrolatum be liquefied and brought to a temperature of 60° C. (140° F.), it should have a specific gravity of from 0.820 to 0.850. Petrolatum is insoluble in water; scarcely soluble in cold or hot alcohol, or in cold, absolute alcohol, but soluble in boiling absolute alcohol, and readily soluble in ether, chloroform, carbon disulphide, oil of turpentine, petroleum benzin, benzene, and fixed or volatile oils. The melting point of Petrolatum ranges between 45° and 48° C. (113° and 118.4° F.). If heated on platinum foil to a still higher temperature, Petrolatum should be completely volatilized without emitting any acrid odor. If melted Petrolatum be well shaken with water the latter should not redden blue litmus paper. If 10 Gm. of Petrolatum be digested at 100° C. (212° F.) for half an hour with 10 Gm. of sodium hydroxide and 50 Cc. of water, the aqueous layer separated and supersaturated with sulphuric acid, no oily or solid substance should separate (absence of *fixed oils or fats of animal or vegetable origin and of rosin*). If 2 volumes of concentrated sulphuric acid be added to 1 volume of melted Petrolatum in a test-tube placed in hot water, and the contents occasionally agitated during fifteen minutes, the acid should not acquire a deeper tint than brown nor lose its transparency (limit of *readily carbonizable organic impurities*)." *U. S.* The British Pharmacopœia describes it as "white or yellow, translucent, soft, unctuous to the touch, free from acidity, alkalinity, or any unpleasant odor or flavor, even when warmed to 120° F. (48.9° C.). Specific gravity at the melting point 0.840 to 0.870. Melts at 96° to 102° F. (35.5° to 38.9° C.) or even somewhat higher, volatilizes without giving off acrid vapors, and burns with a bright flame, leaving no residue. Insoluble in water, slightly soluble in *absolute alcohol*, freely soluble in ether, chloroform, and benzol. After treating with boiling solution of sodium hydroxide the aqueous liquid yields no precipitate or oily matter on adding excess of acid (absence of fixed oils, fats, and resin)." *Br.* As it is found in the market, petrolatum varies in color, odor, and melting point. The statement frequently made by the manufacturers that it is unalterable in the air is incorrect, as we have frequently noticed that exposure to light and air causes it to assume a disagreeable odor resembling that of crude petroleum. It has been observed to have at times irritating properties. These may be due to imperfect removal of the sulphuric acid or similar agents used, but are more probably caused by rancidity or decomposition of the higher olefines.

Uses.—Petrolatum is used exclusively as a bland neutral protective dressing, and as a substitute for fatty materials in ointments. M. M. Griffith (*N. R.*, May, 1880) asserts that the crude semi-solid petroleum (*rod wax*), as it

accumulates on the casings, etc., about oil wells, is an invaluable remedy in *chronic bronchitis* and *incipient phthisis*. It is readily formed into three-grain pills, and may be given until it produces eructations. He has used the following formula with advantage: Petroleum mass, 480 gr.; Pulv. Cubebæ, Pulv. Doveri, $\overline{\text{aa}}$ 360 gr., to make pill mass (pills 5 gr.). *Huile de Galian* is a similar product, which has long been famous in France as a remedy in lung diseases. N. Randolph has shown that when taken internally, in doses of from one to four drachms (3.9 to 15.5 Gm.), cosmoline acts simply as a feeble laxative and soothes irritation, so as to be advantageous in inflammations of the gastro-intestinal mucous membrane.

PETROLATUM ALBUM. U. S.

WHITE PETROLATUM

(pēt-ŕo-lă'tûm ăl'bûm)

"A colorless mixture of hydrocarbons, chiefly of the methane series, obtained by distilling off the lighter and more volatile portions from petroleum, and purifying the residue." *U. S.*

Preparation.—White petrolatum was introduced for the first time into the *U. S. P.* (8th Rev.) under its present official title; there are reasons for believing that much that is in the market is not the natural product deprived of its color by treatment with animal charcoal, but an artificial compound made by melting together paraffin wax and liquid petrolatum, and stirring until cold.

Properties.—It is officially described as "a white unctuous mass, of about the consistence of an ointment, transparent in thin layers, completely amorphous; without odor or taste. In other respects White Petrolatum has the characteristics of, and should respond to the tests given under, *Petrolatum*." *U. S.*

Uses.—See *Petrolatum*.

Off. Prep.—Ceratum, *U. S.*; Ceratum Camphoræ, *U. S.*; Ceratum Plumbi Subacetatis, *U. S.*; Unguentum Acidi Borici, *U. S.*; Unguentum Hydrargyri Ammoniatum, *U. S.*; Unguentum Phenolis, *U. S.*; Unguentum Zinci Stearatis, *U. S.*

PETROLATUM LIQUIDUM. U. S. (Br.)

LIQUID PETROLATUM

(pēt-ŕo-lă'tûm lîq'uŭ-dûm)

"A mixture of hydrocarbons, chiefly of the methane series, obtained by distilling off most

of the lighter and more volatile portions from petroleum, and purifying the liquid residue." *U. S.* "A clear oily liquid, obtained from petroleum, after the more volatile portions have been removed by distillation." *Br.*

Paraffinum Liquidum, Br., Liquid Paraffin; Paraffine liquide, Huile de Paraffine, *Fr.*; Flüssiges Paraffin, Paraffinöl, *G.*; Acete de paraffina, *Sp.*

Preparation.—Liquid petrolatum is made by distilling the residuary liquid boiling between 330° and 390° C., obtained after removing the lighter hydrocarbons from petroleum. It is purified and decolorized by first treating it with sulphuric acid and then with caustic soda and passing it while hot, though animal charcoal. By cooling, some solid paraffins will separate; the liquid is then redistilled, and the portion boiling below 360° C. rejected. It has been sold under various proprietary names as *albolene*, *glycoline*, etc., and since its introduction into the *U. S. P.* 1890 has been largely used in medicine and for pharmaceutical purposes.

Properties.—It is described officially as "a colorless, or very slightly yellowish, oily, transparent liquid, without odor or taste, but giving off, when heated, a faint odor of petroleum. Specific gravity: about 0.870 to 0.940 at 25° C. (77° F.). It is insoluble in water; scarcely soluble in cold or hot alcohol, or in cold absolute alcohol, but soluble in boiling absolute alcohol, and readily soluble in ether, chloroform, carbon disulphide, oil of turpentine, petroleum benzin, benzene, and fixed or volatile oils. When heated on platinum foil, Liquid Petrolatum is completely volatilized without emitting acid vapors. If a test-tube be half filled with Liquid Petrolatum and a piece of moistened blue litmus paper be introduced, upon shaking the liquid vigorously the paper should not be reddened (absence of *acid impurities*). In other respects Liquid Petrolatum has the characteristics of, and should respond to the tests given under, *Petrolatum*." *U. S.* The British Pharmacopœia describes it as "colorless, odorless, tasteless, not fluorescent. Boiling point not below 680° F. (360° C.). Specific gravity from 0.885 to 0.890. 3 cubic centimetres, heated with an equal volume of *sulphuric acid* in a test-tube placed in boiling water for 10 minutes, with frequent agitation, should not color the separated layer of acid of a deeper tint than pale brown. *Alcohol* (90 per cent.) boiled with Liquid Paraffin should not redden *blue litmus paper* (absence of acid). A mixture of 4 cubic centimetres with 2 of *absolute alcohol*, and 2 drops of a clear saturated solution of Lead Oxide in *solution of sodium hydroxide*, should remain colorless when kept at 158° F. (70° C.) for 10 minutes (absence of sulphur compounds)." *Br.*

Uses.—Liquid petrolatum is much used as a soothing local application in inflammation of the mucous membrane in the nose, throat, larynx, and even bronchial tubes. It is usually applied by means of an atomizer, and can be

made the vehicle for carrying medicinal substances. It has also been used internally, preferably in the form of emulsion.¹

PHENOL. *U. S.* (Br.)

PHENOL [Carbolic Acid, Acidum Carbolicum, Pharm. 1890]

(phē'nōl)

$C_6H_5OH = 93.34$

"Hydroxybenzene, obtained either from coal-tar by fractional distillation and subsequent purification, or made synthetically. It should contain, when assayed by the process given below, not less than 96 percent. of absolute Phenol. It should be kept in dark amber-colored, well-stoppered bottles." *U. S.* "Phenol, C_6H_5OH , commonly termed carbolic acid, is obtained from coal-tar oil by fractional distillation." *Br.*

Acidum Carbolicum, Br., also *U. S.* 1890; Acidum Phenicum s. Phenylum Crystallisatum; Phenic Acid, Phenylic Acid, Phenylic Alcohol, Phenic Alcohol, Benzophenol; Phénol, Acide carbolique, Acide Phénique, *Fr. Cod.*; Hydrate de Phényle, *Fr.*; Acidum carbolicum, *P. G.*; Karbolsäure, Phenylsäure, Phenylalkohol, *G.*; Fenolo cristallizzato, Acido carbolico, *It.*; Acido fenico, *Sp.*

This important medicine was discovered in 1834, in the tar of coal, by Runge, who gave it the name of carbolic acid. When on the subject of its composition, we shall have occasion to show that, although more closely related chemically with the alcohols than the acids, it belongs to a peculiar class known in common as *phenols*. The *U. S. P.* (8th Rev.) dropped the names Acidum Carbolicum and carbolic acid and adopted the correct title of Phenol for this substance. The British Pharmacopœia recognizes the name Acidum Carbolicum, but uses "phenol" as the English name for this substance.

Preparation.—For the commercial preparation of phenol the light oil fraction is collected until a sample of the oil that runs from the still sinks in water. This fraction, with a sp. gr. of from 0.94 to 0.99, boils between 90° and 250° C. and contains from 4 to 10 per cent. of acids, and therefore nearly all the true phenol which boils at 182° C. The oil from which the phenol is to be extracted is agitated with a weak solution of sodium hydroxide, 10 per cent.

¹ *Emulsions of Liquid Petrolatum.*—E. Fullerton Cook proposed the following formulas:

Emulsion of Liquid Petrolatum is made by mixing 4 fl. oz. of liquid petrolatum with 2 oz. of powdered acacia in a dry mortar, adding 4 fl. oz. of water all at once, and triturating until a perfect emulsion results; then add 82 minims of oil of wintergreen and enough water to make 1 pint.

Emulsion of Liquid Petrolatum with Hypophosphites is made in the same way initially, but dissolving in 6 fluidounces of the water to be finally added, 330 grains of calcium hypophosphite and 110 grains each of potassium and sodium hypophosphite. Both formulas have proven satisfactory. The vegetable oil, supposed by some to be necessary, is not necessary or advantageous. (*A. J. P.*, 1903, 260-264.)

strength being strong enough. If a stronger solution is used many impurities, like naphthalene, are dissolved and contaminate the finished product. After agitation, the mixture, on standing, separates into two layers, the upper consisting of the extracted oil and the lower the solution of sodium phenolate. To this solution, after separation from the oily layer, an amount of hydrochloric or diluted sulphuric acid calculated from a special test with a small portion, as just sufficient, is then added in order to set the phenol free. It separates as an oily layer upon the surface, and, after being washed with a saturated solution of sodium chloride, is dried over calcium chloride and again distilled. The product thus obtained crystallizes out largely on a cooled surface, and, after removing the crystals from adhering liquid, and drying them by pressure, they are again submitted to the same process of distillation. Only by such a detailed procedure can phenol be separated from its homologues, like cresol (cresylic acid), $C_6H_4(CH_3)OH$, which accompany it, smell much like it, and boil between $185^\circ C.$ ($365^\circ F.$) and $200^\circ C.$ ($392^\circ F.$).

Church (*Chem. News*, Oct. 13, 1871) proposed to prepare pure phenol by agitating the best commercial product with 20 parts of water, siphoning off the clear solution from the undissolved portion which retains the impurities, and adding to the solution pure sodium chloride to saturation, when the purified phenol rises to the top, and may afterwards be dehydrated by distillation with lime.

Within recent years German manufacturers have put upon the market "*synthetical phenol*," for which is claimed a greater purity than that extracted from coal tar. It may be made synthetically in one of two ways,—either from benzene, which is converted into *benzene-sulphonic acid*, the sodium salt of which is then fused with an excess of sodium hydroxide, producing sodium phenolate and sodium sulphite, from which, on the addition of sulphuric or hydrochloric acid, the phenol separates and may be distilled off; or a pure aniline oil is taken, neutralized with sulphuric acid, and to the acid solution sodium nitrite is added. The nitrous acid liberated forms at first *diazobenzene sulphate*, but this at once decomposes into phenol, sulphuric acid, and nitrogen, the reactions being as follows:

The synthetic phenol melts at 41° to $42^\circ C.$, and boils at $178^\circ C.$ ($352.4^\circ F.$). It is as yet considerably dearer than the coal tar product.

Commercial Forms.—In one of his publications in reference to phenol, F. Crace Calvert, to whom probably more than to any other person is due the introduction of this substance into use in Great Britain and the United States, informed us that the phenol obtained

by Laurent, melting at $34^\circ C.$ ($93^\circ F.$), and boiling at $186^\circ C.$ ($367^\circ F.$), was not quite pure. By successive steps of improvement in the process employed by the manufacturing house of Manchester with which he was connected, they had at length succeeded in preparing the pure crystallized acid, without color or sulphurous odor, but, unfortunately, this statement was not accompanied with an account of the means by which the end had been attained. As the products of this factory are those now generally used, a brief notice, derived from the same source, of the forms of the drug prepared by them, and now circulating in the market, is desirable. 1. A pure phenol is prepared, crystallizing in white prismatic crystals, but, as usually sold, in a white, hard, fused mass, which differs from Laurent's in being soluble in 20 parts of water instead of 33 parts, fusible at $41^\circ C.$ ($106^\circ F.$) instead of $34^\circ C.$ ($93^\circ F.$), and boiling at $182^\circ C.$ ($359^\circ F.$) instead of $186^\circ C.$ ($367^\circ F.$). This should be preferred for internal use. 2. The second form is less pure. Like Laurent's, it is white, solid, and fusible at $34^\circ C.$ ($93^\circ F.$), and may be employed for external purposes, whether in medicine or surgery. 3. A third quality is known in commerce as solution No. 4, which is not crystallizable at ordinary temperatures, and contains at least 10 per cent. of water, with varying quantities of homologous acids. 4. The fourth and cheapest form is that of a nearly colorless liquid, which is a mixture of phenols and cresols. Diluted with 100 parts of water or more, it may be used for the coarser antiseptic and disinfecting purposes out of doors, as in cess-pools and sewers. Besides these forms of phenol, which issue from the manufacturing establishment of Calvert, there are others from different sources, generally in the liquid state, which are usually of a brownish color, and consist of mixtures of phenol with cresol, coloring matter, etc., and of which phenol often constitutes but a small proportion. These are often imported from Germany. They should not be used internally; but for disinfectant and antiseptic purposes they are probably equal to solutions of the pure phenol, as the cresol is said to be quite as powerfully disinfectant as the phenol, if not more so. Phenol of excellent quality is now made in the United States.

These impure liquors are sold sometimes under the improper name of *coal tar creosote*. They were formerly recognized in the U. S. Pharmacopœia (*Acidum Carbolicum Crudum*)¹

¹ *Acidum Carbolicum Crudum, Crude Carbolic Acid*, U. S. 1890, was officially described as "a nearly colorless, or reddish, or brownish-red liquid, of a strongly empyreumatic and creosote-like odor; having a numbing, blanching, and caustic effect upon the skin or mucous membrane; and gradually turning darker on exposure to air and light. The aqueous solution of Crude Carbolic Acid has a slightly acid reaction on litmus paper. In an aqueous solution of the Acid, bromine water produces a white precipitate. Crude Carbolic Acid should not be soluble in less than 15 parts of water at $15^\circ C.$ ($59^\circ F.$), and the aqueous solution should not have an alkaline reac-

U. S. 1890), but are now introduced in a purified form and called *Cresol* in the U. S. P. (8th Rev.).

Properties.—Phenol, in its pure state, is a solid at ordinary temperatures, crystallizing in minute plates or long rhomboidal needles, white or colorless, of a peculiar odor recalling that of creosote, and an acrid burning taste. Its sp. gr. is 1.065. (Lemaire.) It is likely to be colored pinkish or brown under the influence of light and air. This reddening has been ascribed to various causes, such as ammonia and ammonium nitrite in the air, rust spots in tinned iron vessels, alkali in glass vessels, organic matter, etc. It is said to be due to oxidation; stannous chloride solution acquires a green color when shaken with the red colored phenol. Demant recommends the removal of the red color by adding to 89 parts of the melted substance 11 parts of alcohol, subjecting the mixture to freezing, and then draining off the portion remaining liquid. Perfectly white crystals can be thus obtained. A slight discoloration does not interfere with any of the medicinal uses of phenol. It deliquesces on exposure, and becomes liquid, and the presence of water in the smallest proportion causes it to liquefy. It is customary to add 10 per cent. of water or glycerin to phenol for dispensing, as it is more convenient to use in a liquid form. Such a form is now official (see *Phenol Liquefactum*). Its solution in glycerin is very useful, as the glycerite mixes with water very readily. (See *Glyceritum Phenolis*.) When diluted it has a sweetish taste with a slightly burning after-taste, and a faintly acid reaction. When quite pure it melts at 41° C. (106° F.), forming an oily looking, colorless liquid, and boils at 182° C. (359° F.) (Calvert); but, as often met with, its point of fusion is lower, and that of volatilization higher, than those named. The official tests and requirements are as follows: "Colorless, interlaced, or separate needle-shaped crystals, or a white, crystalline mass, sometimes acquiring a reddish tint; having a characteristic, somewhat aromatic odor; when copiously diluted with water, it has a sweetish taste, with a slightly burning after-taste, and, when undiluted, cauterizes and whitens the skin and mucous membrane. Soluble in 19.6 parts of water at 25° C. (77° F.), the solubility varying according to the degree of hydration of the Phenol; very soluble in alcohol, ether, chloroform, benzene, carbon disulphide, glycerin, fixed and volatile oils; almost insoluble in petroleum benzin. When gently heated, Phenol melts, forming a highly refractive liquid. It is also liquefied by the addition of about 8 percent. of water. If the Phenol be liquefied

by a gentle heat, and then slowly cooled under constant stirring, until it is partly recrystallized, the semi-liquid mass should have a temperature (remaining stationary for a short time) not lower than 40° C. (104° F.). Phenol should have a boiling point not higher than 188° C. (370.4° F.). A lower boiling point or a higher melting point, indicates a less hydrated Phenol. When heated upon a water-bath, it should be volatilized without leaving a residue. The vapor is inflammable. Phenol is faintly acid to blue litmus paper." U. S. The Br. Ph. gives its melting point at not lower than 102° F. (38.8° C.), and its boiling point not higher than 359.6° F. (182° C.) Specific gravity at the melting point from 1.060 to 1.066. "Freely soluble in alcohol (90 per cent.), ether, benzol, chloroform, carbon bisulphide, glycerin, in the fixed and volatile oils, and in solutions of alkalies. Exposed to moist air it may acquire a pinkish tinge. At 60° F. (15.5° C.), 100 parts of Phenol should be liquefied by the addition of 10 parts of water, should form a clear liquid with 30 to 40 of water, and should be completely dissolved by 1200 of water. The aqueous solution should be clear and colorless." Br. Its solubility in water increases on heating the water; at 84° C. (183.2° F.) both liquids are miscible in all proportions. Its solution is, if pure, colorless, and remains so, but, if impure, is colored brownish by exposure. It is but slightly soluble in cold petroleum benzin, but dissolves largely on heating. *Sodium sulphorinate* has been used to increase the solubility of phenol, the advantage being that it will retain 40 per cent. of phenol in solution without destroying its antiseptic power, making a solution without causticity.

"Its aqueous solution yields, with bromine water, a white precipitate of tribromphenol, which at first redissolves, but becomes permanent as more of the reagent is added, and appears crystalline when viewed under the microscope. On adding to 10 Cc. of an aqueous solution of Phenol (1 in 100) 1 drop of ferric chloride T.S., the liquid acquires a violet-blue color, which is permanent. One volume of cold, liquefied Phenol (rendered liquid by the addition of 8 percent. of water) forms, with 1 volume of glycerin, a clear liquid which is not rendered turbid by the addition of 3 volumes of water (absence of creosote and of cresol)." U. S. "Phenol does not immediately redden blue litmus paper. It does not rotate the plane of a ray of polarized light. It coagulates solution of albumen and collodion, and liquefies Camphor. Test-solution of ferric chloride strikes a deep purple color, and excess of solution of bromine gives a white precipitate, with a cold aqueous solution of Phenol. An aqueous solution of Phenol mixed with one-fourth of its volume of solution of ammonia, and then with a few drops of solution of chlorinated soda, becomes blue after a time or immediately on gently heating.

tion (absence of alkalies). If 50 volumes of the Acid be thoroughly agitated with 950 volumes of water, in a capacious vessel, on allowing the mixture to separate, the undissolved portion should not exceed 5 volumes, or 10 per cent. by volume of the acid (limit of other less soluble constituents of coal-tar)." U. S. 1890. (See *Cresol*.)

One volume of Phenol, liquefied by the addition of 10 per cent. of water, forms with 1 volume of glycerin a clear liquid which is not rendered turbid by the addition of 3 volumes of water (absence of cresol)." Br.

The U. S. Pharmacopœia (8th Rev.) gives a method of assaying phenol as follows:

Assay.—"Dissolve 1.556 Gm. of the Phenol to be valued in a sufficient quantity of water to make 1000 Cc. Transfer 25 Cc. of this solution (containing 0.0389 Gm. of Phenol) to a glass-stoppered bottle having a capacity of about 200 Cc., add 30 Cc. of tenth-normal bromine V.S., then 5 Cc. of hydrochloric acid, and immediately insert the stopper. Shake the bottle repeatedly during half an hour, then remove the stopper just sufficiently to introduce quickly 5 Cc. of an aqueous solution of potassium iodide (1 in 5), being careful that no bromine vapor escapes, and immediately stopper the bottle. Shake the latter thoroughly, remove the stopper and rinse it and the neck of the bottle with a little water, so that the washings may flow into the bottle, and then add 1 Cc. of chloroform and shake well. Add, from a burette, tenth-normal sodium thiosulphate V.S., until the iodine tint is exactly discharged, and does not reappear after thorough agitation. Note the number of Cc. of tenth-normal sodium thiosulphate V.S. consumed (which should not exceed 6 Cc.). The percentage of absolute Phenol is found by subtracting the number of Cc. of tenth-normal sodium thiosulphate V.S. used, from 30 (the number of Cc. of bromine V.S. originally added), and multiplying the remainder by 4." U. S. For methods of assaying Phenol see *Y. B. P.*, 1891, 190; *Chem. News*, 1891, 74; *J. P. C.*, 1894, 105; *A. J. P.*, 1892, 614; *Ph. Centralh.*, 1892, 479; *D. C.*, 1896, 158; *A. J. P.*, 1898, 369.

Though nearly neutral to test paper, it combines feebly with some bases, its salts being decomposed by carbon dioxide, and those with the alkalis having an alkaline reaction. The potassium phenolate is said to be decomposed even by water. Nitric acid converts it into picric acid, for the manufacture of which it is largely used. It reduces many metallic salts, especially those of silver and copper, and coagulates collodion. Bromine water, added in excess to a weak solution, produces a flocculent white precipitate. This precipitate, which consists of tribromophenol, $C_6H_2Br_3.OH$, with some tribrom-phenol-bromide, $C_6H_2Br_3.OBr$, is so insoluble that it separates even in the most dilute solutions, and affords an extremely delicate test. In 24 hours a solution containing but 1-60,000th of phenol gives the reaction. (Allen, *Com. Org. Anal.*, 2d. ed., vol. ii. p. 540.) If an aqueous solution of phenol be gently warmed with ammonia and solution of sodium hypochlorite (avoiding excess), a deep blue color is obtained, which is lasting, but turns to red on the addition of acids. Solutions containing 1 part of phenol in 5000

parts of water react well when 20 Cc. are employed. Much smaller quantities give the reaction after a time. (*Ibid.*, p. 539.) Ferric chloride (avoiding excess) gives a fine violet color, by which 1 part of phenol in 3000 parts of water can be detected. The presence even of neutral salts often interferes with this reaction.

The substances with which phenol is most likely to be confounded are cresol or cresylic acid and creosote, the former, like it, extracted from coal tar, the latter from wood tar exclusively. As cresol is incapable of crystallizing at ordinary temperatures, the two cannot be confounded in the solid state, and, as before observed, its presence in the liquid state is of little consequence, as its virtues are of the same kind, and at least equal. Its boiling point, however, is considerably higher than that of phenol, being about $400^{\circ} F.$, and it may, therefore, be supposed to be present in any suspected liquid which will not crystallize at any common temperature, or boil under $202^{\circ} C.$ ($395^{\circ} F.$) to $204^{\circ} C.$ ($400^{\circ} F.$). It is also distinguished by being less soluble in water, ammonia water, glycerin, and solution of sodium hydroxide than is the case with phenol, but it is more soluble in petroleum benzin. (Allen.) (*A. J. P.*, Jan. 1879.) Creosote is distinguished by its lower density, its liquid form, and its higher boiling point; by its insolubility in strong ammonia water, or in 6 per cent. sodium hydroxide solution, as well as its insolubility in pure glycerin (see *Creosotum*); by not coagulating collodion and albumin; and by the different effects on it of strong nitric acid, which with phenol produces pure picric or trinitrophenic acid, and with creosote, oxalic acid, resinous matter, and but a small proportion of picric acid. (Calvert, *L. L.*, 1863, p. 523.) Phenol differs also in having no effect on polarized light.

The commercial phenol powders and liquids all contain not only cresol, but also nearly inactive and valueless neutral tar oils, and it is important to be able to determine the percentage of the tar acids and that of simple tar oils in a commercial sample. John Muter (*A. J. P.*, Nov. 1887, p. 581) has worked out a simple method for this, based upon the following four observed facts; 1. Phenol, cresol, and their homologues are completely soluble when shaken up with a 5 per cent. solution of sodium hydroxide; 2. Liquefied phenol and the corresponding cresol are insoluble in a saturated solution of sodium chloride; 3. In the presence of a sufficient excess of alkali even a largely diluted solution may be boiled down without the slightest appreciable loss of phenol or cresol; 4. Tar oils and naphthalene are only very slightly dissolved by alkali, and may be perfectly removed from the solution by agitating it with benzene.

E. W. Davy proposes, as a test for phenol, sulpho-molybdic acid, made by dissolving 1 part of molybdic acid in 10 or even 100 parts

of pure concentrated sulphuric acid; 3 or 4 drops of this solution are added to the phenol placed on white porcelain; a beautiful blue coloration will be produced upon standing, particularly if the liquid be gently heated; if this reagent is applied to wood creosote in aqueous solution, a brownish-red color is produced. Phenol in creosote may be detected by distilling an aqueous solution of the mixture; the first portion of the distillate will give the reaction for creosote, the last portion that for phenol. (*P. J.*, June 22, 1878.)

Composition.—The view of the composition of phenol now universally accepted is that it is the hydroxyl (OH) derivative of benzene, C_6H_5 , and its formula would therefore be $C_6H_5.OH$. This would ally it to the alcohols, and it may be compared, in fact, to what are known as *tertiary* alcohols. The *primary* alcohols, like ethyl alcohol, $C_2H_5.OH$, yield corresponding aldehydes and acids on oxidation. The counterpart of these in the aromatic series are the aromatic alcohols, like $C_6H_5.CH_2.OH$, which yield benzoic acid, $C_6H_5.COOH$, on oxidation. The name *phenols* has therefore been given to these derivatives in which H of the benzene group is replaced by OH. Phenol is commonly called *carbolic acid*, but its claims to be considered as an acid are very feeble, as, though it combines with salifiable bases, it is incapable of neutralizing the alkalies, does not affect the color of litmus, and may be separated from its combinations with great facility, sometimes, it is asserted, even by water. Shaken in the liquid form with one-fourth of water, and cooled at $40^\circ F.$, it crystallizes in the form of a hydrate, $C_6H_5.OH + H_2O$, which fuses at $17^\circ C.$ ($62.6^\circ F.$).

Uses.—Phenol, in the liquid form, is locally, powerfully irritant and anæsthetic, and, applied undiluted to the skin, causes a sharp pain followed by numbness, and accompanied with a whiteness of the surface, due to the coagulation of albumin. In contact with mucous surfaces it acts in the same way, and if continued long enough may produce a superficial caustic effect. When applied externally or taken internally with sufficient freedom it is a most fatal, rapidly acting poison. The symptoms are usually developed very rapidly; indeed, death has occurred in two or three minutes, the patient dying in immediate coma and collapse. After small amounts the symptoms, which may be delayed for several minutes, are nausea, cold sweats, marked pallor of the skin, stupor rapidly deepening into complete insensibility, a feeble pulse, which is usually rapid, but has been in some cases much slower than normal, and great disturbance of the breathing. The respirations are usually hurried and shallow, often very irregular, sometimes paroxysmally arrested. There is usually paralysis both of sensation and motion, but in some cases violent epileptiform convulsions have occurred. An almost diagnostic symptom is a blackish coloration of the urine. In severe poisoning the

latter fluid is likely to contain both albumin and tube casts. Half an ounce of phenol has caused death, and recovery has been known after one and a half ounces have been taken. When phenol is employed externally the symptoms develop slowly; the dark discoloration of the urine is especially marked, and its presence should be the signal for disuse of the remedy. Death is generally due to paralysis of the respiratory centres, although the heart is powerfully depressed and death may happen by syncope; indeed, phenol is an overpowering, paralyzing poison to all higher tissues. The lesions found after death have been whitish or blackish corrugated spots on the gastric mucous membrane, imperfect coagulability of the blood, and in some instances fatty degeneration of the hepatic cell and of the renal epithelium.

Phenol is eliminated by all the emunctories, having been found by Lemaire in the breath of animals, but especially escapes through the kidneys, chiefly as a sulpho-phenolate and glyco-uronic acid, but, after toxic doses, to some extent unchanged, and probably also in some part oxidized into hydrochinon, oxalic acid, and other educts.

The diagnosis of phenol poisoning can be made out by the odor of the breath, suddenness of the development and the peculiar characteristics of the symptoms, by the presence of the characteristic white patches on the mouth and lips, if the poison has been taken in a concentrated form, and especially by the peculiarities of the urine, if the patient lives sufficiently long.

Of the tests for phenol in cases of suspected poisoning by this substance, the three most characteristic are: the ammonia and hypochlorite test, the test with ferric chloride, and the bromine test. One part of phenol in 5000 of water may be shown by adding to the solution first about one-quarter its volume of ammonium hydroxide and then a small quantity of sodium hypochlorite solution, when a blue color will appear. One part of phenol in 3000 of water can be detected by the addition of a solution of ferric chloride, when a fine violet color will develop, although the color is often interfered with in complex liquid mixtures. The most satisfactory test is that with bromine water. A whitish precipitate of tribromphenol will form even in very dilute solutions on standing. One part in 60,000 can be detected in this way. This precipitate is insoluble in water and acid liquids, but soluble in alkalies, ether, and absolute alcohol.

The first indication in the *treatment* of phenol poisoning is washing out of the stomach. On account of the great solubility of the phenol in alcohol, this fluid should be used with the water to as large an extent as is compatible with the fear of over constitutional action from absorption. The free administration of oils which was at one time largely practiced is only of service as protecting the gastro-intestinal mucous membrane and the administra-

tion of saccharated lime is also of doubtful advantage. In 1878 Baumann and Hueter announced that it is possible by the exhibition of diluted sulphuric acid or soluble sulphate to convert phenol, not only in the gastro-intestinal tract, but also after absorption, into a harmless sulpho-phenolic acid. As the result of various researches upon this subject it appears that soluble sulphates when given either through the gastro-intestinal canal or injected hypodermically are distinctly antidotal to phenol, but that there is a limitation to their power, so that if too much of the phenol has been taken the sulphates will prove of no practical value. They should always, however, be used freely in phenol poisoning. Alcohol has very recently been highly recommended by Phelps, Fraser, and others, as an efficient antidote against phenol. It certainly is valuable in local poisoning by phenol, but there is no reason to believe that there is any chemical or physiological antagonism between it and phenol, its usefulness being due to its dissolving the poison and diluting or removing it. In all cases of local phenol poisoning the parts should be washed with diluted alcohol, but in systemic poisoning alcohol should not be relied upon solely as an antidote. Strychnine and probably digitalis appear to be the only drugs which can be of much service in combating the constitutional action of phenol, and these must be used as indicated in each case.

Even the largest therapeutic dose of phenol produces no distinct symptoms when given internally, and there is no general disease in which the drug has achieved any reputation at all except *tetanus*. In this affection from five to fifteen grains (0.32 to 1 Gm.) of the pure drug may be given in the course of twenty-four hours hypodermically in a two per cent. aqueous solution. As a local remedy phenol, given by the mouth, is useful in various conditions of nervous irritability of the gastro-intestinal mucous membrane, especially when there is imperfect digestion and consequent tendency to fermentation of the gastro-intestinal contents. In *nervous vomiting* and in *gastro-dynia* it is often serviceable in doses of from one to three grains (0.065 to 0.2 Gm.) repeated at intervals varying from fifteen minutes to an hour *pro re nata*. In *diarrhœas* of irritation as well as of relaxation it is a valuable remedy, especially when used in combination with bismuth or other remedy of that class.

Externally, phenol has been largely used as a germicide in all forms of local infection and also in surgery for the prevention of infection. There can be no doubt, however, that many deaths have been produced by this use of the drug, the fatal result having been due to absorption and consequent constitutional poisoning. Moreover, in numerous cases the local use of phenol has been followed by severe local symptoms, especially gangrene, so that care is essential. In *burns*, *irritable painful ulcerations*, and in *infected wounds* the two per cent. solution of

phenol, in oil, is often very serviceable, not only as a germicide but relieving the pain by the benumbing influence on the peripheral nerve fibres. In the treatment of *carbuncles*, *boils* and various local *inflammations* including *synovitis* even of the larger joints, and *glandular swelling*, the so-called parenchymatous injection has been practised, the 1 or 2 per cent. solution being injected deeply into the centre of the affected area. The local use of phenol and the very wide spread employment of it as a general disinfectant depends upon its poisonous effect upon the lower grades of organic life. There can be no doubt, however, that its germicidal properties have been largely over estimated. As a germicide its activity as compared with corrosive sublimate as closely as can be estimated, is as 1 is to 20, with formaldehyde (37 per cent. solution) as 1 is to 2, with chlorinated lime as 1 is to 3.5.

When employed for sanitary purposes the 5 per cent. solution should commonly be used; less than 2 per cent. is ineffective. In the cleaning of drains, sinks, pipes and in various similar uses it is preferable to corrosive sublimate because it is not so readily chemically influenced by alkalies and various substances found in organic filth. The strength of the solution of phenol to be used externally varies from 1 per cent. up to the pure phenol, according to the effect desired. The 1 per cent. solution is scarcely germicidal; it inhibits, however, the growth of pathogenic organisms, and is a stimulant, and a slight local anesthetic to the tissue upon which it is placed. Concentrated phenol is a powerful escharotic and should always be used with care, lest its effect should be too far reaching.

Various fabrics are impregnated with phenol for surgical use. *Lister's gauze* may be made by soaking a loose cotton cloth with a mixture of 5 parts rosin, 7 parts paraffin, and 1 part phenol. Bruns improves upon this, making a more flexible dressing, by dissolving 400 grammes of powdered rosin in 2 liters of alcohol, adding 40 grammes of castor oil and 100 grammes of phenol; this will impregnate 2 pounds of the gauze, which is to be dried by spreading it out in the air. (See also Lund's process, *A. J. P.*, Feb. 1874.) *Carbolized jute* may be made by Rosenwasser's process by soaking in a percolator 1 pound of jute with a solution of crystallized phenol 700 grains, paraffin 700 grains, rosin 2800 grains, petroleum benzin 3 pints. (*A. J. M. S.*, 1879, p. 458. See also *N. R.*, April 1879, and April, 1880.) For burns and scalds 1 part of phenol in 6 parts of olive oil may be applied on lint. For the dressing of cancerous and other foul ulcers, a cerate (ten grains to the ounce) may be used. There is an official ointment. A phenol paper, used in packing fresh meats, in order to preserve them, may be prepared by melting 5 parts of stearin with a gentle heat, stirring in thoroughly 2 parts of phenol, adding 5 parts of melted paraffin, stirring the

mixture till it cools, and finally melting, and applying in the usual manner to the paper in quires. (*C. D.*, Dec. 1871.)

The impure liquid phenol sold in the shops usually contains from 70 to 90 per cent. of phenol and cresols jointly (*Squibb*), and, as the latter are quite equal to the former in disinfecting power, yields, if dissolved in water in the proportion of 1 to 80 parts, a solution equivalent on the average to that produced by dissolving 1 part of the pure phenol in 100 parts of water.

Administration.—When it is desired to get an immediate action upon the stomach phenol should be given in solution; when, however, it is intended to affect the intestines, it should always be exhibited in capsules mixed with starch or other inert substance, unless it be directed to be mixed with some dry medicinal powder.

Dose, one to three grains (0.065 to 0.2 Gm.).

PHENOL LIQUEFACTUM. U. S. (*Br.*)

LIQUEFIED PHENOL

(phě'nól liq-ue-făc'tūm)

"A liquid composed of not less than 86.4 percent., by weight, of absolute Phenol [$C_6H_5OH = 93.34$], and about 13.6 percent., by weight, of water." *U. S.* "Phenol to which distilled water has been added in the proportion of ten parts by weight of the water to one hundred parts by weight of the Phenol. It is commonly termed liquefied carbohc acid." *Br.*

Acidum Carbolicum Liquefactum, Br.; Liquefied Carbohc Acid; Acidum carbolicum liquefactum, *P. G.*; Verflüssigte Karbolsäure, *G.*; Fenolo liquido, *It.*; Acido fenico liquido, *Sp.*

* "Phenol, a convenient quantity; Distilled Water, a sufficient quantity. Liquefy the Phenol by placing the unstoppered container in a water-bath, and apply heat gradually until the crystals have melted; transfer the liquid to a tared vessel and weigh; then add for each nine grammes [or 139 grains] of Phenol one gramme [or 15 grains] of Distilled Water and mix thoroughly. It should be kept in dark amber-colored, well-stoppered bottles." *U. S.*

It is officially described as "a colorless liquid, which may develop a slight reddish tint upon keeping, having a characteristic, somewhat aromatic odor, and when copiously diluted with water, a sweetish taste with a slightly burning after-taste, and, when undiluted, cauterizing and whitening the skin and mucous membrane. Specific gravity: about 1.065 at 25° C. (77° F.). Soluble in 12 parts of water at 25° C. (77° F.). Miscible with alcohol, ether, and

glycerin in all proportions. One part of Liquefied Phenol acquires a permanent cloudiness when mixed respectively with 2 parts of chloroform, 1.5 parts of benzene, 2.5 parts of carbon disulphide, 2 parts of oil of turpentine, or 2.5 parts of olive oil. Liquefied Phenol begins to crystallize when the temperature of the liquid is lowered to about 13.5° C. (56.3° F.). When heated, Liquefied Phenol begins to boil at about 115° C. (239° F.), and upon continuing the heat the boiling point rises; it should not exceed 188° C. (370.4° F.). When thus deprived of water, it should respond to the tests given under *Phenol.*" *U. S.* It is described as "a liquid at first colorless, but usually acquiring a pinkish hue. It forms a clear solution on the addition of 18 to 27 per cent. of water at 60° F. (15.5° C.). Specific gravity 1.064 to 1.069 at 60° F. (15.5° C.). Boiling point gradually rising to a temperature not higher than 359.6° F. (182° C.)." *Br.* Peter Boa prefers to replace a portion of the water used for liquefying the phenol with alcohol, and he found the following mixture to remain fluid even at a temperature of 40° F.; 100 parts of phenol, 7½ parts of water, and 2½ parts of alcohol. Two minims (0.12 Cc.) are practically equivalent to one grain of the phenol.

Dose, one to three minims (0.06 to 0.2 Cc.).

Off. Prep.—Glyceritum Phenolis, *U. S.*

PHENYLIS SALICYLAS. U. S. (*Br.*)

PHENYL SALICYLATE [*Salol*, *Pharm.* 1890]

(phě'nÿl-is sāl-i-cy'lās)

$C_{13}H_{10}O_3 = 212.47$

"The salicylic ester [$C_6H_4(OH)COOC_6H_5$ 1 : 2] of phenyl." *U. S.* "Salol, or phenyl salicylate, $C_6H_4.OH.CO.O.C_6H_5$, is prepared by the interaction of salicylic acid and phenol, or of their sodium salts with phosphoryl chloride or carbonyl chloride." *Br.*

Salol, Br., U. S. 1890; Salicylate de Phénol, *Salicylate de Phényle, Fr. Od.*; Phenylum salicylicum, *P. G.*; Phenylsalicylat, *Salicylsäurephenylester, G.*; Salolo, *It.*; Salicilato de fenol, *Sp.*

Preparation.—Phenyl salicylate was first produced by Nencki of Basel, and introduced to the medical profession by Sahli, of the same place. It is prepared by heating salicylic acid with phenol in the presence of phosphorus pentachloride or phosphorus oxychloride; the action dehydrates and withdraws the elements of water, and unites the phenyl group with the salicylic acid radical. According to Ernert, nearly the theoretical yield of phenyl salicylate may be obtained by heating salicylic acid to a temperature between 160° C. and 240° C., and preventing the access of air while water is being disengaged; it is probable that salicylic anhydride is formed, and the phenyl resulting from its decomposition combines with unaltered salicylic acid to produce phenyl salicylate.

Properties.—It is described as “a white, crystalline powder, having a faint, aromatic odor, and a slight, but characteristic taste. Soluble in 2333 parts of water, and in 5 parts of alcohol at 25° C. (77° F.); very soluble in hot alcohol, and in ether, chloroform, and fixed and volatile oils. When heated to 42° C. (107.6° F.) it melts, and at a higher temperature is consumed, leaving no weighable residue. If to the alcoholic solution be added diluted ferric chloride T.S., a violet color is produced. If 0.2 to 0.3 Gm. of Phenyl Salicylate be dissolved in a little warm sodium hydroxide T.S., and the solution be then acidified with hydrochloric acid, salicylic acid separates, and the odor of phenol is recognizable. Phenyl Salicylate should not redden moistened blue litmus paper (absence of free acids). If 1 Gm. of Phenyl Salicylate be shaken with 50 Cc. of water, the liquid filtered, and 5 drops of ferric chloride T.S., previously diluted with 20 volumes of water, be added, the filtrate should show either no color, or at most a trace (limit of uncombined phenol or salicylic acid). If portions of the same filtrate be tested separately with barium nitrate T.S. and silver nitrate T.S., they should show no turbidity (absence of sulphates and chlorides).” *U. S.* “Colorless crystals having a faint aromatic odor and very little taste. Almost insoluble in water, soluble in 10 parts of cold alcohol (90 per cent.), very soluble in boiling alcohol (90 per cent.), also soluble in one-third part of ether or chloroform, and in fixed and volatile oils. Melting point 107.6° to 109.4° F. (42° to 43° C.). An alcoholic solution gives a white precipitate with solution of bromine. A violet coloration is produced on adding a few drops of dilute test-solution of ferric chloride to the alcoholic solution. On melting together Salol and sodium hydroxide, and then acidulating with hydrochloric acid, a white precipitate is produced and phenol is evolved. Water which has been shaken with Salol should not be affected by test-solution of ferric chloride (absence of free salicylic acid), and should yield no reaction with the tests for sulphates or chlorides. The alcoholic solution of Salol should be neutral to litmus.” *Br.*

Uses.—In the small intestine phenyl salicylate is broken up by the pancreatic juice, and yields about thirty-six per cent. of phenol and sixty-four per cent. of salicylic acid. The completeness and rapidity of this action depend upon the amount of phenyl salicylate ingested and of the alkaline juice in the intestines. The change is, however, sufficient, when phenyl salicylate is freely given, for the production of salicylic acid intoxication, and for the blackening of the urine with educts from phenol. Because this change occurs in the intestines somewhat slowly, the remedy is valuable as an internal antiseptic in the treatment of typhoid fever, in fermentative dyspepsia, and in various diseases of the intestinal canal. It has been largely used in rheumatism as a

substitute for salicylic acid, but it is much less prompt and certain in its action than is that remedy. Moreover, on account of the large proportion of phenol which it contains, it is much more dangerous than the corresponding dose of salicylic acid. Hesselbach has shown that it is prone to affect the secreting structure of the kidneys, and two fatal cases of poisoning by it have been reported. (*L. L.*, May, 1891.) It is especially dangerous when the kidneys are diseased. Phenyl salicylate has also been used externally as a substitute for iodoform, and internally, according to the method of Ewald, for the purposes of gastric diagnosis. (See H. C. Wood's *Therapeutics*.)

Dose, from five to fifteen grains (0.32 to 1.0 Gm.).

PHOSPHORUS. U. S., Br.

PHOSPHORUS

(phôs'pho-rûs)

P = 30.77

“It should contain not less than 99.5 per cent. of pure Phosphorus, and be carefully kept under water, in strong, well-closed vessels, in a secure and moderately cool place, protected from light.” *U. S.* “A solid non-metallic element obtained from calcium phosphate.” *Br.*

Phosphore, *Fr. Cod.*; Phosphorus, *P. G.*; Phosphor, *G.*; Fosforo, *It.*, *Sp.*

This non-metallic element was discovered in 1669 by Brandt, an alchemist of Hamburg, who obtained it from evaporated urine by a process which remained a secret until 1737. As thus procured, it was exceedingly scarce and costly. In 1769 the Swedish chemist Gahn discovered it in bones, and shortly afterwards published a process by which it might be extracted.

Preparation.—Powdered calcined bones (calcium bone phosphate) are digested for twenty-four hours with two-thirds of their weight of sulphuric acid previously diluted with twelve times its weight of water. The sulphuric acid separates the greater part of the lime from the phosphoric acid, and precipitates as calcium sulphate, while an acid calcium phosphate, $\text{Ca H}_2(\text{PO}_4)_2$, remains in solution. The liquid is then strained through a linen cloth to separate the calcium sulphate, and afterwards submitted to evaporation, which causes a fresh precipitation of sulphate, to be separated by a new straining. The strained solution is evaporated to a syrupy consistence, and then thoroughly mixed with half its weight of powdered charcoal, so as to form a mass, which is dried by being heated to dull redness. At this temperature the acid phosphate is changed into metaphosphate, $\text{Ca}(\text{PO}_3)_2$, by the loss of two molecules of water. The mass when cool is quickly transferred to a coated earthenware

retort, furnished with an adapter of copper, bent downward at right angles, so as to enter a bottle with a large neck containing water, which should rise about two lines above the orifice of the adapter. The bottle is closed round the adapter with a cork, which is traversed by a small glass tube, to give exit to the gaseous products. The retort is heated in a furnace, furnished with a dome, in the most gradual manner, so as to occupy about four hours in bringing it to a red heat. Afterwards the heat is pushed vigorously, so long as any phosphorus drops into the water, and this takes place generally for from twenty-four to thirty hours. During this part of the process the metaphosphate is decomposed, its oxygen combining with the charcoal, and the liberated phosphorus distilling over. The calcined bones of the sheep are preferred, as they contain the largest proportion of calcium phosphate and are most readily acted on by the acid. In the process as described, only two-thirds of the phosphorus is set free, the remainder being still combined. If, however, silica is added to the mixture before the distillation, all the phosphorus is liberated.

The electrolytic phosphorus process, first brought out by Readman and Parker some years ago, has now practically displaced the older methods for the production of phosphorus. Albright & Wilson, who formerly manufactured phosphorus by the distillation method at Oldbury, England, have built works at Niagara Falls, and practically control the production by the electrolytic method in the United States and England.

A mixture of calcium phosphate, carbon, and sand or kaolin is submitted to the temperature of the electric arc while packed in a covered plumbago crucible. The phosphorus is then distilled off in a current of an inert gas. It is very pure, and it is claimed that 86 per cent. is recovered. The native Redonda phosphate, an aluminum phosphate, is also taken for this process instead of the calcium phosphate, and phosphorus obtained from it without any previous purification. The great bulk of the phosphorus is consumed in the manufacture of matches, a smaller amount in the production of phosphor bronze, and another portion in making the chemical compounds of the element. The present annual production (1906) is about 3000 tons, produced in three factories: Oldbury in England, Lyons in France, and Niagara Falls in the United States.

Properties.—Phosphorus is a semi-transparent solid, without taste, but possessing an alliaceous odor. When perfectly pure it is colorless, but as usually prepared it is yellowish or reddish-yellow. It is flexible, and when cut exhibits a waxy lustre. It was said by Boettger to be easily pulverizable by agitation with a solution of urea. (*J. P. C.*, Juin, 1863, p. 488.) "A translucent, nearly colorless solid, of a waxy lustre, having, at ordinary temperatures, about the consistency of beeswax. By long

keeping, the surface becomes white or red, and occasionally black. It has a distinctive and disagreeable odor and taste (*but should not be tasted, except in very dilute solution*). When exposed to the air, it emits white fumes, which are luminous in the dark, and have an odor somewhat resembling that of garlic; on longer exposure to air, it often takes fire spontaneously. Specific gravity: 1.830 at 10° C. (50° F.), and 1.820 at 25° C. (77° F.). Melting point: 44° C. (111.2° F.). Phosphorus is insoluble, or nearly so, in water, to which, however, it imparts its characteristic, disagreeable odor and taste; soluble in 350 parts of absolute alcohol at 15° C. (59° F.), in 240 parts of boiling absolute alcohol, in 80 parts of absolute ether, in about 50 parts of any fatty oil, and in about 25 parts of chloroform; it is very soluble in carbon disulphide,¹ the latter yielding a solution which must be handled with the greatest care to prevent evaporation, which would be followed by instant ignition. To test for *arsenic* and *sulphur* proceed as follows: Add 1 Gm. of Phosphorus to 10 Cc. of nitric acid diluted with 10 Cc. of distilled water, in a flask having a capacity of 50 Cc., and digest the mixture at a gentle heat on a water-bath while passing a current of carbonic acid gas into the flask over the surface of the liquid until the Phosphorus is dissolved. Transfer the solution to a dish, and evaporate it until no more nitrous vapors are given off, and then dilute the solution to 100 Cc. with distilled water. One Cc. of this solution should not respond to the Modified Gutzeit's Test for *arsenic* (see PART III, Test No. 17). On adding barium chloride T.S. to the remainder of the liquid, not more than a slight opalescence should be produced (limit of *sulphur*)." *U. S.* "Specific gravity 1.77. It is soft and flexible at common temperatures, melts at 110° F. (43.3° C.), ignites in the air at a temperature a little above its melting point, burns with a luminous flame, and produces dense white fumes. It is insoluble in *water*, but soluble in 350 parts of *absolute alcohol*, in 80 parts of *olive oil*, in 80 parts of *ether*, in 25 parts of *chloroform*, in half its weight of *carbon bisulphide*, and in boiling *oil of turpentine*. 1 or 2 grammes should be attacked slowly and be dissolved without residue on being boiled with 5 or 10 cubic centimetres of *nitric acid* diluted with an equal volume of *water*, and the resulting solution should yield no characteristic reaction with the tests for arsenium, and only the slightest reactions with the tests for sulphates." *Br.* Its pulverization may be readily effected by melting it in hot water, and agitating until it is thoroughly cooled, and the powder is obtained finer in saline solutions than in pure water.

Phosphorus boils at 287.7° C. (550° F.), air being excluded. During its combus-

¹ According to Flückiger, carbon disulphide is capable of dissolving twenty times its weight of phosphorus without losing its fluidity.

tion it combines with the oxygen of the air, and forms phosphoric oxide. On account of its great inflammability, it must be kept under water. When exposed to the air it undergoes a slow combustion, emitting white vapors, which are luminous in the dark. It sometimes contains arsenic, and therefore, when used in forming medicinal preparations, should be tested for that metal. C. J. Rademaker obtained out of 100 parts of phosphorus about one part of arsenic. (A. J. P., Nov. 1870.) It occasionally contains antimony or sulphur, the latter rendering it brittle.

When phosphorus is kept in ordinary water it becomes covered with a whitish layer, of the nature of which there are different opinions, it being looked upon by some as a phosphorus hydrate, by others as an allotropic condition of that element, and by others again as a partial crystallization, but all these opinions have apparently been disproved by Ernest Baudrimont, who seems to have demonstrated that *white phosphorus* is entirely identical with that principle in its ordinary state, and results from a kind of erosion of the surface, owing to partial oxidation by the free oxygen held in solution by the water. The change never takes place in water entirely deprived of air, and the water when it has taken place holds phosphorous acid in solution. (J. P. C., 4e sér., iii. 17, 1866.)

Schroetter of Vienna, discovered an allotropic form of phosphorus, which he called *red* or *amorphous phosphorus*.¹ It is formed when ordinary phosphorus is kept long at a temperature between 215° C. (419° F.) and 250° C. (482° F.), in atmospheres which have no action on it, or in closed glass tubes. Red phosphorus is much more indifferent than the ordinary substance, and is denser, its sp. gr. being 2.11. It is much less easily acted on by the air than ordinary phosphorus, and is insoluble in carbon disulphide, alcohol, and ether, in all of which ordinary phosphorus is soluble. Solidified from the fused state, it is brittle, and breaks with a conchoidal fracture. Its hardness is considerable. Obtained by distillation in a non-acting gas, it is mixed with ordinary phosphorus, from which it may be freed by carbon disulphide, which dissolves the ordinary variety and leaves the allotropic as a deep red amorphous powder. It may also be purified by shaking it with a solution of calcium chloride of a density intermediate between that

of red and that of ordinary phosphorus, and with a little carbon disulphide. The red variety will sink to the bottom, and the ordinary float on top of the solution, dissolved in the disulphide. (E. Nicklés.) Red phosphorus when pure is not poisonous. This has been proved beyond a doubt by the experiments of Reynal and Lassaigne and of L. Orfila and Rigaut. It is applicable to the manufacture of lucifer matches, and forms a much safer material than ordinary phosphorus. It does not take fire by friction at common temperatures, and therefore may be transported with the greatest safety. It has been said to be unchangeable in the air but this is not exactly true, as proved by an observation of T. B. Groves, who, having set aside some red phosphorus in a bottle that was not air tight observed for a year or more no visible change, but found at length that it had become decidedly altered, and ascertained that oxidation had taken place, with the result of forming a large quantity of phosphoric and phosphorous acids, in the proportion of 5 molecules of the former to 2 of the latter. (P. J., June, 1865, p. 621.) Besides the white and red forms of phosphorus, there is another, called the *black*, first noticed by Thénard and investigated by Blondlot, who found that it is pure phosphorus, and that its production is owing to some modification in the mode of cooling, when it has been in the liquid state. (J. P. C., 4e sér., i. 407, 1865.) Flückiger doubted the existence of black phosphorus, however, and, after an investigation, states that the black color is due to arsenical contamination. (Chem. Ztg., 1892, 181.)

Still another modification of phosphorus has been made known by Hittorf, who obtained it by heating red phosphorus and lead together in a closed vessel. The lead on melting dissolved the phosphorus, and on cooling deposited it in the state of black crystals resembling the crystals of arsenic. In this form, phosphorus is a conductor of electricity, and its sp. gr. at 16.6° C. (62° F.) is 2.34. Hittorf distinguishes it by the name of *metallic phosphorus*, and ranks it in the same category with red phosphorus, the latter differing simply in being amorphous. (Chem. News, March 23, 1866, p. 133.) Blondlot has succeeded in crystallizing common phosphorus by means of sublimation, operating in an atmosphere of nitrogen. (J. P. C., 4e sér., iv. 321.)

Phosphorus forms with oxygen two oxides, *phosphoric*, P_2O_5 , and *phosphorous*, P_2O_3 . Corresponding to the first of these are three acids, known as *orthophosphoric* (tribasic phosphoric), H_3PO_4 , *pyrophosphoric*, $H_4P_2O_7$, and *metaphosphoric*, HPO_3 . The first of these is formed by dissolving P_2O_5 in boiling water, or by the action of nitric acid upon phosphorus itself; the second by the heating of the tribasic phosphoric acid to 213° C. (415.4° F.); and the third by the ignition of the tribasic variety, or by dissolving P_2O_5 in cold water. To the second oxide corresponds *phosphorous*

¹ E. Q. Thornton proposes the use of the *red amorphous phosphorus* as a safe substitute for phosphorus in medicine. In his own experiments upon animals he found that in large quantities it is non-toxic, but asserts that after its administration in increasing doses until three-tenths of a grain were taken every two hours (nine doses a day), it produced mental excitement, headache, vertigo, priapism, and nocturnal emissions, followed about the twentieth day by nervous exhaustion, with return to health in about two weeks after the discontinuance of the drug. It is obvious that the red phosphorus is physiologically very different from the ordinary form of the element; whether it may prove to be a useful stimulant in cases of sexual and other forms of exhaustion is not evident.

acid, H_3PO_3 , although it cannot be formed directly from the oxide. This is a dibasic acid, containing one hydrogen atom not replaceable by metal. To the hypothetical *hypophosphorous oxide*, P_2O , corresponds *hypophosphorous acid*, H_3PO_2 . It is monobasic, containing two hydrogen atoms not replaceable by metal.

Uses.—Phosphorus, when given in small doses, is believed by some to act as a general stimulant. With more probability it is believed by most neurologists to act as a nutritive stimulant to the nervous system. Its usefulness in *sexual exhaustion*, in failure of the mental powers from similar causes, and indeed in all forms of exhaustion of the nerve centres, when no organic lesion has occurred, seems unquestionable, and it may even be used, with hope of advantage, in *cerebral softening*. It is sometimes of service in *neuralgia*, and has been employed with asserted advantage in *mania*, in *melancholia*, and in *chronic eczema*, *psoriasis*, and other *affections of the skin*. When taken in large doses it is a deadly poison. The symptoms usually do not manifest themselves until some hours after the ingestion of the phosphorus. General malaise then becomes very pronounced, and is soon accompanied by nausea, abdominal pain, and vomiting of food, mucus, and bile. On the second and third day the vomiting is likely to cease, but the abdominal tenderness remains, and there is some fever. Jaundice also sets in, both the conjunctiva and the urine betraying its onset. The yellow color rapidly involves the whole surface. Early in the poisoning there is often great anxiety, restlessness, headache, and giddiness, but now delirium appears, wild, erotic, or low and muttering. Severe vomiting of a coffee-ground liquid, free from bile and similar to the black vomit of yellow fever, is now present; the urine is scanty and albuminous, often with tyrosine and leucine in it, or it may finally be suppressed. The temperature falls markedly, and the patient sinks into a coma which ends in death. After death a peculiar fatty degeneration is found affecting almost all the soft tissues. The parts which suffer first are the liver, the gastro-intestinal mucous membrane, and the kidneys. Very often the heart muscle is also disorganized. The liver is always yellow, its cells engorged with fat globules. At first it undergoes decided enlargement, but if the patient live long enough it atrophies. Both in its symptoms and in its lesions phosphorus poisoning so closely resembles acute atrophy of the liver that only by detecting the phosphorus in the matters vomited, in the excretions, or in the tissues of the body, can a positive diagnosis be made. M. Poulet (*G. M. P.*, Aug. 1872) states that hypophosphorous acid can be detected in the urine by heating the latter with nitric acid to dryness; if the acid be present, as the latter condition is approached there will be a sudden outburst of flame.

E. Mitscherlich gave the following as a delicate test for phosphorus. The suspected substance is distilled with sulphuric acid and water from a flask, by means of a tube bent twice at right angles, into a vertical cooling-tube, passing through the bottom of a wide glass cylinder filled with water, which is constantly kept cold by passing cold water in at the bottom, while the warm water escapes at the top. Under the cooling-tube is placed a vessel to receive the distillate. If phosphorus is present, its vapor, mixed with steam, distills over, and gives rise to a distinct luminous appearance, visible in the dark, at the point where it enters the cold part of the cooling-tube. The presence of alcohol and ether prevents the occurrence of the luminous appearance until they have distilled over. Oil of turpentine has the same effect permanently, but is not likely to be present in medico-legal cases. Mitscherlich's test acts equally well in the presence of fatty matters, as has been shown by de Vrij. Roussin finds that the presence of free butyric acid prevents the luminous appearance of the phosphorus. After neutralizing with potassium carbonate, however, it can be seen. (Sonenschein, *Gerichtl. Chem.*, 1881, p. 27.) L. Hofmann gives the following method of detecting phosphorus in the viscera in cases of poisoning. The viscera, mixed with water and a little sulphuric acid, are distilled until two drachms of liquid are obtained; to this a few drops of ammonium sulphide (ammonium sulphhydrate) are to be added, and the liquid is to be evaporated to dryness in a porcelain dish. If phosphorus be present in the minutest quantity, a drop of solution of ferric chloride will produce a deep violet and brownish, though evanescent, color. (*Chem. News*, Feb. 3, 1865, p. 53.) In addition to Mitscherlich's test, Dusart's is also used. This consists in passing pure hydrogen gas, evolved in a separate vessel, through the solution supposed to contain phosphorus, which solution has been previously warmed to about 50°C . The gas then is allowed to issue from a fine jet and is lighted. If phosphorus be present, the flame will show a green color in the centre.

The treatment of phosphorus poisoning consists simply in administering the antidotes as soon as possible. Oil of turpentine was originally proposed by Andant. After much discussion, it has been finally determined that, while the pure oil has no effect upon phosphorus, the acid French oil of European commerce forms with it a crystalline, spermaceti-like mass. This is soluble in ether, alcohol, and alkaline solutions, and has received the name of *turpentine-phosphoric acid*. It is said to be eliminated by the kidneys unchanged, and to exert no deleterious influence. Köhler asserts that when German oil has not been rectified for some time it acts upon phosphorus. He believes that the oil acts partly by oxidizing the poison, and partly by converting it into the harmless turpentine-phosphoric acid. One

part of the oil must be given for 0.01 part of the phosphorus. The ordinary American oil of turpentine, as well as Canada balsam, appears to be of no antidotal value in phosphorus poisoning.

As was pointed out by Eulenberg and Guttman, phosphorus in a solution of a soluble salt of copper becomes black immediately, owing to the formation of a phosphide of the metal. Bamberger asserts that, while this change is very rapid, that induced by turpentine is a slow one, and, from an elaborate series of experiments upon animals, he concludes that copper is much the more valuable and certain antidote. Antal found potassium permanganate an antidote in acute poisoning by phosphorus. Hajinos has successfully washed out the stomach, half an hour after the ingestion of the poison, with a pint of a one-tenth per cent. solution of the permanganate. (*Notes on New Remedies*, July, 1892.)

In human poisoning, copper sulphate should be given in dilute solution, three grains (0.20 Gm.) every five minutes until vomiting is induced. After this, if the French oil be accessible, it may be given freely in emulsion, or, probably better, a solution of potassium permanganate may be administered. Magnesium sulphate or citrate should be used as a quickly acting purge, and symptoms met as they arise.

In dogs poisoned by phosphorus, L. Orfila and Rigaut have shown that putrefaction was remarkably retarded. In a case of chronic poisoning from the copious inhalation of phosphorus vapor, the principal results were a gradual decay of the sexual function, and paralysis, terminating in death at the end of three years. Partial or general paralysis is a not uncommon result. (*L. L.*, July 7, 1866, 23.)

Dose, of phosphorus, from 1-100th to 1-80th of a grain (0.0006 to 0.0008 Gm.). Much larger doses than these have been given, but have in various cases produced unpleasant symptoms. The *elixir* (*Elixir Phosphori*, U. S. 1890) is probably the most eligible of the liquid preparations, but the *oil* (*Oleum Phosphoratum*, U. S. 1890) is very efficient, as is also the official pill (*Pilule Phosphori*). Great caution is necessary in the exhibition of phosphorus, and its effects should be closely watched. It ought never to be given in substance.¹

Off. Prep.—*Oleum Phosphoratum*, Br.; *Pilule Phosphori*, U. S. (Br.).

¹*J. Ashburton Thompson's Solution of Phosphorus.* Take of phosphorus, one grain (0.065 Gm.); absolute alcohol, five fluidrachms (18.4 Cc.). Dissolve the former in the latter by gentle heat, and add to it a previously warmed mixture of one and a half fluidounces (44.2 Cc.) of glycerin, two fluidrachms (7.4 Cc.) of alcohol, and forty minims (2.5 Cc.) of spirit of peppermint. One fluidrachm (3.75 Cc.) of this solution contains one-twentieth of a grain (0.003 Gm.) of phosphorus.

Tinctura Phosphori (*Bellevue Hospital*).—Take of clean, transparent phosphorus, thirty-two grains (2.07 Gm.); absolute alcohol, forty-six fluidounces (1360 Cc.). Digest the phosphorus in the alcohol

PHYSOSTIGMA. U. S. (Br.)

PHYSOSTIGMA [Calabar Bean]

(phÿ-sq-stig'mă)

"The ripe seed of *Physostigma venenosum* Balfour (Fam. *Leguminosæ*), yielding, when

on a water bath in a flask provided with a reflux condenser, until solution has taken place. Allow the solution to cool, and add to it one fluidounce (29.5 Cc.) of essence of vanilla, and three fluidrachms (11 Cc.) of oil of orange. Finally, make up the bulk with absolute alcohol to forty-eight fluidounces (1416 Cc.). Twelve fluidrachms (44.2 Cc.) of this solution contain one grain (0.065 Gm.) of phosphorus. (*N. R.*, April, 1876.)

Phosphorus Paste, for the destruction of vermin, is made as follows. Triturate six parts of phosphorus and one part of sulphur with six parts of water, until they liquefy. Then mix in two parts of flour of mustard, eight parts of sugar, and twelve parts of rye flour, with the aid of ten additional parts of water, and stir the whole so as to form a soft paste, which must be kept in pots closely stoppered. (*A. J. P.*, 1855, p. 473.)

Resina Phosphorata, Phosphorated Rosin, Phosphoretted Resin.—Melt together, by the aid of a sand bath, in a dry bottle having nearly the exact capacity of the ingredients, rosin free from moisture 96 parts and phosphorus 4 parts. Keep the whole at a temperature of 392° F. until the Phosphorus is dissolved, cool, and keep in bottles protected from light.

H. A. B. Dunning (*Proc. A. Ph. A.*, 1902, 573) furnishes the following process:

Phosphorus Rosin.—Oil of sweet almond, 1 part; Rosin, 8 parts; Yellow wax, 2 parts. Melt the rosin by the aid of direct heat, add the yellow wax and remove from the fire, add the oil. Strain sufficient of the mixture, while stirring into a strong wide-mouthed bottle of such size as to prevent it being more than three parts full, and then allow it to become cool. Weigh the phosphorus, four or ten per cent., under water, dry with filter paper and drop into the bottle containing the cold rosin mixture, then quickly cork and tie down with twine. Place the bottle in a water bath, so that it will not rest directly upon the bottom, and heat the water gradually to boiling. Continue the boiling until the contents are quite fluid. Now shake the bottle until the phosphorus is thoroughly distributed; continue the shaking until the contents of the bottle become too viscous to shake. After the finished product has become entirely cold, the bottle is to be broken, the mass freed from adhering glass, cut into small pieces, placed in a stock bottle and covered with water to prevent oxidation. The quantity representing the amount of phosphorus desired can be easily and carefully weighed without loss of phosphorus, and may be incorporated into pill masses with ease and certainty, as substances of like physical character are usually incorporated.

Spiritus Phosphori, U. S. 1890, *Spirit of Phosphorus* (*Tincture of Phosphorus*).—"Phosphorus, one and two-tenths grammes (or 18½ grains); Absolute Alcohol, a sufficient quantity, to make one thousand cubic centimeters (or 33 fluidounces, 6½ fluidrachms). Weigh the Phosphorus in a tared capsule containing water, then dry it carefully and quickly with blotting paper, and introduce it into a flask containing one thousand cubic centimeters (or 33 fluidounces, 6½ fluidrachms) of Absolute Alcohol. Connect the flask with an upright condenser supplied with cold water, and apply the heat of the water-bath, so that the Alcohol may be kept gently boiling, until the phosphorus is dissolved. Then allow the liquid to become cold, and, if necessary, add to it enough Absolute Alcohol to make it measure one thousand cubic centimeters (or 33 fluidounces, 6½ fluidrachms). Lastly, transfer the Spirit to small, dark amber-colored vials, which should be securely stoppered, and kept in a cool and dark place." U. S. 1890. This is the basis of the *Elixir of Phosphorus*, U. S. 1890, and is rarely directly used in medicine. It should be freshly prepared, as it is not a stable preparation. Each fluidrachm (3.75 Cc.) contains about one-fifteenth grain of phosphorus.

Elixir Phosphori, U. S. 1890, *Elixir of Phosphorus*.—"Spirit of Phosphorus, two hundred and ten cubic centimeters (or 7 fluidounces, 48 minims); Oil of Anise, two cubic centimeters (or 32 minims); Glycerin, five hundred and fifty cubic centimeters (or 18 fluidounces, 287 minims); Aromatic Elixir, a sufficient quantity, to make one thousand cubic centimeters (or

assayed by the process given below, not less than 0.15 percent. of alkaloids soluble in ether." *U. S.* "The ripe seeds of *Physostigma venenosum*, Balfour." *Br.*

Physostigma venenosum, Balfour, *Trans. Roy. Soc. Edinb.*, xxii. 305; *Ed. Med. Journ.*, July, 1863, p. 34; *B. & T.* 80.—This is a climbing plant, with a ligneous stem, mounting on trees and shrubs, and frequenting especially the banks of streams, into which it often drops its fruit when ripe, and it is said that the people of Calabar derive their supply principally from the borders of the streams down which the fruits are carried. The root is spreading, with numerous fibrils, often having attached to them small succulent tubers. The flowers are in axillary, multiflorous, pendulous racemes. The corolla is papilionaceous, of a pale pink color, with a purplish tinge. The legume when ripe is about seven inches long, and contains two or three seeds. It ripens at all seasons, but is most abundant during the rainy season from June to September. The seeds are the part used. The plant, which is indigenous to Western Africa, has been introduced into India and Brazil, and is said to flourish in the latter country. Only one other species (*P. mesoponticum*, Taub.), also of tropical Africa, is known. For a paper on the botanical description, history, etc., of *Physostigma venenosum* by J. U. Lloyd see *West. Drug.*, 1897, 249.

This bean was brought to the notice of the scientific public by Daniell, in 1846. Considerable attention was attracted to the subject, and specimens of the bean were obtained by Christison from the Gold Coast. These were planted in the Botanical Garden at Edinburgh, and produced a perennial creeper. In the year 1859, specimens of the plant were sent from Calabar, which came under the observation of Balfour of Edinburgh, who was thus enabled to ascertain its botanical character.

Properties.—The seed is about the size of a large horse-bean, being somewhat more than an inch in length by three-fourths of an inch in breadth, with a very firm, hard, brittle, shining integument of a brownish-red, pale chocolate, or ash-gray color. The shape is irregularly kidney-form, with a longer convex

and a shorter concave edge, two flat sides, and a furrow running longitudinally along its convex margin and ending in an aperture near one of the extremities of the seed. Within the shell is a kernel consisting of two cotyledons, weighing on an average about 46 grains, hard, white, pulverizable, odorless, and having a taste like that of the ordinary edible leguminous seeds, without bitterness, acrimony, or aromatic flavor. "Oblong, somewhat reniform, 15 to 30 Mm. long, 10 to 15 Mm. thick; externally reddish- or chocolate-brown, smooth, somewhat roughened near the brownish-black groove which extends almost the entire length of the convex edge, its reddish, rounded margins elevated and somewhat thickened; embryo whitish, with a short, curved hypocotyl and two large, concavo-convex cotyledons; having a bean-like and heavy odor when crushed; taste at first starchy, afterwards acid." *U. S.* The bean yields its virtues to alcohol, and imperfectly to water. The shell constitutes, according to Edwards, 30 per cent., the kernel 70 per cent., of the bean. Jobst and Hesse (*J. P. C.*, Mars, 1864, p. 277) first isolated an active principle, which they found exclusively in the cotyledons. They obtained it by exhausting an alcoholic extract of the seeds with water, adding magnesia to neutralization, which is indicated by the liquid becoming brown, then concentrating, and treating with ether. The ethereal solution was shaken with a little weak sulphuric acid. The liquid separated into two layers,—the upper, ethereal, containing no alkaloid, and the lower, a solution of the sulphate in water. The latter was separated, treated with magnesia, and afterwards with ether, which yielded the alkaloid on evaporation. The substance thus obtained they proposed to name *physostigmine*. It was amorphous, soluble in ammonia, sodium hydroxide, ether, benzene, and alcohol, and less so in cold water. In 1867, Hesse (*Ann. Ch. Ph.*, 141, 82) obtained the same alkaloid in a still purer state, perfectly colorless and tasteless, fusing at 45° C. (113° F.), and decomposing at 100° C. (212° F.) with red coloration. He gives it the formula $C_{15}H_{21}NO_2$. In 1865 Vée and Leven (*C. R. A. S.*, 60, 1194) obtained, by treating the seeds in nearly the same manner, an alkaloid to which they gave the name *eserine*, which formed colorless tabular crystals of a bitter taste, readily soluble in ether, alcohol, or chloroform, but sparingly in water. The crystals contain 1 molecule of water, which they lose at 100° C., and the anhydrous alkaloid then fuses at from 102° to 103° C. The identity of this principle with the *physostigmine* of Hesse is now generally accepted. The solution of *eserine* acts quickly on the pupil, and a drop of a solution containing only 1 part in 1000, placed within the eyelids, causes great and lasting contraction. Of this alkaloid 1.5 milligrammes (1-40th gr.) injected under the skin of a guinea pig produced palsy of the hind legs in five minutes, and death in half

33 fluidounces, 6½ fluidrachms]. To the Spirit of Phosphorus, contained in a graduated bottle, add the Oil of Anise and Glycerin, and mix them by repeatedly inverting the bottle, until they form a clear liquid. Then add Aromatic Elixir, in several portions, gently agitating after each addition, until a transparent liquid is obtained, and the product measures one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Keep the product in dark amber-colored, well-stoppered bottles, in a cool and dark place." *U. S.*

Each cubic centimeter of this preparation represents about one-fourth milligramme (0.00025 Gm., or 1-260th grain) of phosphorus. A teaspoonful of the recently made elixir contains about 1-65th grain (0.001 Gm.) of phosphorus.

Dose, from twenty to sixty minims (1.3 to 3.9 Cc.).

an hour, with dilatation of the pupil at the moment of death. It is said to be capable of destroying life by absorption from the conjunctiva. A peculiarity of the alkaloid is that an aqueous solution of it, or of one of its salts, exposed to the air in the presence of potassium or sodium hydroxides, or lime, becomes red, owing to the absorption of oxygen. The coloring matter is taken up by chloroform. The color is not permanent, but gradually changes to yellow, green, or blue. This test will detect less than the hundred-thousandth part of the alkaloid. The same property is possessed by the alcoholic extract of the bean. Physostigmine was official in the Br. Pharm. 1885, and was thus described: "In colorless or pinkish crystals, slightly soluble in water, but readily soluble in alcohol and in diluted acids. The aqueous solution has an alkaline reaction, when warmed with or when shaken with dilute solution of potash becomes red, and when evaporated to dryness over a water bath leaves a bluish residue, the acidified solution of which is beautifully dichroic, being blue and red." Br. 1885. The percentage of physostigmine in Calabar bean forms the basis of the assay of the U. S. P. (8th Rev.). It is as follows:

Assay. U. S. (8th Rev.).—"Physostigma, in No. 60 powder, twenty grammes; Ether, Solution of Sodium Bicarbonate (1 in 20), Normal Sulphuric Acid V.S., Tenth-normal Sulphuric Acid V.S., Fiftieth-normal Potassium Hydroxide V.S., Distilled Water, Iodeosin T.S., each, a sufficient quantity. Introduce the Physostigma into a Erlenmeyer flask of about 250 Cc. capacity, add 200 Cc. of ether, and shake the flask well during ten minutes. Then add 10 Cc. of an aqueous solution of sodium bicarbonate (1 in 20), and shake the mixture vigorously at intervals during four hours. Allow the powder to settle, and decant 100 Cc. of the ether-solution (representing 10 Gm. of Physostigma) into a measuring cylinder; then transfer it to a separator, introduce a small piece of blue litmus paper, and add sufficient normal sulphuric acid V.S. to render the liquid acid, and then 10 Cc. of distilled water. Shake the liquid well for several minutes, and draw off the aqueous layer into another separator. Repeat the extraction, using 2 Cc. of normal sulphuric acid V.S. and 8 Cc. of distilled water, add the acid aqueous layer to the second separator, and finally again shake out the ether solution, using 1 Cc. of normal sulphuric acid V.S. and 9 Cc. of distilled water, adding this also to the second separator. To the combined acid liquids in the second separator, add 25 Cc. of ether, a small piece of red litmus paper, and sufficient sodium bicarbonate solution (1 in 20) to render it alkaline. Shake the separator for one minute, allow the liquids to separate, and draw off the ether into a beaker. Repeat the shaking out process with 20 Cc. and again with 15 Cc. of ether added to the separator, shake each time for one minute, allow the liquids to sepa-

rate, and draw off the ether into the beaker. Carefully evaporate the ether from the combined solutions by means of a water-bath, and when dry, dissolve the residue in 5 Cc. of tenth-normal sulphuric acid V.S. and 20 Cc. of ether, which must be strictly neutral, and transfer this solution to a bottle, rinsing with 80 Cc. of water; add 5 drops of iodeosin T.S., and titrate the excess of acid with fiftieth-normal potassium hydroxide V.S., until, after shaking, the aqueous liquid just acquires a pink color. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract the quotient from 5 (the 5 Cc. of tenth-normal sulphuric acid V.S. taken) and multiply the remainder by 0.0273, and this product by 10; the result will be the percentage of alkaloids soluble in ether contained in the Physostigma. The figure 0.0273 represents the weight in grammes of alkaloids (mainly physostigmine) required to neutralize 1 Cc. of tenth-normal sulphuric acid V.S." U. S.

Harnack and Witkowski, A. E. P. P., v.; also x., in 1876 obtained still another alkaloid, which they named *calabarine*. It is soluble in alcohol and water, nearly insoluble in ether, melts at 132° C., and differs in physiological character from physostigmine. It is now generally known under the name of *eseridine*.¹ The formula $C_{15}H_{23}N_3O_3$ has been given to it, which differs from that of physostigmine, it will be seen, by H_2O only, and it is stated that the one can be changed into the other by the action of dilute acids. There is much reason for believing that calabarine is a decomposition product derived from physostigmine. (Husemann, A. E. P. P., 1878, 14; Harnack, A. E. P. P., x.)

Hesse obtained also a neutral fatty body, *phytosterin*, by exhausting the cotyledons with petroleum benzin. It is closely allied to cholesterol, but its chloroform solution is devoid of rotatory power. Its formula is $C_{25}H_{44}O + H_2O$, and its melting point is 133° C. (271.4° F.).

Uses.—Calabar bean has been used from time immemorial by the natives of Africa as an ordeal, and, when given by their head men, usually proves fatal to the accused, unless free vomiting occurs. A draught containing 19 seeds pounded and infused in water is said to have killed a man in an hour. In the experiments of Fraser, it was found that the integuments of the seeds, as well as the shell, are distinctly purgative. It is probable that in the fresh bean they are also emetic, and that the priests or chiefs who administer the ordeal take advantage of this in regulating the

¹ According to its discoverer (D. M. Ztg., Dec. 1889), eseridine is a tetanizant; it has also been affirmed to cause elevation of the blood pressure and slowness of the pulse, followed by progressive paralysis and death from failure of the respiration, and to markedly increase internal peristalsis and to produce watery purging. It has been recommended by Eber, also by Ostertag (B. Thier. W., Jhrg. 4, 5, Nos. 40, 43), as a laxative in veterinary medicine, but has not been used to any extent for human beings. As a poison it is said to have one-sixth the strength of *eserine*.

effects of the poison to suit their own purposes; sometimes, however, even the pure alkaloid causes vomiting. (Gubler.) Christison took about 12 grains of the kernel, which in fifteen minutes produced giddiness and a feeling of torpidity, followed by great weakness and faintness, paleness of the surface, extreme weakness and irregularity of the pulse, and indisposition or inability to make voluntary muscular effort. A peculiar epigastric sensation is often the first symptom of the action of the poison, and sometimes becomes severe. The heart often acts tumultuously or irregularly, but the pulse frequency may be reduced. Of seventy children poisoned in Liverpool by eating Calabar beans which had been thrown upon a waste heap, vomiting occurred, or was produced by emetics, in all except one, in whom four kernels caused death. The nausea and vomiting came on in about half an hour, the nervous symptoms in less than an hour.

In the lower animals Calabar bean produces muscular tremors, diminished reflex activity, contractions of the pupils, some cardiac disturbance, and a progressive paralysis ending in death from paralytic asphyxia. It has been proved by Fraser that the paralysis is due to a depressant action upon the motor tract of the spinal cord, this being the most important physiological effect of the drug. The brain, the sensory tract of the cord, and the nerve trunks are not affected, but the muscles are directly influenced; hence the muscular twitchings. Small doses somewhat increase the force but diminish the frequency of the heart beat, and cause rise of arterial pressure. Toxic doses depress the heart and lower arterial pressure. The intestinal peristalsis, and probably also the bronchial movements, are primarily increased, and, after a toxic dose, secondarily diminished. Locally applied to the eye, Calabar bean causes myosis, with disturbance of accommodation. A similar effect is usually produced by large doses taken internally; it is largely the result of a local paralysis of the peripheral sympathetic fibres in the eye, but it is probable that there is also stimulation of the oculomotor nerve terminations. The sedative influence of Calabar bean upon the motor spinal tract early led to its use in *tetanus*, *strychnine poisoning*, and similar conditions of spinal excitement. Clinical experience has, however, shown that it is of less value than chloral or some other depressant motors, so that it is chiefly employed as a succedaneum for these remedies. The effect of the drug upon intestinal peristalsis has led to its use in "*phantom tumor*" of the abdomen, *constipation*, and other affections of the bowels dependent upon muscular atony. It has also been employed with great asserted advantage in *chronic bronchitis*.

In Calabar bean poisoning the stomach should be thoroughly washed out, and atropine, which has been found by Kleinwächter, Bourneville, and Fraser to be physiologically antago-

nistic to Calabar bean, should be given hypodermically in doses of from one-sixtieth to one-fortieth of a grain (0.001 to 0.0015 Gm.), repeated at intervals according to the exigencies of the case. Strychnine would also probably be found useful. The best preparation of Calabar bean is the alcoholic extract. (See *Extractum Physostigmatis*.) Its maximum commencing dose may be set down as one-eighth of a grain (0.008 Gm.), representing three grains of the crude drug (0.2 Gm.). The alkaloid *physostigmine* or *eserine*, either in solution or in the form of gelatin disks containing definite quantities (from 1-5000th to 1-1000th of a grain), which are put in the eye, has entirely replaced the alcoholic extract as a local myotic.

Dose, of Calabar bean, three grains (0.2 Gm.).

PHYSOSTIGMINÆ SALICYLAS. U. S.

PHYSOSTIGMINE SALICYLATE [Eserine Salicylate]

(phÿ-sò-stig-mī'næ sāl-i-cy'läs)

$C_{15}H_{21}N_3O_5 \cdot C_7H_6O_3 = 410.21$

"The salicylate [$C_6H_4(OH)COOH \cdot C_{15}H_{21}N_3O_2$] of an alkaloid obtained from *Physostigma*. It should be kept in small, dark amber-colored, well-stoppered vials." U. S.

Salicylate d'Eserine, *Fr. Cod.*; *Physostigminum salicylicum*, *P. G.*; *Physostigminsalicylat*, *Eserinsalicylat*, *G.*

Preparation.—This salt was introduced into the Pharmacopœia of 1880 and retained in that of 1890 and the 8th Revision. It is preferred to the sulphate of the alkaloid (see page 940) on account of its greater stability. Its advantage is that it is not deliquescent. Birkenwald (*Ph. Z. R.*, 1891, 657) gives the following process: 100 parts of physostigmine sulphate are dissolved in a suitable quantity of water, and an excess of a solution of sodium bicarbonate added and agitated with several portions of absolute ether; the ethereal solutions are filtered into a beaker containing 35.5 parts of salicylic acid dissolved in ether, thoroughly mixed, and the physostigmine salicylate collected upon a filter, washed with absolute ether and dried, protected from sunlight and air. Any excess of salicylic acid that may have been present is removed by the washing with ether. The success of this method depends upon rapid manipulation and preventing exposure to sunlight, otherwise the salt obtained will be of a red color due to the decomposition of physostigmine and formation of *rubeserine*; washing the crystals with alcohol will remove any red color, but with loss of physostigmine salicylate.

Properties.—It is officially described as "colorless, or faintly yellowish, shining, acicular, or short columnar crystals; odorless, and having a slightly bitter taste. It should be tasted with great caution. It acquires a reddish tint when long exposed to light and air. Soluble in 72.5

parts of water, 12.7 parts of alcohol, 175 parts of ether, and in 8.6 parts of chloroform at 25° C. (77° F.); soluble in 15 parts of water at 80° C. (176° F.), and in 4 parts of alcohol at 60° C. (140° F.). When heated, Physostigmine Salicylate begins to soften and turn slightly yellow at 160° C. (320° F.), and melts at 178.9° C. (354° F.). It leaves no residue on incineration. Its aqueous solution shows an acid reaction to litmus paper, and upon standing twenty-four hours the solution acquires a pink color. Ferric chloride T.S., produces in an aqueous solution of Physostigmine Salicylate a deep violet color; a solution of chlorinated lime added to the aqueous solution produces a red color. On evaporating an aqueous solution of the salt to dryness with a few drops of ammonia water, a blue residue is produced, which is soluble in alcohol, and when so dissolved, yields a red fluorescent solution upon the addition of acetic acid in excess. An aqueous solution of the salt is colored cherry-red by the addition of potassium hydroxide T.S., changing to a darker red, and finally to green. Platinic chloride T.S. produces no precipitate in solutions of the salt (distinction from *physostigmine sulphate*). Sulphuric acid containing in each Cc. 1 drop of solution of formaldehyde gives with Physostigmine Salicylate a bright pink color; sulphuric acid with a few particles of cane sugar produces a yellow color, turning to brown, then to purple, and finally to greenish-black. If 0.005 Gm. of the salt be dissolved in nitric acid, a yellow solution results, which, on being heated, changes to an orange-color, then to blood-red, and on evaporation to dryness yields a green residue. When exposed to the fumes of nitric acid this residue becomes violet-blue, and when a drop of nitric acid is added to it, it forms a reddish-violet solution, which soon changes to blood-red, and finally, on standing, or on dilution, becomes greenish-yellow." *U. S.*

Uses.—This salt has the medicinal properties of its base. It has long been used as a subcutaneous laxative in colic of horses, but has been chiefly employed in human medicine as a myotic. Nevertheless, it is a valuable addition to laxatives when there is intestinal muscular atony; given hypodermically, it may be of great service in acute conditions of the alimentary canal with *atonic tympany*. For ordinary ophthalmic purposes a solution of a quarter of a grain of the salt of physostigmine to the ounce is of sufficient strength, but in *glaucoma* and other severe diseases of the eyes the strength of two grains to the fluid-ounce is sometimes necessary. When a long continued use of the drug is desired, one-sixteenth grain to the ounce is usually of sufficient strength. Physostigmine solution soon acquires a pinkish color, which deepens with age, but does not sensibly affect the action of the drug upon the eye.

Dose, 1-80th to 1-30th grain (0.0008 to 0.002 Gm.).

PHYSOSTIGMINÆ SULPHAS.

U. S., Br.

PHYSOSTIGMINE SULPHATE [*Eserine Sulphate*]

(phÿ-sq-stig-mī'næ sŭl'phās)

$(C_{15}H_{21}N_3O_2)_2 \cdot H_2SO_4 = 643.75$

"The sulphate $[SO_2(OH)_2 \cdot (C_{15}H_{21}N_3O_2)_2]$ of an alkaloid obtained from *Physostigma*. It should be kept in well-stoppered, dark amber-colored vials." *U. S.* "The sulphate, $(C_{15}H_{21}N_3O_2)_2 \cdot H_2SO_4 \cdot xH_2O$, of an alkaloid obtained from *Calabar Bean*." *Br.*

Sulfate d'Esérine, *Fr. Cod.*; Physostigminum sulfuricum, *P. G.*; Physostigminsulfat, *G.*; Sulfato de eserina, *Sp.*

This was a new official salt in 1890; it is preferable to the salicylate on account of its greater solubility, but on exposure to the air it soon assumes an extractive consistence which renders it difficult to dispense; the salicylate is free from this objection.

Preparation.—*Physostigmine* or *eserine sulphate* is obtained by M. A. Petit in the following manner: A hydro-alcoholic extract of the bean is dissolved in four parts of distilled water, and the solution filtered. To the solution is added one gramme of potassium bicarbonate for every 20 grammes of extract, and the mixture is shaken with ether in excess. The ether, which takes up nearly all the alkaloid, is, after a few minutes' repose, separated. A little distilled water is then added, and afterwards sulphuric acid drop by drop, the liquid being shaken after each drop, and tested with litmus paper until exactly neutral. After standing, the aqueous solution is separated from the ether, which now contains none of the alkaloid. This ether is then employed as before, and the operation repeated three or four times, so as completely to exhaust the original solution, and the liquid obtained each time is added to the last aqueous solution. This contains the physostigmine sulphate nearly pure. To purify this, it should be passed through the same process as the original solution of the extract. The resulting solution may be evaporated to crystallization if desired; but usually the evaporation is carried only so far as to get rid of all the ether present. If enough water be added to the solution to make as many grammes as there were drops of sulphuric acid (H_2SO_4) employed, each gramme will represent one centigramme of the alkaloid.

Petit and Polonovski conducted experiments with the view of discovering salts of eserine which would be stable and non-hygroscopic; they made *eserine benzoate*, *eserine meta-cresotate*, *eserine citrate*, and *eserine tartrate*. Processes will be found in *J. P. C.*, 1894, 55.

Properties.—It is officially described as "a white or yellowish-white, micro-crystalline powder, odorless, and having a bitter taste. It should be tasted with great caution. It is

very deliquescent, and gradually turns reddish by exposure to air and light. Very soluble in water, alcohol, and chloroform; soluble in 1200 parts of ether at 25° C. (77° F.). When heated to 130° C. (266° F.), the salt becomes soft, and melts at about 140° C. (284° F.). Upon ignition, it is slowly consumed, leaving no residue. Its aqueous solution shows an acid reaction to blue litmus paper. Barium chloride T.S. produces in an aqueous solution of the salt a white precipitate, which is insoluble in hydrochloric acid. An aqueous solution of Physostigmine Sulphate yields, with alkalies, a white precipitate, which quickly turns pink, and dissolves in an excess of the alkali, forming a pink or red solution, which soon fades to yellowish-green. Gold chloride T.S. gives with aqueous solutions of the salt a purple color. Platinic chloride T.S. produces in aqueous solutions of the salt a yellowish-white precipitate (distinction from *physostigmine salicylate*). Sulphuric acid with Physostigmine Sulphate yields only a faint yellow color. Sulphuric acid containing a crystal of potassium iodate, on being added to a crystal of the salt, gives a light purple color, immediately changing to yellowish-red. If 0.005 Gm. of the salt be dissolved in nitric acid, a yellow solution results, which, on being heated, changes to an orange-color, then to blood-red, and, on evaporation to dryness, yields a green residue. When exposed to the fumes of nitric acid, this residue becomes violet-blue, and when a drop of nitric acid is added to it, it forms a reddish-violet solution, which soon changes to blood-red, and finally, on standing, or on dilution, becomes greenish-yellow." *U. S.* "When shaken with dilute solution of potassium hydroxide it becomes red; and when mixed with solution of ammonia and evaporated to dryness on a water-bath, it leaves a bluish residue, the solution of which in very dilute acids is dichroic, being red by reflected and blue by transmitted light. A minute fragment dissolved in a few drops of fuming nitric acid yields a yellow liquid, which on evaporation on a water-bath darkens in color, the residue when completely dried being of a green color. A dilute aqueous solution applied to the eye causes contraction of the pupil. It leaves no ash when burned with free access of air." *Br.*

The medicinal properties, uses, and dose are the same as those of *Physostigminæ Salicylas*.

Off. Prep.—*Lamellæ Physostigminæ, Br.*

PHYTOLACCA. *U. S.*

PHYTOLACCA [*Poke Root, Phytolaccæ Radix, Pharm. 1890*]

(phÿ-to-lăc'că)

"The dried root of *Phytolacca decandra* Linné (Fam. *Phytolaccaceæ*), collected in autumn." *U. S.*

Phytolacca Root; *Racine de Phytolaque, Fr.*; *Kermesbeerenwurz, G.*

Phytolacca decandra, L., *Sp. Pl.* (1762) 631; Willd., *Sp. Pl.* ii. 822; Bigelow, *Am. Med. Bot.*, i. 39; Barton, *Med. Bot.*, ii. 213—This is an indigenous plant, with large perennial root, often five or six inches in diameter, divided into two or three principal branches, soft, fleshy, fibrous, whitish within, and covered with a brownish cork. The stems, which are annual, frequently grow to the height of six or eight feet and divide into numerous spreading branches. They are round, very smooth, green when young, but purple after the berries have ripened. The leaves are scattered, ovate-oblong, entire, pointed, smooth, ribbed beneath, and on short footstalks. The flowers are numerous, small, and in long racemes, which are sometimes erect, sometimes drooping. The corolla consists of five ovate, concave, whitish petals, folding inward. There are ten stamens and the same number of pistils. The raceme of flowers becomes a cluster of dark purple, almost black shining berries flattened above and below, and divided into ten cells, each containing one seed.

The poke is abundant in all parts of the United States, flourishing along fences, by the borders of woods, and especially in newly cleared and uncultivated fields. The muck thrown up from the ditches of swamps is peculiarly favorable to it, and a bed of muck may almost always be recognized by the luxuriant growth of poke with which it covers itself. It also grows spontaneously in Northern Africa and Southern Europe, where, however, it is supposed to have been introduced from America. Its flowers begin to appear in July, and the fruit ripens in autumn. The magnitude of the poke weed, its large rich leaves, and its beautiful clusters of purple berries, often mingled upon the same branch with the green unripe fruit and the flowers still in bloom, render it one of the most striking of our native plants. The young shoots are much used as food early in the spring, boiled in the manner of spinach. The ashes of the stems and leaves contain a very large proportion of potassium salts, yielding, according to Braconnot, not less than 4.2 per cent. of the pure caustic alkali. In the plant the potassium hydroxide is combined with an acid closely resembling malic acid, though differing from it in some respects. The leaves, berries, and root are used, but only the latter is now mentioned in the Pharmacopœia. The root is most active. It should be dug up late in November, cut into thin transverse slices, and dried with a moderate heat. As its virtues are diminished by keeping, a new supply should be procured every year. The berries should be collected when perfectly ripe, and the leaves about the middle of summer, when the footstalks begin to redden.

The berries, formerly official (*Phytolaccæ Fructus, U. S. 1890, Phytolaccæ Baccæ, U. S. 1880, Poke berry*), contain a succulent pulp, and yield upon pressure a large quantity of

fine purplish red juice. They have a sweetish, nauseous, slightly acrid taste, with little odor. They were officially described as "a depressed-globular, dark purple, compound berry, about 8 Mm. in diameter, composed of ten carpels, each containing one lenticular, black seed; juice purplish-red; inodorous; taste sweet, slightly acid." *U. S.* 1890. The coloring principle is evanescent, and cannot be applied to useful purposes in dyeing, from the difficulty of fixing it. Alkalies render it yellow, but the original color is restored by acids. The juice contains saccharine matter, and, after fermenting, yields alcohol by distillation.

The dried root is branched, of a light yellowish-brown color externally, very much wrinkled, and, when in transverse slices, exhibits on the cut surface numerous concentric rings, formed by the projecting ends of fibres, between which the intervening matter has shrunk in drying. The structure internally in the older roots is firm and almost ligneous; the color yellowish white, alternating with darker circular layers. The fracture is fibrous, the wood-bundles in several distinct, concentric circles. There is no odor. The taste is slightly sweetish, and at first mild, but followed by a sense of acrimony.

Properties.—By the *U. S. Pharm.*, it is described as "cylindrical, somewhat tapering, sparingly branched, 3 to 7 Cm. thick, mostly in transverse or longitudinal slices, externally yellowish-brown, finely longitudinally or spirally wrinkled and thickly annulate with lighter colored, low ridges; fracture fibrous, characterized by alternating layers of fibrovascular tissue and parenchyma, the layers of the latter being much retracted; odor slight; taste sweetish, afterwards highly acrid." *U. S.* The active matter is imparted to boiling water and alcohol. From the analysis of Edward Donnelly, the root appears to contain tannic acid, starch, gum, sugar, resin, fixed oil, and lignin, besides various inorganic substances. (*A. J. P.*, xv. 169.) Claussen (*Pharm.*, 1879, p. 466) prepared from the seeds of *Phytolacca decandra*, by extraction with alcohol, evaporation to dryness, and taking up with chloroform or ether, after washing the residue with petroleum benzin, a neutral principle in silky lustrous crystals, insoluble in water, soluble in alcohol, ether, and chloroform, which he named *phytolaccin*. A. Tereil (*C. R. A. S.*, 91, 856) obtained from the berries an acid (*phytolaccic acid*) as an uncrySTALLIZABLE yellowish-brown mass of gummy consistency. It was soluble in water and alcohol, slightly soluble in ether, of acid reaction, and gelatinizing with hydrochloric and sulphuric acids. W. F. Wagner (*A. J. P.*, 1887, p. 69) found tannin in the berries, but not in the root. W. A. Partee (*A. J. P.*, 1888, p. 123) made a proximate examination of poke root and found crystals deposited from a solution of an alcoholic extract in absolute alcohol; he also discovered traces of tannin, glucose, and indications which pointed to the presence of a gluco-

sidal principle. Frankforter and Ramaley (*A. J. P.*, 1897, 281) have again analyzed the root with care. They find nearly 10 per cent. of a non-reducing sugar, free acid, identified as formic acid, but no certain proof of either alkaloid or glucoside. The very bitter resin amounted to 1 per cent.; *phytolaccine*, an alkaloid, has been said to exist in minute quantity in the root.

Uses.—*Phytolacca* is emetic, purgative, and somewhat narcotic. As an emetic it is very slow in its operation, frequently not beginning to cause vomiting in less than one or two hours after it has been taken, and then continuing to act for a long time upon both the stomach and the bowels. The vomiting produced by it is said not to be attended with much pain or spasm, but narcotic effects have been observed by some physicians, such as drowsiness, vertigo, and dimness of vision. In overdoses it produces excessive vomiting and purging, attended with great prostration of strength, and sometimes with convulsions. A woman (*Stethoscope* for March, 1852, ii. 134) ate a double handful of the berries. Free purgation followed upon the first day, after which coma set in, with great prostration, though death did not occur until after the sixth day. A child, six years old, after having swallowed two or three fluidrachms of a tincture of the root, was seized in less than an hour with tonic spasm of the muscles, the extremities being stiff, the hands clenched, the feet extended and toes flexed, and the trunk in a condition of opisthotonos. (*A. M. S. J.*, July, 1866.) According to Roberts Bartholow, *phytolacca* causes in the lower animals convulsions and death from paralysis of respiration. It is not fit for use as an emetic, but has been employed as an alternative with asserted good results in the treatment of *chronic rheumatism*, *granular conjunctivitis*, and even of *cancer*. Locally it has been used in the form of ointment (a drachm to the ounce) in the treatment of *psora*, *tinea capitis*, *sycosis*, and *favus*. It occasions at first a sense of heat and smarting in the parts to which it is applied. A saturated tincture of the berries may be given in rheumatic cases, in the dose of a fluidrachm (3.75 Ce.), three times a day. Alcohol, diluted alcohol, and water, extract the virtues of poke root.

Dose, emetic, ten to thirty grains (0.65 to 2.0 Gm.); alternative, one to five grains (0.065 to 0.32 Gm.).

Off. Prep.—Fluidextractum *Phytolacæ*, *U. S.*

PICROTOXINUM. Br.

PICROTOXIN

(pic-ro-tōx-in-um)

$C_{30}H_{34}O_{13}$ = 597.74

"A neutral principle obtained from the fruits of *Anamirta paniculata*, *Colebr.*" *Br.*

Picrotoxin was not retained in the U. S. P. 8th Revision. This substance is obtained from *Cocculus indicus* (*Anamirta paniculata*), for an account of which see PART II. The formula $C_{15}H_{18}O_6 + H_2O$ which is often given for picrotoxin belongs, according to Paterno and Ogli-aloro (*Gazz. Chim.*, ii. 41), to *picrotoxinin*, which with *picrotin*, $C_{15}H_{18}O_7$, is a decomposition product of the original picrotoxin, $C_{30}H_{34}O_{13}$.

Properties.—Picrotoxin was thus described in the U. S. 1890: "Colorless, flexible, shining, prismatic crystals, or a micro-crystalline powder, odorless, and having a very bitter taste; permanent in the air. Soluble, at $15^{\circ} C.$ ($59^{\circ} F.$), in 240 parts of water, and in 9 parts of alcohol; in 25 parts of boiling water, and in 3 parts of boiling alcohol; also soluble in solutions of the alkalies, and in acids. Very slightly soluble in ether or chloroform. Picrotoxin is neutral to litmus paper. When heated to $200^{\circ} C.$ ($392^{\circ} F.$), picrotoxin melts, forming a yellow liquid, and upon ignition it is consumed, leaving no residue. Concentrated sulphuric acid dissolves Picrotoxin with a golden-yellow color, very gradually changing to reddish-brown, and showing a brown fluorescence. On mixing about 0.2 Gm. of powdered sodium nitrate with 3 or 4 drops of sulphuric acid, in a small, flat-bottomed capsule, sprinkling a minute quantity of Picrotoxin over it, and then adding, from a pipette, concentrated solution (1 in 4) of sodium hydrate, drop by drop, until it is in excess, the particles of Picrotoxin will acquire a brick-red to deep red color which fades after some hours. On diluting 2 Cc. of alkaline cupric tartrate volumetric solution with 10 Cc. of water, and adding a small portion of Picrotoxin, red cuprous oxide will be separated within half an hour at ordinary temperatures, and much more rapidly upon the application of heat. The aqueous solution of Picrotoxin should remain unaffected by mercuric or platinic chloride test-solution, tannic acid test-solution, mercuric potassium iodide test-solution, or other reagents for alkaloids (absence of *alkaloids*)." U. S. 1890. The British Pharmacopœia describes it as follows: "It melts at $378^{\circ} F.$ ($192.2^{\circ} C.$). It is soluble in 330 parts of cold or 35 of boiling water, and in 13 of cold or 3 of boiling alcohol (90 per cent.). It is soluble in 10 parts of solution of potassium hydroxide, and the resulting liquid, on boiling, immediately reduces *Fehling's solution*. Heated on platinum foil, the crystals melt, forming a yellowish liquid, which on further heating, becomes charred, and is at length completely dissipated. It dissolves in sulphuric acid with a saffron-yellow color. Its aqueous solution is not precipitated by test-solution of mercuric chloride, solution of platinic chloride, or solution of tannic acid (distinction from alkaloids)." Br. E. Schmidt and Löwenhardt, who made a study of picrotoxin (*Ber. d. Chem. Ges.*, xiv. 812), found with it several principles. They identified

the easily soluble body *picrotoxinin*, $C_{15}H_{18}O_6$, fusing point from 200° to $201^{\circ} C.$, and the difficultly soluble anhydrous *picrotin*, $C_{15}H_{18}O_7$, fusing point from 240° to $245^{\circ} C.$ Picrotoxinin shows a brick-red color, when tested with the Langley reaction,¹ while picrotin is indifferent in this case. See a paper by Meyer and Bruger, *Ap. Ztg.*, 1899, 67. To procure picrotoxin, the aqueous extract of the seeds is triturated with pure magnesia, and then treated with hot alcohol, which dissolves the picrotoxin, and yields it upon evaporation. In this state, however, it is impure. To obtain it colorless it must be again dissolved in alcohol, and treated with animal charcoal. After filtration and due evaporation, it is deposited in the crystalline form. Accompanying the picrotoxin in the seeds is *anamirtin*, $C_{15}H_{24}O_{10}$. Possibly identical with this is the *cocculin* of Löwenhardt, to which, however, the formula $C_{15}H_{24}O_{10}$ is given by its discoverer. It does not give any color with the Langley reaction. Besides picrotoxin, *Cocculus indicus* contains a large proportion of fixed oil, and other substances of less interest. In the shell Pelletier and Couërbe discovered two distinct principles,—one alkaline and named *menispermine*, $C_{15}H_{22}N_2O_2$, the other identical with it in composition, but distinguishable by its want of alkalinity, its volatility, and its solubility and crystalline form, and denominated *paramenispermine*. They found also in the shell a new acid, which they called *hypopicrotoxic*. The picrotoxin of Boullay they believed to possess acid properties, and proposed for it the name of *picrotoxic acid*. (*J. P. C.*, xx. 122.)

¹ In Europe, picrotoxin is said to be added to malt liquors in order to give them bitterness and intoxicating properties,—although the practice is forbidden by law in England, under heavy penalties. Gunkel proposes the following mode of detecting and separating picrotoxin from liquids containing it, founded on the facts that it is soluble in dilute acids though not combining with them, and that ether extracts it from its acid solutions, but not from those in water or alcohol, even in the presence of potassium hydroxide. The substance suspected to contain it, having been brought to the consistence of paste, is to be digested with alcohol and a little tartaric acid, the liquid separated, the alcohol evaporated, the residue diluted with a little water and then treated with ether, and, finally, the ethereal solution submitted to evaporation in a watch glass. Picrotoxin, if present, is deposited, recognizable by its feathery crystallization, its bitter taste, and the property of reducing the tartrate of copper and potassium. If strychnine, which perhaps resembles it most closely in its effects, is present, it will be left behind in the acidulated solution. (*J. P. C.*, 1858, p. 78; from *A. Pharm.*, xlv. 14.) In the instance of adulterated malt liquor, in consequence of the resin of hops it contains, it might be expedient first to evaporate the liquor to dryness, and prepare an aqueous extract of the residue, and then to proceed as stated. J. W. Langley proposes, as a means of detection, the oxidation of picrotoxin. When to a little of this substance, mixed with potassium nitrate in a watch glass, a drop of sulphuric acid is added, no observable reaction takes place; but, if a very strong solution of potassium or sodium hydroxide be now added, a bright reddish-yellow color will be produced, which will be highly characteristic. A very minute quantity may thus be detected. Langley, however, thinks it probable that this phenomenon is owing to a minute quantity of some nitrogenous principle, for if picrotoxin be purified by combining it in solution with potassium hydroxide, and then precipitating it with an acid, it does not answer the test. (*Am. J. Sci.*, 1862.)

Uses.—Picrotoxin is a violent poison to all classes of animals, producing when in sufficient dose violent convulsive attacks, both epileptic and tetanic, with periodic arrest of respiration, slowing of heart beat, and finally death. An almost characteristic phenomenon is the interchange between tonic and clonic convulsions, with a peculiar, almost purposive movement in the clonic attacks; the motions of swimming, of walking, of rotation, of eating, etc., are usually some or all of them present. Vomiting sometimes occurs; the pupils are usually primarily contracted, secondarily dilated, and stupor deepens finally into coma. The convulsive movements are largely due to intense excitement of the motor cells in the medulla and spinal cord. The respiratory centres as well as the vasomotor centres share in this action, the condition of excitement being probably followed in fatal cases by one of secondary depression and exhaustion. During the period of convulsion the reflex activity is often abated, especially directly after a convulsive attack. This, taken with the fact that section of the cord high up at such a period brings on return of reflex activity, has led to the conclusion that the drug powerfully stimulates Setschenow's centre and thereby arrests reflex movement. The experiments of Gottlieb, however (*A. E. P. P.*, Bd. xxx., 1892), seem to show that small doses increase reflex activity by stimulating the motor cells, and he believes that the apparent loss of reflex activity after large doses is the result of exhaustion due to the motor discharges, the return of the reflex activity after section of the cord being due to the arrest by such section of the convulsive attacks, and consequent prevention of exhaustion. This does not, however, seem probable, and, as asserted by Kóssa (*S. J.*, Sept. 1894), the motor tract of the medulla and spinal cord is probably in the end paralyzed by the poison. Small doses of picrotoxin have a pronounced influence in increasing the blood pressure, which increase seems from the experiments of Gottlieb to be chiefly due to excitement of the vasomotor centres. The slowing of the heart produced by picrotoxin is largely owing to the extreme irritation of the inhibitory centres, but it would seem also that the poison has an influence directly upon the heart itself, since Falek has noted immediate slowing and quick arrest of the isolated frog's heart when picrotoxin solution is brought in contact with it. The final arrest of the heart is in diastole. According to Kóssa, the motor nerves and the voluntary muscle are not affected by the poison, which produces, however, violent peristalsis in the uterus and the intestinal tract.

In man, picrotoxin acts as it does in the lower animals, and a number of cases of serious or even fatal poisoning have been produced by it or by substances containing it. Planat commends it highly in *epilepsy*, *hystero-epilepsy*, *chorea*, and similar nervous disorders, and Dujardin-Beaumez states that he has found it

very useful in epilepsy in ascending doses of from one-fourth to three milligrammes. It has also been used with alleged excellent results in *night sweats*, especially by Semmola. There seems to be little reason for believing it to be of value in practical medicine, but the experiments of M. Koppen (*A. E. P. P.*, xxix., 1892) indicate that it is an active physiological antidote to poisons of the chloral group. In Kóssa's experiments (*Ungar. Arch. f. Med.*, i. 1892) it was found to increase the toxic action of morphine.

Dose, from 1-100 to 1-30 of a grain (0.0006 to 0.002 Gm.).

PILOCARPINÆ HYDROCHLORIDUM.

U. S.

PILOCARPINE HYDROCHLORIDE [Pilocarpine Hydrochlorate, Pilocarpinæ Hydrochloras, Pharm. 1890]

(pī-lō-cār-pī'næ hŷ-drō-ghlōr'ī-dŭm)

$C_{11}H_{16}N_2O_2 \cdot HCl = 242.81$

"The hydrochloride [$HCl \cdot C_{11}H_{16}N_2O_2$] of an alkaloid obtained from *Pilocarpus*. It should be kept in well-stoppered, amber-colored vials." *U. S.*

This alkaloidal salt is usually obtained by the process given under *Pilocarpus* for the alkaloid (see page 948). Although the nitrate is more frequently found in commerce at present, the hydrochloride has been preferred, principally because of its more ready solubility in water. Schuchardt states (*N. R.*, May, 1881) that 100 parts of boiling water dissolve 66 parts of pilocarpine hydrochloride, and water at 15° C. (59° F.) dissolves nearly the same amount; of alcohol of sp. gr. 0.820 it requires 7 parts for solution at 15° C. (59° F.), while the same alcohol, boiling, easily dissolves 2½ parts of the salt. According to the same authority, pilocarpine nitrate is soluble at 15° C. (59° F.) in 8 parts of water. At 100° C. (212° F.) it has the same solubility as the hydrochloride. It requires 130 parts of alcohol of sp. gr. 0.820 at 15° C. (59° F.), and 40 parts of boiling alcohol, to dissolve it. These figures do not agree with the official solubilities.

Properties.—Pilocarpine hydrochloride is officially described as in "colorless, or white, transparent crystals, odorless, and having a faintly bitter taste; deliquescent on exposure to the air. It contains no water of crystallization. Soluble in 0.3 part of water, 2.3 parts of alcohol, and in 540 parts of chloroform at 25° C. (77° F.); soluble in 1.1 parts of alcohol at 60° C. (140° F.); insoluble in ether. After drying for several hours at 100° C. (212° F.), the salt melts at 195.9° C. (384.5° F.), and upon ignition it is entirely consumed. Its aqueous solution is neutral, or has a faintly acid reaction upon blue litmus paper. Sulphuric acid dissolves Pilocarpine Hydrochloride.

ride, with elimination of hydrochloric acid gas and the formation of a colorless liquid; upon adding to the solution a small fragment of potassium dichromate on a white porcelain surface, a bright, grass-green color is produced. If 0.01 to 0.02 Gm. of the salt be dissolved in 2 Cc. of water in a test-tube, 2 Cc. of a slightly acid solution of hydrogen dioxide added, and a small layer of benzene be carefully poured upon the liquid, then if 3 or 4 drops of a solution of potassium dichromate (1 in 300) be added and the mixture be gently shaken, the benzene layer will acquire a violet color, while the aqueous layer will remain yellow (distinction from *other alkaloids*). If more than 0.02 Gm. be used, the benzene turns blue, and the reaction is no longer characteristic). On rubbing together equal parts of Pilocarpine Hydrochloride and mercurous chloride, a black color is produced. Silver nitrate T.S. produces, in an aqueous solution of the salt, a white precipitate insoluble in nitric acid." *U. S.*

Uses.—Pilocarpine hydrochloride is superior to pilocarpus in the certainty of its diaphoretic action, and in being less disagreeable, and probably less apt to nauseate. Weber, Bardenheuer, and Auschmann agree that 0.3 of a grain of it is equal to seventy-five grains of the best leaves, but this is probably an overestimate of its powers. The hydrochloride may be used hypodermically in aqueous solution; the commencing dose is an eighth of a grain (0.008 Gm.), although much larger doses are sometimes necessary. A solution of the salt is sometimes used by oculists as a myotic. Pilocarpine is often used with advantage for the stimulation of other secretions than those of the skin. Cheron affirms that it is an active galactagogue. When given in doses of from one-twentieth to one-fifteenth of a grain (0.003 to 0.004 Gm.), at intervals of two or three hours, it frequently acts as a powerful hydragogue diuretic. According to Watowski and others, it is of value in the treatment of *catarrhal jaundice*. In the form of gelatin disks (each containing from one-twelfth to one-fifteenth of a grain), allowed to dissolve slowly in the mouth, it has been used with alleged satisfaction against the exceedingly dry mouth of *phthisis* and other chronic diseases.

Dose, one-eighth to one-fourth of a grain (0.008 to 0.016 Gm.).

PILOCARPINÆ NITRÆS. U. S., Br.

PILOCARPINE NITRATE

(pī-lō-cār-pī'nē nī'træs)

$C_{11}H_{16}N_2O_2.HNO_3 = 269.20$

"The nitrate [$NO_3OH.C_{11}H_{16}N_2O_2$] of an alkaloid obtained from *Pilocarpus*. It should be kept in well-stoppered, amber-colored vials." *U. S.* "The nitrate of an alkaloid, $C_{11}H_{16}N_2O_2.HNO_3$, obtained from *Jaborandi Leaves*." *Br.*

(60)

Preparation.—This salt may be made by adding pure pilocarpine to diluted nitric acid, carefully evaporating the solution, and purifying the crystals by solution in alcohol and recrystallizing.

Properties.—This salt was recognized in the U. S. P. for the first time in the 8th Rev. and it is there described as follows: "Colorless, or white, shining crystals, odorless, and having a faintly bitter taste; permanent in the air. It contains no water of crystallization. Soluble in 4 parts of water and in 60 parts of alcohol, at 25° C. (77° F.); soluble in 16 parts of alcohol at 60° C. (140° F.); insoluble in ether and chloroform. It melts at 170.9° C. (339.7° F.). Upon ignition, it is quickly consumed, leaving no residue. The aqueous solution (1 in 100) shows an acid reaction to blue litmus paper. Sulphuric acid dissolves Pilocarpine Nitrate, forming a colorless solution, and on adding a fragment of potassium dichromate, a bright grass-green color is produced. On rubbing together equal parts of the salt and mercurous chloride, no black color is produced (distinction from *pilocarpine hydrochloride*). If 0.01 to 0.02 Gm. of the salt be dissolved in 2 Cc. of water in a test-tube, 2 Cc. of a slightly acid solution of hydrogen dioxide added, and a small layer of benzene be carefully poured upon the liquid, then if three or four drops of a solution of potassium dichromate (1 in 300) be added and the mixture be gently shaken, the benzene layer will acquire a violet color, while the aqueous layer will remain yellow (distinction from *other alkaloids*). If more than 0.02 Gm. be used, the benzene turns blue and the reaction is no longer characteristic). If to an aqueous solution of the salt, mixed with an equal volume of ferrous sulphate T.S., sulphuric acid be carefully added without shaking, a brown ring will appear at the juncture of the two layers." *U. S.* The Br. Pharm. also recognizes the *nitrate*, which it describes as "a white crystalline powder; soluble in 8 or 9 parts of cold water; slightly soluble in cold, freely soluble in hot alcohol (90 per cent.). Strong sulphuric acid forms with it a yellowish solution which, on the addition of *potassium bichromate*, gradually acquires an emerald-green color. A dilute aqueous solution applied to the eye causes contraction of the pupil. It leaves no ash when burned with free access of air (absence of mineral impurity)." *Br.* The medicinal properties and dose are the same as those of *Pilocarpinæ Hydrochloridum*.

PILOCARPUS. U. S. (Br.)

PILOCARPUS [*Jaborandi*]

(pī-lō-cār'pūs)

"The leaflets of *Pilocarpus Jaborandi* Holmes or of *Pilocarpus microphyllus* Stapf (Fam. *Rutaceæ*), yielding, when assayed by the process

given below, not less than 0.5 percent. of alkaloids." U. S. "The dried leaflets of *Pilocarpus Jaborandi*, Holmes." Br.

Jaborandi Folia, Br.; Jaborandi leaves; *Pilocarpi Foliola*; Jaborandi, Fr. Cod.; *Folia Jaborandi*, P. G.; Jaborandiblätter, G.; Jaborandi, It.; Jaborandi (Hoja de), Sp.

Pilocarpus was first introduced to the notice of the European profession by Coutinho (*J. P. C.*, 4e sér., xx. 51) under the name of *Jaborandi*, a name which has adhered to the drug, although the terms *Jaborandi*, *Iaborandi* and *Jamborandi* are used in South America to designate various pungent, sudorific plants, most of which belong to the genus *Piper*, but some of which have no botanical relation at all with the peppers. Although the leaves of the *Piper Jaborandi* have been sent into commerce as *jaborandi*, none of the true *jaborandies* of South America have any physiological relations with the official drug, which in South America is known as *Arruda do Mato* or as *Arruda brava* and rarely as *Jamguarandi* or *Jaurandi*.

The genus *Pilocarpus* consists of woody shrubs belonging to the Rutaceæ and inhabits tropical and subtropical America, including Cuba, Guadeloupe, Martinique, and probably other islands. For an elaborate botanical and histological study of the commercial species of *Pilocarpus* by A. Duval, see *B. Sc. Pharm.*, vii., Feb. 1903. The commercially important species of the genus are as follows:

P. Jaborandi, Holmes; *P. officinalis*, Poehl. This plant inhabits the northern and northeastern part of Brazil whence its leaves find their way through Sergipe, Allogoa, Sobral and Ceará, etc., to Liverpool and Hamburg, the chief centres of European commerce in the drug. Like those of *P. selloanus* its leaves are two or three jugate and are especially separated from those of the *P. pennatifolius* by the fact that all of the leaflets except the terminal one have their bases cordate, while the bases of all the leaflets of *P. pennatifolius* are attenuate.

P. pennatifolius, Lemaire; *P. simplex*, Baillon, inhabits the southern portion of Brazil and Paraguay, whence its leaves were formerly largely exported through Buenos Ayres and Rio Janiero; at present they seem to have almost disappeared from commerce.¹ The leaves are oval, elliptical, obtuse, attenuate at the summit, which is feebly emarginate, and also attenuate at their base but not petiolated. The species is recognized in the French Codex.

P. selloanus, Engler, formerly official in the U. S. P., appears to be a variety of *P. pennatifolius*, Lemaire, from which it differs almost solely in the length of its flower stalk, which is six times as long as the flower bud, while that of *P. pennatifolius* is but three to four times

as long as the bud. *P. selloanus* seems to be the more southern plant of the two, and is especially abundant in Paraguay.

P. trachylophus, Holmes.—The leaves of this species are smaller than those of the *P. Jaborandi*, and are oblong, elliptical, obtuse and emarginate at the summit with cordate bases, symmetrically and shortly petiolate. The plant grows in Northeastern Brazil, especially in the provinces of Ceará and Maranhão and the leaves, although they contain so little of the alkaloid (about 0.2 per cent.) as to be of small value, have been sent into commerce in considerable quantities. Their color upon the surface is vivid green, below yellowish-green.

P. microphyllus, Stapf, grows in the northeastern part of Brazil whence the leaves, much mixed with the debris of the petioles, of the twigs and of the fruit, are sent to Liverpool and Hamburg. These leaves are alternate, imparipinnate with from one to five pairs of leaflets, or are often apparently simple owing to the failure of the lateral leaflets to develop. The leaflets are opposed, slightly pubescent, their petioles marked by a deep longitudinal furrow. They vary very much in form, the base usually being attenuate and feebly cordate or unequal.

P. spicatus, A. Saint-Hilaire; *P. parviflorus*, Martius et Nees, inhabits the southern and northern portions of Brazil and can be recognized at once by its having simple leaves which are from 3 to 11 Cm. long and from 1 to 4 Cm. broad, and are tender or coriaceous and more or less pubescent and dotted. *P. subcoriaceus*, Engler, is probably a variety of this species.

P. racemosus, Vahl, a native of Martinique, Cuba, Guadeloupe and probably other of the West Indian Islands, appeared first in commerce in 1903 as a new variety of *jaborandi* under the name of *Guadeloupe jaborandi*. The leaves are proportionately broader than those of *Pernambuco jaborandi*, more obovate in outline, of a purer green color, and are trifoliate or apparently simple. Considerable diversity of result has been obtained by chemists in the examination of the *Guadeloupe jaborandi*. Rocher (*A. J. P.*, 1900) obtained 1 per cent. of total alkaloids of which 0.6 per cent. was believed to be pilocarpine, the remainder jaborine. In the laboratory of Wright, Layman and Umney, only 0.34 per cent. of total alkaloids were reported as existing, while in an assay by A. J. Cownley (*P. J.*, vol. 72) 0.6 per cent. of total alkaloids was obtained, about 50 per cent. of which was believed to be isopilocarpine. The commercial cultivation of *jaborandi* may some day be successful as the *P. pennatifolius* has been found to grow freely in Sicily and produce a leaf containing a fair proportion of alkaloid. *Pilocarpus* is usually bought by assay. The variation in the percentage of alkaloid, according to the observations of A. Duval, depends not merely on the original contents of the drug but upon the fact that the alkaloid disappears when the pilo-

¹ In the original specimens of *jaborandi* seen by Coutinho, and also in other specimens received from the doctor's family by F. V. Greene, U. S. N., some of the leaves are hairy, although most of them are smooth, and it seems probable that the species does contribute somewhat to the *jaborandi* of commerce.

carpus is kept for some length of time in a moist atmosphere. It is probable that jaborandi is rarely purposely adulterated, but often there are to be found with *P. microphyllus* large quantities of the leguminous plant, *Tunatea decipiens* (Holmes), O. Kze. (*Swartzia decipiens*, Holmes). In general appearance the two leaves resemble one another, both being imparipinnate and having the leaflets about the same size and shape, but in *P. microphyllus* the leaflets are opposite and the petioles are only slightly pubescent, while in the *Tunatea* the leaflets are alternate and the petioles very pubescent. Then again, the absence of secreting hairs, the deep green of the upper and lighter green of the lower surface of the leguminous leaf serve easily to distinguish it from the true drug.

The following description of the drug is adapted from that of F. V. Greene, U.S.N., who had unquestionable specimens of the original jaborandi of Coutinho. The package contained several stems branched at an angle of about 20°, these branches being furnished with alternate leaves, which are imparipinnate, with from two to five opposite leaflets (Planchon has met with leaves having as many as seven or nine, and, more rarely, eleven leaflets) articulated to the rachis by short petiolules, thickened at the base. The leaflets, which are coriaceous in texture, vary considerably in size and outline. As a rule, they may be considered as oblong-lanceolate, and are entire, emarginate, with an unequal base. The midrib rises very little above the upper surface of the leaflet, but is very prominent and sharp on the lower. The veins, which are rather more prominent on the lower surface, leave the midrib at an angle of about 60°, pursue a parallel course across the leaflet, and finally turn up and anastomose within about a quarter of an inch of the margin. The leaflets are pellucidly punctate; the dots are the receptacles of secretion, are numerous and irregularly distributed over the whole surface, and are plainly visible when the leaflet is held up to the light.¹ The fruit consists of five carpels, of which not more than two or three are usually developed to maturity; when ripe, the carpels dehisce into two valves, and then remind one strongly of miniature cockle shells with the valves open exposing the animals. The black, shining, reniform seeds (one for each carpel) have a lancet-shaped hilum, a sharp ridge on the back near the apex, and a smooth, pale yellow endocarp surrounding it. There are in commerce at present two chief forms or varieties of jaborandi, one coming from Pernambuco and one from Para. The U. S. P. now recognizes these two varieties of pilocarpus, giving the following official descriptions of them. *Large Jaborandi*; *Pernambuco Jaborandi* from:

"Pilocarpus Jaborandi.—Very shortly and stoutly petioluled, the blades 6 to 12 Cm. long and 2 to 4 Cm. broad, oblong or oval, mostly unequal at the base, blunt and emarginate at the summit, the margin entire and narrowly revolute; yellowish-green, very smooth, shining, thick and coriaceous, the reticulate venation prominent on both sides, especially beneath; strongly pellucid-glandular; peculiarly aromatic when crushed; taste bitterish, slightly salty, aromatic, later somewhat pungent and sialagogue." U. S.

Para Jaborandi; *Maranhao* or *Maranhão Jaborandi*; *Small Jaborandi*:

"Pilocarpus microphyllus.—Leaflets 1.2 to 3.7 Cm. long, 0.8 to 1.6 Cm. broad; the lateral without petiolules, rhomboidally oval to obovate, acute at the base, blunt and unequally emarginate at the summit; the terminal on short, margined petiolules, almost equally oval to obovate, rather narrower than the lateral; all thickish and rigid, with entire margin, smooth and dull green, finely pellucid-glandular; midrib stout, the veins rather coarsely reticulate, lightly prominent; almost odorless; taste similar to that of *Pilocarpus Jaborandi*." U. S.

Paraguay jaborandi from *P. pennatifolius* and *P. selleanus* is an inferior variety of the drug, which reaches European commerce from Buenos Ayres and from Rio Janeiro, and is believed to be collected in Paraguay. The leaves are thinner than those of the Pernambuco jaborandi, and have only two or three, never four, pairs of leaflets. It is also noticeable in the Paraguay variety that the lateral veins are not prominent, that the base is so tapered that the widest portion is above the middle, and that the upper surface is grayish green.

In 1894 still another variety appeared in the London market under the name of *Ceará jaborandi*. It differs from those previously known by the dark brownish-green tint of the upper and the yellowish tint of the under surface of the leaflet, and by the under surface being covered with short hairs. It is yielded by *P. trachylophus*, first described by E. M. Holmes.

All of the older varieties of jaborandi are yielded by pinnate-leaved species of *Pilocarpus*, but in 1895 a papery, rather rigid, lanceolate, brittle leaf, of a dark, rather brownish green above, and a rather paler hue beneath, attached to a short twisted petiole, came into commerce under the name of *Aracati jaborandi*. (See table page 948.) It is the product of *P. spicatus*.

Properties.—An alkaloid was isolated in 1875 from jaborandi almost simultaneously by A. W. Gerrard and M. Hardy. To this the name of *pilocarpine* was given. Gerrard at the same time stated that there were at least two alkaloids in the leaves, and this view seemed to be confirmed when *jaborine* was discovered. He also obtained a volatile oil, tannic acid, a peculiar volatile acid, and potassium chloride. *Pilocarpine* may be prepared as follows. The

¹ According to Conroy, the leaflets yield 0.76 per cent., the leafstalks only 0.37 per cent. of alkaloid.

leaves are exhausted with 80 per cent. alcohol containing 8 grammes of hydrochloric acid in a liter, the tincture is distilled and evaporated to the consistence of a liquid extract, and this is mixed with a small quantity of water, and filtered. The filtrate is treated with a slight excess of ammonia, and then with a large quantity of chloroform. The chloroform solution is agitated with water, to which hydrochloric acid is added, drop by drop, in sufficient quantity to neutralize the alkaloid, the hydrochloride of which is obtained in long needles on evaporating the aqueous solution, while foreign principles remain dissolved in the chloroform. By dissolving the crystals in water, treating the solution with ammonia and chloroform, and evaporating the latter solution, pilocarpine is obtained as a soft viscous mass, which is only slightly soluble in water, but is freely soluble in alcohol, ether, and chloroform.

Kingzett assigned pilocarpine the formula $C_{10}H_{15}N_2O_4 + 4H_2O$. Harnack and Meyer, on the other hand, give it as $C_{11}H_{16}N_2O_2$. The latter was generally accepted, and is recognized by the U. S. Pharmacopœia. It is now definitely established as correct by the synthesis of pilocarpine afterwards effected by Hardy and Calmels. (*C. R. A. S.*, 105, pp. 68 to 71; also *A. J. P.*, 1887, p. 632.) By the action of

pine does not yield *jaborine* when heated at 100° C. for six hours, neither can this substance be obtained by the action of alcoholic iodides upon argento-pilocarpidine. If, however, carefully dried pilocarpine be heated rapidly to 175° C., kept at this temperature for about half an hour, and the product extracted with water, made alkaline with baryta and shaken with ether, the ether will contain *jaborine*, the aqueous solution will contain pilocarpidine and *jaboric acid*. *Jaborine* separates from alcohol or ether in a brown mass, which changes to a brittle resinous solid. Its composition is considered to be $C_{22}H_{32}N_4O_4$; it has exactly twice the molecular formula of pilocarpine. It is insoluble in water, but dissolves readily in ether, and is soluble in *jaboric acid*. *Jaboric acid*, $C_{10}H_{15}N_2O_5$, is separated from pilocarpidine by precipitating with excess of silver nitrate, which forms a curdy precipitate of the composition $C_{10}H_{15}N_2O_5$, $AgNO_3$. *Jaboric acid* resembles *jaborine* in appearance, but is very soluble in water, and is not removed from its aqueous solution by ether.¹ Pilocarpine combines with acids, and a number of the salts are to be had in commerce. The nitrate has probably been used most frequently, and it and the hydrochloride are now official. Gerrard tested the solu-

It may be of interest to mention here the relative percentage of alkaloids in the foregoing varieties, according to E. M. Holmes. (*P. J.*, lv.)

Jaborandi.	Per cent.
Pernambuco (<i>P. jaborandi</i>)	0.5 to 0.8 pilocarpine nitrate.
Paraguay (<i>P. pennatifolius</i> , etc.)	0.13 to 0.19 pilocarpine nitrate.
Maranhão (<i>P. microphyllus</i>)	0.16 to 0.19 pilocarpine nitrate.
Maranhão (<i>P. microphyllus</i>)	up to 0.8 alkaloidal nitrate.
Ceará (<i>P. trachylophus</i>)	0.02 new alkaloid (?)
Aracati (<i>P. spicatus</i> ?)	uncertain.

(See also *Proc. A. Ph. A.*, 1895, 266.)

hydrochloric acid or of barium hydroxide, pilocarpine, $C_{11}H_{16}N_2O_2$, is changed into *pilocarpidine*, $C_{10}H_{14}N_2O_2$, by the loss of a methyl group. Now Hardy and Calmels have converted β -pyridine- α -lactic acid, into *pilocarpidine*, the methyl iodide of which by oxidation is converted into pilocarpine. The synthetical pilocarpidine and pilocarpine yield gummy derivatives similar to those obtained by Harnack and Meyer from the natural products. The physiological action of synthetical pilocarpine is identical with that of the natural alkaloid. Knudsen, E. Merek, and Petit and Polonovski all dispute the conclusions of Hardy and Calmels, and state that they failed to get pilocarpine by the synthetic method of these investigators. (*Proc. A. Ph. A.*, 1897, 716.) Petit and Polonovski (*J. P. C.* (6), v. 481) obtained *pilocarpic* and *pilocarpidine acids* from pilocarpine and pilocarpidine. Harnack and Meyer first stated that *jaborine* is easily formed from pilocarpine, and may be produced by simply heating the latter alkaloid. They also showed that *pilocarpine* has physiological effects analogous to those of *nicotine*, while *jaborine* resembles *atropine* in its effects. Hardy and Calmels (*J. Chem. S.*, Sept. 1886, 815) state that pure, dry pilocar-

bilities of several of the salts as follows. The *nitrate* is soluble in water, sparingly in cold but freely in boiling alcohol; it is insoluble in chloroform, benzene, carbon disulphide, and ether. The *phosphate* is soluble in water, sparingly in cold, more freely in boiling alcohol, from which on cooling it crystallizes in lustrous tables; it is insoluble in ether, chloroform, benzene, and carbon disulphide. The *hydrochloride* is freely soluble in water, alcohol and chloroform; insoluble in ether, benzene, and carbon disulphide. The *acetate* is soluble in water, alcohol, chloroform, benzene, and ether; insoluble in carbon disulphide. The *hydrobromide* is soluble in water, alcohol, and chloroform; insoluble in ether and carbon disulphide. The U. S. P. (8th Rev.) introduced the following:

Assay.—"Pilocarpus, in No. 60 powder, ten grammes; Chloroform, Ammonia Water, Normal Sulphuric Acid V.S., Tenth-normal Sulphuric Acid V.S., Fiftieth-normal Potassium Hydroxide V.S., Cochineal T.S. or Iodocin T.S., each, a sufficient quantity. Moisten the Pilocarpus with 2 Cc. of ammonia water and 3 Cc. of chloroform, and at once pack it

¹ According to the researches of E. Harnack, *pilocarpidine* acts upon the animal organism in the same way as pilocarpine, but is somewhat less powerful.

firmly in a small cylindrical percolator, which has been provided with a pledget of cotton packed firmly in the neck. Percolate the powder slowly with chloroform containing about 2 percent. of ammonia water, until it is exhausted, about 100 Cc. of menstruum usually being sufficient. Pour into a separator the percolate, and shake it out with 15 Cc. of normal sulphuric acid V.S., transferring the acid aqueous layer to another separator, and repeating the shaking out of the chloroform solution with 2 Cc. of normal sulphuric acid V.S., mixed with 8 Cc. of distilled water. Add the acid layer to the second separator, and again repeat the shaking out with 10 Cc. of distilled water, and add the aqueous liquid to the second separator. Introduce into the second separator a small piece of red litmus paper, add enough ammonia water to render the liquid alkaline, and shake out the liquid with 20 Cc. of chloroform, drawing off the chloroformic solution into a beaker. Repeat the shaking out with two portions of 15 and 10 Cc. each of chloroform, and add the chloroformic solutions to the beaker. Evaporate the chloroform by means of a water-bath, and dissolve the alkaloidal residue in 7 Cc. of tenth-normal sulphuric acid V.S. Add 5 drops of cochineal T.S. or iodosin T.S., and titrate the excess of acid with fiftieth-normal potassium hydroxide V.S. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract the quotient from 7 (the 7 Cc. of tenth-normal sulphuric acid V.S. taken), and multiply the remainder by 0.02, and this product by 10; the result will be the percentage of alkaloids contained in the *Pilocarpus*. The figure 0.02 represents the weight in grammes of alkaloids (mainly pilocarpine) required to neutralize 1 Cc. of tenth-normal sulphuric acid V.S." *U. S.*

An essential oil of sp. gr. 0.875, and boiling between 180° and 290° C., has been obtained by Schimmel & Co., in Leipsic. (*Ber. d. Chem. Ges.*, April, 1888.) The portions going over above 260° C. solidified on cooling, and yielded a solid hydrocarbon, which fuses at 27° to 28° C. As it decolorizes notable amounts of bromine when in solution in petroleum benzin, it probably belongs to the olefine series. The yield of oil in *pilocarpus* is about 0.4 per cent. In a later report (Oct. 1893) they give as a probable constituent of the lower boiling portions of the oil, *dipentene*, $C_{10}H_{18}$. The total amount of essential oil varies, according to the freshness of the plant, from 0.2 to 1.1 per cent.

Uses.—When an infusion containing sixty to ninety grains of *Jaborandi* is given to an adult, in about ten minutes the face and neck become deeply flushed, and free perspiration and salivation commence. After a hypodermic injection of the alkaloid, the symptoms may set in in six minutes. The sweating begins on the face; both it and the salivation are excessively profuse, and last from three to five hours. There is frequently nausea, and sometimes

vomiting. The pulse is generally more or less quickened, as is also usually the respiration. After the sweating has ceased, the patient is left more or less exhausted. The nasal and lachrymal secretions are very generally increased under the action of the drug, and Gubler has noted diarrhœa. There is sometimes contraction of the pupils, and even disturbance of vision. These effects of the drug are in the adult fairly constant, but subjects have been occasionally found who were not susceptible to the action of the remedy, and, very curiously, in Ringer's experiments children were found to be very insusceptible, although doses of sixty grains were employed. Schwann and subsequent observers have noticed in the lower animals that very violent intestinal peristalsis is produced by the drug. The sweat produced by *Jaborandi* is often enormous in quantity (from nine to fifteen ounces by estimation). It is stated to be at first acid, then neutral, and finally often clearly alkaline, as is also the saliva. Not only the aqueous but also the solid portions are increased, and the elimination of urea is said especially to be affected. Usually, but not always, when the drug acts very moderately upon the skin the salivary glands are but slightly affected, and *vice versa*. The cause of the excessive secretion is a direct action upon either the gland cells or the peripheral nerve endings, most probably upon the former. In the first stages of sweating the bodily temperature sometimes rises, but it usually falls after the sweating.

When applied to the eye, pilocarpine produces great contraction of the pupil, tension of the accommodative apparatus, and an approximation of the nearest and farthest points of distinct vision, by a peripheral action. It is stated to produce less irritation than Calabar bean.

Jaborandi is the most reliable and powerful of the diaphoretics. In *dropsies* it has been widely employed, and certainly is a most efficient remedy. Great value has been ascribed to it in facilitating the removal of local aqueous effusions, such as occur in *pleurisy* and *pulmonic œdema*. In *uræmia* it is the most efficient remedy at our command. In the forming stage of subacute *rheumatism*, *coryza*, *influenza*, and similar conditions, pilocarpine may be very useful. In *acute* or *chronic Bright's disease* it is of great value, sufficing in the one case to bring about convalescence, and in the other greatly to prolong life and make it comfortable. The sweats may be repeated daily, bi-weekly, or weekly. Recently, the plan of giving very small doses at short intervals as a diuretic has been strongly commended.

Jaborandi is usually given in the form either of the fluidextract or of the alkaloid. The full diaphoretic dose of the fluidextract is from forty to sixty minims (2.5 to 3.75 Cc.), of a salt of pilocarpine one-sixth of a grain (0.01 Gm.). When excessive vomiting is produced by the drug, it is better to administer it

every ten minutes in fractional doses. After the second or third dose, unless contra-indicated, whisky and hot water should be given.

It has been proved by elaborate experimentation that in many of their actions upon the human system pilocarpine and atropine are directly antagonistic, and in poisoning by jaborandi or its alkaloid, atropine has the power to arrest the excessive secretion and save life. The value of pilocarpine in atropine poisoning is not quite so certain, but there is enough evidence to demand further trial of it. Purjesz of Buda-Pesth, reports (*Centralb. für Prakt. Augenhk.*, 1880) a case in which two and a half grains of atropine sulphate were said to have been taken, and relief, with final recovery, was secured by hypodermic injections of 0.4 grain of pilocarpine every ten minutes until 6.4 grains had been administered. For other similar but less striking cases, see *B. M. J.*, Jan. 1887; *L. L.*, July, 1890.

Dose, of jaborandi, from twenty to sixty grains (1.3 to 3.9 Gm.).

Off. Prep.—Fluidextractum Pilocarpi, *U. S.* (*Br.*); Tinctura Jaborandi, *Br.*

PILULÆ.

PILLS

(pil'ù-læ)

Pilules, Fr.; Pillen, G.; Pillole, It.; Pildoras, Sp.

These are globular masses of a size convenient for swallowing. They are well adapted for the administration of medicines which are unpleasant to the taste or smell, or insoluble in water, and which do not require to be given in large doses. Deliquescent substances should not be made into pills, and those which are efflorescent should be previously deprived of their water of crystallization. Care should be taken not to combine materials the mutual reaction of which may result in a change of form.

Some substances have a consistence which enables them to be made immediately into pills. Such are the softer extracts and certain gum-resins, and the addition of a little water to the former, and of a few drops of alcohol to the latter, will give them the requisite softness and plasticity, if previously wanting. Substances which are very soft, or in the liquid state, are formed into the pilular mass by incorporation with dry and inert powders, such as wheat flour, starch, and powdered gum arabic, or with crumb of bread. Powders must be mixed with soft, solid bodies, as extracts, confections, soap, etc., or with tenacious liquids, as syrup, molasses, honey, mucilage or glycerin and the last-mentioned substance has been especially recommended in connection with a little alcohol. Heavy metallic powders are most conveniently made into pills with the former; light vegetable powders with the latter. Mucilage is very often used, but pills made with it are apt when kept to be-

come hard and of difficult solubility in the liquids of the stomach, and if metallic substances are mixed with it the mass does not work well. A mixture of syrup and powdered gum arabic is not subject to the same inconveniences, and is an excellent material for the formation of pills. Honey evaporated to about half its bulk has been highly recommended. Confection of rose and glucose are among the best excipients, when the pills are to be kept long. For the same purpose of keeping the pills soft, the addition of a small portion of some fixed oil or deliquescent salt has been recommended, but glycerin is still better. Glycerin incorporated with one-twenty-fifth of its weight of powdered tragacanth is said to cause pills to remain soluble for almost any length of time. The official mucilage of tragacanth is an excellent excipient. Martindale prepares a mass by heating together with constant stirring to 115.5° C. (240° F.) five parts by weight of glycerin and one of flour, or, when a very firm mass is required, equal parts of flour and glycerin. (*P. J.*, 3d ser., i. 412.) It has been objected that pills made with glycerin could not be handsomely gilded or silvered, the lustre of the metal disappearing. This is true, however, only of very recent pills, or of those in which an excess of glycerin has been used. Many powders require only water. Such are all those which contain ingredients capable of forming an adhesive or viscid solution with the liquid. Care should always be taken that the substance added is not incompatible with the main constituents of the pill.

The materials should be accurately mixed together, and beaten in a mortar until formed into a perfectly uniform and plastic mass. This should be of such a consistence that the pills may preserve their form, without being so hard as to resist the solvent power of the gastric fluids. As pills frequently become very hard by time, it is often convenient to keep the mass in a state fit to be divided when wanted for use. This may be done by wrapping it in waxed paper, putting it in covered pots, and occasionally moistening it as it becomes dry, or, more effectually, by keeping it in glass or well glazed jars, accurately closed with rubber cloth. The mass is made into pills by rolling it with a spatula, or with a flat, smooth piece of hard wood, into a cylinder of precisely the same thickness throughout, and of a length corresponding to the number of pills required. It is then divided as equally as possible by the hand, or, more accurately, by a machine.¹ The pills receive a spherical form

¹ The common pill machine is too well known to require description. In *A. J. P.* (xxiv. 315) the reader will find the description of a rotary pill machine, calculated to prepare large numbers of pills in a short time, and in the same journal (xxvi. 118) that of another, which is considered an improvement on the first. (See also *A. J. P.*, Jan. 1869.) For illustrations and description of pill machines for making large quantities of pills at one time, see Remington's *Practice of Pharmacy*, 4th edition, p. 1219.

by being rolled between the fingers. Mialhe describes a little instrument for rolling pills, composed of two circular plates, one about 12 inches, the other 6, in diameter, the former having a ledge at the border one-third of an inch high, the latter with a similar ledge, varying, according to the size of the pills, from less than a line to nearly two lines, and with a strap on the back by which it can be fitted to the hand. This is to be moved in a rotary manner upon the larger plate, holding the divided portions of the pill mass. (*J. P. C.*, 3e sér., xvii. 218.) Similar pill rollers made of wood are now in use. In order to prevent the adhesion of pills to one another, or to the sides of the vessel in which they may be placed, it is customary to agitate them with some dry powder, which gives them an external coating, that serves also to conceal their taste. For this purpose magnesium carbonate, rice flour, or starch may be used. Magnesium carbonate is sometimes incompatible with one of the ingredients of the pills, and licorice root is then preferable, though it occasionally becomes mouldy with very damp pills. The powder of lycopodium, which has been long in use in Europe, is now considerably employed in this country, and is perhaps one of the best substances for the purpose. It is the custom in some sections of the United States, particularly on the Pacific coast, to give the pill a coating of gold or silver leaf. This is done by agitating the pills, prepared without dusting powder, and with their surface still damp, or coated with a very small quantity of mucilage, with gold or silver leaf, in a hollow spherical wooden box made by turning two hemispheres out of hard wood, fitting each other, and provided with a short handle.

It was proposed by Garot to cover pills with gelatin, which answers the purpose of concealing their taste and odor and counteracting deliquescence or chemical change from exposure to the air, but it sometimes interferes with their solubility in the stomach. This method of coating is largely used at the present time. One of the best machines that have been devised for gelatin coating pills is that of H. Maynard of Chicago. This consists of a circular plate in which are affixed twenty fine needles; the pills are rolled into depressions, and are easily impaled on the points of the needles; they are then dipped into a solution of gelatin, gently rotated, and allowed to cool. Another plan, less effectual, but more convenient, is to introduce the pills into a spherical box, to drop on them enough syrup simply to moisten their surface, then to give a rotary movement to the box until the pills are uniformly covered, and finally to add by degrees either powdered French chalk, elm bark, or some similar substance, shaking the box with each addition, and continuing the process until nothing more will adhere to the pills. The investing material may be ren-

dered agreeable to the taste and smell by aromatic additions, if deemed advisable. Calloud found that a good powder for coating pills, because little disposed to attract moisture, is made by boiling one part of flaxseed and three parts of white sugar with sufficient water until a thick mucilage is formed, evaporating this carefully to dryness, and then pulverizing. (*J. P. C.*, xxiii. 301.) The same writer has since suggested, as still more effective, a powder made by forming a mucilage with one part of tragacanth and two parts of water, pressing this through linen, mixing it with twenty parts of sugar of milk, spreading the paste thus made in thin layers to dry, and then powdering. The pills may be simply moistened with water and then shaken in the powder. L'hermite proposed first to agitate the pills in a mortar with a little concentrated solution of gum, and afterwards to put them into a box containing dry and very finely powdered sugar, to which a rotary motion is given. If the coating be not sufficiently thick, the process may be repeated. (*J. P. C.*, xxv. 460.) For a list of excipients for pills by J. Cohn see *Proc. A. Ph. A.*, 1900, 496 from *Ph. Ztg.*, 1900, 221.

The sugar coating of pills is now conducted upon a large scale by manufacturers, who send immense quantities both of popular and of official pills into the market thus protected. The process employed is similar to that of the confectioners in coating almonds. After having been thoroughly dried, the pills are put into a hemispherical tinned copper basin, which is suspended from the ceiling and moved quickly backward and forward with an eccentric motion, so as to cause a constant attrition among the pills. First a little very thick syrup, or syrup of gum, is introduced in order to give a thin coating to their surface, and afterwards very finely powdered and very dry white sugar is sifted or thrown over them, the motion being constantly maintained. The sugar is fixed by the moist surface of the pills, and the coating made compact and smooth by the attrition. The process is aided by a gentle heat, but the heat must be guarded, lest the pills be much softened, and thus lose their shape and even discolor the coating. Dexterous manipulation is necessary in order that the process may succeed thoroughly. For practical remarks on the sugar coating of pills, see an essay by H. C. Archibald in *A. J. P.*, 1867, p. 199, and by Wm. R. Warner, Jr., and T. S. Wiegand in *A. J. P.*, 1902, 32. On a larger scale a copper pill coater of peculiar construction, heated by steam pipes, is now used. Still another method, proposed by E. K. Durden, is to cover the pills with collodion, which completely conceals the taste. The solution employed by Durden had the sp. gr. 0.810, and two dippings gave a sufficient coating. (*A. J. P.*, xxi. 183.) It is, however, yet to be determined whether a coating of collodion would yield readily to the solvent powers of the gastric juice. Blanchard covers pills with

a solution of Tolu balsam in ether, but H. C. Baidon objects to this, that it takes too long to dry, and suggests as a substitute a solution of a drachm of the balsam in three drachms of chloroform, which dries sufficiently in twenty minutes. (*A. J. P.*, xxix. 350.) If old and solid Tolu balsam be selected, it will be less liable to the objection of drying slowly. This balsam is officially employed in coating the U. S. pills of ferrous iodide. A solution of mastic in ether has also been used for coating pills, and the white of egg has been recommended for the same purpose. (*Ibid.*, March, 1862, 137.) Pills are sometimes coated with substances which do not dissolve in the stomach, with the object of permitting the passage of the undissolved pill into the intestines; for this purpose keratin coating has been largely used. (See *Keratin*, PART II, and Remington's *Practice of Pharmacy*, Fourth edition, p. 1232.) *Salol* has also been employed, by melting it in an enamelled pan at a temperature of about 50° C. (132° F.) and dropping in the pills, rotating until covered, and then transferring to a dry pan, still rotating (to prevent adhesion) until cold. For further details, see *D. C.*, 1894, 123; *Ph. Ztg.*, xxxviii. 527.

Pills which are to be kept long should be well dried, and put into bottles with loosely fitting stoppers to prevent mouldiness. Though the U. S. Pharmacopœia, in almost every instance, orders the mass to be divided into pills, yet it should be understood rather as indicating the number of pills to be made from a certain quantity of the mass, when particular directions are not given by the physician, than as requiring the division to be made immediately after the materials have been mixed. It will be found convenient by the apothecary to retain a portion of the mass undivided, especially when it is desirable to keep the pills soft. The British Pharmacopœia furnishes formulas for pill masses, using the title of "Pilula" instead of "Massa," the title of the class adopted by the U. S. Pharmacopœia; there is, in our opinion, a decided advantage in selecting a name for the class which is not likely to be confused with that used for the divided pills.

Compressed pills are made directly from the medicinal substance without the aid of an excipient. The drug, if not already in granular powder, is made so, and then forced into pill shape by means of a powerful press. For certain substances which are crystalline in structure, such as quinine bisulphate, potassium bromide, and potassium iodide, and which have some cohesiveness and yet are of easy solubility, the process is a good one. An apparatus has been contrived by J. P. Remington for compressing pills (see 16th ed. U. S. D., and *Practice of Pharmacy*, 4th ed., page 1233). It is made of cast steel; the base has two countersunk depressions with a short post in the centre of each, and a lenticular depression

is made in the upper surface of each post. A steel cylinder having a central aperture of the diameter of the post is placed in the depression, the proper quantity of powder is introduced, and the plunger, which has a corresponding lenticular depression on its lower surface, is placed on the powder and is struck a quick blow with a mallet; the powder is compressed, and the pill adheres to the cylinder; by removing the cylinder and holding it over a box and tapping the plunger again lightly, the pill is forced out and falls into a box.

Compressed tablets are now used to an enormous extent, being made by various manufacturers with machinery of ingenious construction; the fact of their requiring no excipient, the ease with which they can be tested, and their permanent character (in most cases being just as valuable years after they were made as when fresh) have caused their extensive employment. Care should be taken, however, not to use them in those few cases where very prompt action is required, as the powerful compression to which they are subjected renders them less quickly effective than the same drug administered in the form of a loose powder.

PILULÆ ALOES. U. S. (Br.)

PILLS OF ALOES

(pil'ū-læ ā'lō-ēs)

Pilula Aloes Barbadosis, Br.; Pill of Barbados Aloes, Pill of Socotrine Aloes; Pilules d'Aloès et de Savon, *Fr. Cod.*; Pilules Aloétiques Savonneuses, *Fr.*; Aloepillen, *G.*

* "Purified Aloes, in fine powder, *thirteen grammes* [or 201 grains]; Soap, in fine powder, *thirteen grammes* [or 201 grains]; Water, a *sufficient quantity*, to make *one hundred pills*. Mix the powders intimately, then incorporate sufficient Water to form a mass, and divide it into *one hundred pills*." *U. S.*

"Barbados Aloes, in powder, 2 ounces (Imperial) or 40 grammes; Hard Soap in powder, 1 ounce (Imp.) or 20 grammes; Oil of Caraway, 1 fl. drachm (Imp. meas.) or 2.5 cubic centimetres; Confection of Roses, 1 ounce (Imp.) or 20 grammes or a sufficient quantity. Mix to form a mass." *Br.*

The former British process for *Pill of Socotrine Aloes* was the same except that Socotrine was substituted for Barbados Aloes, and the volatile Oil of Nutmeg for Oil of Caraway.

The soap, in this formula, not only serves to impart a proper consistence to the aloes, but is thought to qualify its operation and diminish its liability to irritate the rectum. Five of the U. S. pills, containing ten grains (0.65 Gm.) of aloes, may be given with a view to their purgative effect, but the preparation is usually employed as a laxative in *habitual costiveness*.

Dose, one, two or three pills at bedtime. The British pill mass is of very nearly the same strength as that of the U. S. Pharmacopœia.

PILULA ALOES ET ASAFETIDÆ.

Br.

PILLS OF ALOES AND ASAFETIDA

(pil'ù-là ãl'q-ēs ēt ās-a-fēt'ī-dæ)

Pilules d'Aloës et d'Asafétide, *Fr.*; Aloe- und Asafetida-Pillen, *G.*

A process for these pills was not retained in the U. S. P. (8th Rev.);¹ the British process is as follows:

"Socotrine Aloes, in powder, 1 ounce (Imperial) or 20 grammes; Asafetida, in powder, 1 ounce (Imp.) or 20 grammes; Hard Soap, in powder, 1 ounce (Imp.) or 20 grammes; Confection of Roses, 1 ounce (Imp.) or 20 grammes or a sufficient quantity. Mix to form a mass." *Br.*

Pills made from this mass are peculiarly adapted, by the stimulant and carminative properties of the asafetida, to cases of *costiveness* attended with flatulence and debility of the digestive organs.

Dose, about four grains (0.26 Gm.) of the mass.

PILULÆ ALOES ET FERRI. U. S.

(Br.)

PILLS OF ALOES AND IRON

(pil'ù-læ ãl'q-ēs ēt fēr'ri)

Pilula Aloes et Ferri, Br.; Pilulæ Italicæ Nigræ; Pilules d'Aloës et de Fer, *Fr.*; Pilulæ Aloeticæ ferratæ, *P. G.*; Eisenhaltige Aloepillen, Aloe- und Eisenpillen, Italienische Pillen, *G.*

* "Purified Aloes, in fine powder, seven grammes [or 108 grains]; Exsiccated Ferrous Sulphate, seven grammes [or 108 grains]; Aromatic Powder, seven grammes [or 108 grains]; Confection of Rose, a sufficient quantity, to make one hundred pills. Mix the powders intimately, then incorporate sufficient Confection of Rose to form a mass, and divide it into one hundred pills." *U. S.*

"Exsiccated Ferrous Sulphate, 1 ounce (Imperial) or 20 grammes; Barbados Aloes, in powder, 2 ounces (Imp.) or 40 grammes; Compound Powder of Cinnamon, 3 ounces (Imp.) or 60 grammes; Syrup of Glucose, 3 ounces (Imp.) or 60 grammes or a sufficient quantity. Mix to form a mass." *Br.*

This pill differs from the preparation of the same name in the British Pharmacopœia in the substitution of aromatic powder for the compound powder of cinnamon. It is essentially an old preparation of the Edinburgh Pharmacopœia, was omitted in the original British, and re-introduced and continued in the present edition. The *Br. Pharm.* 1898 improved this

mass by substituting exsiccated ferrous sulphate for the crystallized salt formerly employed, and by the use of syrup of glucose instead of confection of rose. It is said that the laxative power of aloes is increased, and its tendency to irritate the rectum diminished, by combination with ferrous sulphate. This pill is especially adapted to *amenorrhœa* with debility of the stomach and constipation.

Dose, from one to three pills.

PILULÆ ALOES ET MASTICHES.

U. S.

PILLS OF ALOES AND MASTIC [Lady Webster Pills]

(pil'ù-læ ãl'q-ēs ēt mäs'tī-chēs)

Lady Webster's Dinner Pills; Pilules d'Aloës et de Mastic, *Fr.*; Aloe- und Mastix-Pillen, *G.*

* "Purified Aloes, in fine powder, thirteen grammes [or 201 grains]; Mastic, in fine powder, four grammes [or 62 grains]; Red Rose, in fine powder, three grammes [or 46 grains]; Diluted Alcohol, a sufficient quantity, to make one hundred pills. Mix the powders intimately, then incorporate sufficient Diluted Alcohol to form a mass, and divide it into one hundred pills." *U. S.*

In the U. S. P. 1890 pill the proportion of mastic was slightly increased and that of red rose somewhat diminished. The same formula has been retained in the 8th Revision. Each of these pills contains about three grains of the solid ingredients and nearly two grains (0.13 Gm.) of aloes. They are in imitation of Lady Webster's dinner pills, and one of them may be given as a laxative at bedtime, or before a meal. The mastic has probably little other effect than to impair the solubility of the aloes, and thus give it a still greater tendency to act on the lower bowels.¹

Dose, one to three pills.

¹ The following is the formula for the aloetic pills usually called *dinner pills* or *Lady Webster's pills*. They are the *Pilule Stomachicæ* of the fifth edition of the *Parls. Codex*, 1758. Take of the best aloes six drachms; mastic and red roses, each, two drachms; syrup of wormwood sufficient to form a mass, to be divided into pills of three grains each. Common syrup may be used instead of syrup of wormwood. One or two of these pills, taken a short time before a meal, or at night, will usually produce one free evacuation.

The Philadelphia College of Pharmacy has adopted the following formulas for the compound aloetic preparations commonly called *Hooper's* and *Anderson's pills*:

"*Hooper's Female Pills*.—Barbados Aloes, 8 oz. troy; Exsiccated Ferrous Sulphate, 2 oz. troy, 90 grains (or Crystal Ferrous Sulphate, 4 oz. troy); Extract of Black Hellebore, 2 oz. troy; Myrrh, 2 oz. troy; Soap, 2 oz. troy; Canella, 1 oz. troy; Ginger, 1 oz. troy; all finely powdered. Beat the ingredients well together into a mass with water, and divide into pills, each containing two and a half grains." (*A. J. P.*, v. 25.)

"*Anderson's Scots Pills*.—Barbados Aloes, 24 oz. troy; Soap, 4 oz. troy; Colocynth, 1 oz. troy; Gamboge, 1 oz. troy; Oil of Anise, $\frac{1}{2}$ fluidounce. Let the aloes, colocynth, and gamboge be reduced to a very fine powder; then beat them and the soap with water into a mass, of a proper consistence to divide into pills, each containing three grains."

¹ *Pills of Aloes and Asafetida*, U. S. P. 1890. "Purified Aloes, in fine powder, nine grammes [or 139 grains]; Asafetida, nine grammes [or 139 grains]; Soap, in fine powder, nine grammes [or 139 grains]; Water, a sufficient quantity, to make one hundred pills. Beat the solids together with Water, so as to form a mass, and divide it into one hundred pills." *U. S.* 1890.

PILULÆ ALOES ET MYRRHÆ. U. S. (Br.)

PILLS OF ALOES AND MYRRH

(pil'ù-læ ãl'q-ēs ēt mÿr'r'hæ)

Pilulæ Aloes et Myrrhæ, Br.; Rufus's Pills; Pilules d'Aloës et de Myrrhe, Pilules de Rufus, Fr.; Ruffussche Pillen, G.

* "Purified Aloes, in fine powder, *thirteen grammes* [or 201 grains]; Myrrh, in fine powder, *six grammes* [or 93 grains]; Aromatic Powder, *four grammes* [or 62 grains]; Syrup, a *sufficient quantity*, to make *one hundred pills*. Mix the powders intimately, then incorporate sufficient Syrup to form a mass, and divide it into *one hundred pills*." U. S.

"Socotrine Aloes, in powder, 2 ounces (Imperial) or 40 grammes; Myrrh, in powder, 1 ounce (Imp.) or 20 grammes; Syrup of Glucose, 1½ ounces (Imp.) or 30 grammes or a sufficient quantity. Mix to form a mass." Br.

In the U. S. Pharm 1890 pill the proportion of myrrh was slightly decreased and that of aromatic powder somewhat increased. The formula has not been changed in the new Pharmacopœia. The Br. Pharm. 1898 dropped saffron, treacle, and glycerin from the formula used in former Pharmacopœias, and substituted for them syrup of glucose.

This composition has been long in use, under the name of *Rufus's Pills*. It is employed, as a warm stimulant cathartic, in *general debility* attended with *constipation*, and in *retention or suppression of the menses*.

Dose, three to six pills.

PILULA ALOES SOCOTRINÆ. Br.

PILL OF SOCOTRINE ALOES

(pil'ù-læ ãl'q-ēs sōc-ō-trī'næ)

"Socotrine Aloes, in powder, 2 ounces (Imperial) or 40 grammes; Hard Soap, in powder, 1 ounce (Imp.) or 20 grammes; Oil of Nutmeg, 1 fl. drachm (Imp. meas.) or 2.5 cubic centimetres; Confection of Roses, 1 ounce (Imp.) or 20 grammes or a sufficient quantity. Mix to form a mass." Br.

For properties and dose, see *Pilulæ Aloes*, p. 952.

PILULÆ ASAFÆTIDÆ. U. S.

PILLS OF ASAFETIDA

(pil'ù-læ äs-ä-fæt'id-æ)

Pilules d'Aséfétide, Fr.; Asafætida-Pillen, G.

* "Asafetida, *twenty grammes* [or 309 grains]; Soap, in fine powder, *six grammes* [or 93 grains]; Water, a *sufficient quantity*, to make *one hundred pills*. Beat the solids together with Water, so as to form a mass, and divide it into *one hundred pills*." U. S.

Each of these pills contains three grains (0.20 Gm.) of the gum-resin. They are a convenient form for administering asafetida, the unpleasant odor and taste of which render it very offensive in the liquid state.

Dose, one to three pills.

PILULA CAMBOGIÆ COMPOSITA.

Br.

COMPOUND PILL OF GAMBOGE

(pil'ù-læ çam-bō'gī-æ cōm-pōs'ī-tæ)

Pilules de Gomme-gutte composées, Fr.; Gummiguttpillenmasse, G.

"Gamboge, in powder, 1 ounce (Imperial) or 25 grammes; Barbados Aloes, in powder, 1 ounce (Imp.) or 25 grammes; Compound Powder of Cinnamon, 1 ounce (Imp.) or 25 grammes; Hard Soap, in powder, 2 ounces (Imp.) or 50 grammes; Syrup of Glucose, 1 ounce (Imp.) or 25 grammes or a sufficient quantity. Mix to form a mass." Br.

This is an active purgative pill, and may be given in the *dose* of from five to fifteen grains (0.32 to 1 Gm.). The simplified formula is that of George Fordyce.

PILULÆ CATHARTICÆ COMPOSITÆ. U. S.

COMPOUND CATHARTIC PILLS

(pil'ù-læ çä-thär'tī-çæ cōm-pōs'ī-tæ)

Antibilious Pills; Pilules cathartiques composées, Fr.; Abführpillen, G.

* "Compound Extract of Colocynth, *eighty grammes* [or 2 ounces av., 360 grains]; Mild Mercurous Chloride, *sixty grammes* [or 2 ounces av., 51 grains]; Resin of Jalap, in fine powder, *twenty grammes* [or 309 grains]; Gamboge, in fine powder, *fifteen grammes* [or 231 grains]; Diluted Alcohol, a *sufficient quantity*, to make *one thousand pills*. Mix the powders intimately, then incorporate a sufficient quantity of Diluted Alcohol to form a mass, and divide it into *one thousand pills*." U. S.

This cathartic compound was first made official in the second edition of the U. S. Pharmacopœia. It was intended to combine smallness of bulk with efficiency and comparative mildness of purgative action and a peculiar tendency to the biliary organs. Such an official preparation was much wanted in this country, in which bilious fevers, and other complaints attended with congestion of the liver and portal circle generally, so much abound. The object of smallness of bulk is accomplished by employing extracts and the more energetic cathartics; that of a peculiar tendency to the liver, by the use of calomel, and that of efficiency with mildness of operation, by the union of several powerful purgatives. It is a fact, abundantly proved by experience, that drastic cathartics become milder by com-

bination, without losing any of their purgative power. Nor is it difficult, in this case, to reconcile the result of observation with physiological principles. Cathartic medicines act on different parts of the alimentary canal and organs secreting into it. In small doses, both the irritation which they occasion and their purgative effect are proportionately lessened. If several are administered at the same time, each in a diminished dose, it is obvious that the combined purgative effect of all will be experienced, while the irritation, being feeble in each part affected, and diffused over a large space, will be less sensible to the patient, and will more readily subside. In the compound cathartic pills, most of the active purgatives in common use are associated together in proportions corresponding with their respective doses, so that an excess of any one ingredient is guarded against, and violent irritation from this cause prevented. The present official process does not differ from that of the U. S. P. 1890, except in the substitution of the resin of jalap for the extract, the latter being no longer official, and in the use of diluted alcohol as an excipient in place of water. This, however, does not alter the composition, and it makes a smaller pill. It is highly important for the efficiency of these pills that they be prepared in exact compliance with the directions, and that the *compound extract of colocynth* and the *resin of jalap* used be of good quality. When they fail, the result is generally ascribable to the substitution of jalap for the resin, or to the use of a compound extract of colocynth made with nearly inert scammony, inferior aloes, and insufficient colocynth, and altogether badly prepared. (See a paper by G. H. Chas. Klie, *A. J. P.*, April, 1878.)

Each pill weighs about 3 grains (0.194 Gm.), and contains 2.70 grains (0.175 Gm.) of active ingredients. A single pill will generally be found to operate as a mild laxative. In a full dose, the preparation acts vigorously on the bowels, producing bilious stools, generally without much pain or disorder of the stomach. It may be employed in most instances where a brisk cathartic is required, but is particularly applicable to the early stages of *bilious fevers*, to *hepatitis*, *jaundice*, and all those derangements which depend on congestion of the portal circle.

Dose, one to three pills.

PILULÆ CATHARTICÆ VEGETABILES. U. S.

VEGETABLE CATHARTIC PILLS

(pil'û-læ ca-thär'ti-çæ vëg-ë-täb'l-lës)

Pilules cathartiques végétales, *Fr.*; Vegetabilische Abführpillen, *G.*

* "Compound Extract of Colocynth, *sixty grammes* [or 2 ounces av., 51 grains]; Extract of Hyoscyamus, *thirty grammes* [or 1 ounce av., 25 grains]; Resin of Jalap, in fine

powder, *twenty grammes* [or 309 grains]; Extract of Leptandra, *fifteen grammes* [or 231 grains]; Resin of Podophyllum, *fifteen grammes* [or 231 grains]; Oil of Peppermint, *eight cubic centimeters* [or 130 minims]; Diluted Alcohol, a *sufficient quantity*, to make *one thousand pills*. Mix the Compound Extract of Colocynth intimately with the Resin of Podophyllum, Resin of Jalap, and Extract of Leptandra, and then add the Oil of Peppermint. Rub the Extract of Hyoscyamus with enough Diluted Alcohol to render it plastic, then incorporate it with the mixture first prepared, using a sufficient quantity of Diluted Alcohol to form a mass, and divide it into *one thousand pills*." U. S.

This pill was introduced into the U. S. P. 1890 with the view of furnishing a formula for a cathartic pill without a mercurial. The U. S. P. (8th Rev.) process substituted resin of jalap for the extract and diluted alcohol for water as in the compound cathartic pill (see above). The oil of peppermint and extract of hyoscyamus are added to the cathartics to prevent griping. The dose is three pills, and they may be given in the place of compound cathartic pills.

Dose, one to three pills.

PILULA COLOCYNTHIDIS COMPOSITA. Br.

COMPOUND PILL OF COLOCYNTH

(pil'û-lä cöl-q-cyn'thî-dis com-pös'î-tä)

Cochia Pills; Pilules de Coloquinte composées, *Fr.* *Cod.*; Pilules cochées mineures, *Fr.*; Zusammengesetzte Koloquinten-Pillen, *G.*

"Colocynth Pulp, in powder, 1 ounce (Imperial) or 20 grammes; Barbados Aloes, in powder, 2 ounces (Imp.) or 40 grammes; Scammony Resin, in powder, 2 ounces (Imp.) or 40 grammes; Potassium Sulphate, in very fine powder, $\frac{1}{2}$ ounce (Imp.) or 5 grammes; Oil of Cloves, 2 fl. drachms (Imp. meas.) or 5 cubic centimetres; Distilled Water, a *sufficient quantity*. Triturate the Oil of Cloves with the Potassium Sulphate; add the Colocynth Pulp; mix; add the Barbados Aloes and Scammony Resin; after mixing intimately add the Distilled Water and beat to form a mass." Br.

This is not, like the old London pills of the same name, merely another form of the compound extract of colocynth, though containing essentially the same materials,—one great difference being that colocynth and aloes are used in substance in the pill, instead of in the state of extract. Potassium sulphate is used to promote the more complete division of the aloes and scammony. The preparation is actively cathartic.

Dose, from five to twenty grains (0.32 to 1.3 Gm.).

Off. Prep.—Pilula Colocynthis et Hyoscyami, Br.

PILULA COLOCYNTHIDIS ET HYOSCYAMI. Br.

PILL OF COLOCYNTH AND HYOSCYAMUS

(pil'ŭ-lă cōl-o-cyn'thī-dis ēt hī-ōs-cy'ā-mī)

Pilules de Coloquinte et d'Extrait de Jusquiamé, Fr.; Koloquinten-Bilsenkrautpillenmasse, G.

"Compound Pill of Colocynth, 2 ounces (Imperial) or 50 grammes; Extract of Hyoscyamus, 1 ounce (Imp.) or 25 grammes. Mix to form a mass." Br.

This was an official pill of the Edinburgh College. It is asserted that the compound pill and compound extract of colocynth are almost entirely deprived of their griping tendency by combination, as above, with extract of hyoscyamus, without losing any of their purgative power.

Dose, from five to twenty grains (0.32 to 1.3 Gm.).

PILULÆ FERRI CARBONATIS. U. S. (Br.)

PILLS OF FERROUS CARBONATE [Ferruginous Pills, Chalybeate Pills, Bland's Pills]

(pil'ŭ-læ fēr'ri cār-bō-nā'tis)

Pilula Ferri, Br.; Iron Pill; Pilules Ferrugineuses de Bland, Fr. Od.; Pilules Chalybées de Bland, Fr.; Pilulæ Ferri carbonici Blandii, P. G.; Blandsche Pillen, G.; Pillole di carbonato ferroso, It.; Pildoras de Bland, Sp.

* "Granulated Ferrous Sulphate, sixteen grammes [or 247 grains]; Potassium Carbonate, eight grammes [or 123 grains]; Sugar, four grammes [or 62 grains]; Tragacanth, in fine powder, one gramme [or 15.5 grains]; Althæa, in No. 60 powder, one gramme [or 15.5 grains]; Glycerin, Water, each, a sufficient quantity, to make one hundred pills. Rub the Potassium Carbonate, in a mortar, with a sufficient quantity (about ten drops each) of Glycerin and Water, then add the Ferrous Sulphate and Sugar, previously triturated together to a uniform powder, and rub the mass thoroughly, until it assumes a greenish color. When the reaction has terminated, incorporate the Tragacanth and Althæa, and, if necessary, add a little more Water, so as to obtain a mass of pilular consistence. Divide this into one hundred pills. These pills should be freshly prepared when wanted." U. S.

"Exsiccated Ferrous Sulphate, in fine powder, 150 grains or 15 grammes; Exsiccated Sodium Carbonate, in fine powder, 95 grains or 9.5 grammes; Gum Acacia, in powder, 50 grains or 5 grammes; Tragacanth, in powder, 15 grains or 1.5 grammes; Syrup, 150 grains or 15 grammes; Glycerin, 10 grains or 1 gramme; Distilled Water, 20 grains or 2 grammes or a sufficient quantity. To the Syrup, Glycerin, and Distilled Water, previously mixed, add the Ferrous Sulphate; mix; add quickly the Sodium Carbonate; mix; set aside for fifteen minutes, or until the reaction is complete; add the Gum Acacia and Tragacanth, and incorporate

thoroughly. If divided into five-grain pills, each pill will contain about 1 grain of ferrous carbonate." Br.

In the Br. Pharm. 1898 exsiccated ferrous sulphate and sodium carbonate replace the crystallized salts of the former authority.

In the U. S. P. 1890 the name of this pill was changed to *Pilula Ferri Carbonatis* and the *Pilula Ferri Composita* of the U. S. P. 1880 was dropped,¹ which sometimes led to a complication; the U. S. P. 1890 title was retained in the U. S. P. (8th Rev.) as it would lead to confusion to change the name again. It should be remembered, however, that "pills of ferrous carbonate" no longer means pills made from Vallet's Mass but Bland's pills. Dunning and Hynson (*Proc. A. Ph. A.*, 1901, 177) prefer the formula given in the footnote for these pills.²

These pills are closely analogous to the *Mistura Ferri Composita* in properties and composition. They form a good emmenagogue and chalybeate tonic. As their peculiar advantages depend upon the presence of ferrous carbonate, which speedily changes into the ferric salt on exposure, it is proper that only so much of the mass should be prepared as may be wanted for immediate use. They are sometimes called *Griffith's pills*. They closely resemble *Bland's ferruginous pills*, made originally in 1831, and celebrated in France as a remedy in *chlorosis*, prepared from equal weights of ferrous sulphate and potassium carbonate, made into a pilular mass. (See *P. J.*, 1894, 131.) The pills contain, as the result of double decomposition, ferrous carbonate and potassium sulphate. Van de Velde and Van Melckebeke prefer the sodium bicarbonate to the potassium salt. For a brief historical account of these pills see a paper by John Humphrey in *P. J.*, 1903, 643.

Dose, from two to six pills, to be taken three times a day.

¹ *Pilula Ferri Composita*, Compound Pills of Iron. "Myrrh, in fine powder, one hundred and fifty grains (9.75 Gm.); Carbonate of Sodium, seventy-five grains (4.85 Gm.); Sulphate of Iron, seventy-five grains (4.85 Gm.); Syrup, a sufficient quantity, to make one hundred pills. Rub the Myrrh, first with the Carbonate of Sodium and afterward with the Sulphate of Iron, until they are thoroughly mixed; then beat them with Syrup so as to form a mass, and divide it into one hundred pills." U. S. 1880.

² Ferrous sulphate, in clear crystals, 240 grains; potassium carbonate, 140 grains; sugar, 20 grains; licorice root, powdered, 100 grains; glucose, sufficient quantity; the following directions for preparation must be closely observed: Rub the ferrous sulphate into fine powder with the sugar, and mix with the potassium carbonate, previously powdered; then rub these mixed powders to a smooth paste, continuing until an almost dry powder results; add the powdered licorice root, and thoroughly mix; mass with glucose, being careful to use sufficient of the latter. Continue the working of mass until it becomes solid and of good pilular consistence, being especially careful that it is kneaded until there is no swelling of the mass. Roll out at leisure. The large amount of glucose not only prevents the pills from oxidizing, but also tends to keep them soft, while, apparently, not increasing their size.

England's formula for Bland's Pills (*Phila. Med. Journ.*, Jan. 28, 1899) is as follows: Mass of ferrous carbonate, 36 grains; Potassium sulphate, 24 grains; Potassium carbonate, 4 grains; Powdered althea, 1 grain; Powdered acacia, sufficient. Make into 12 pills, and enclose in No. 4 gelatin capsules.

PILULÆ FERRI IODIDI. U. S.

PILLS OF FERROUS IODIDE

(pil'ù-læ fër'rî i-ôd'î-di)

Pilules d'Iodure ferreux, *Fr. Cod.*; Pilules de Blancard, *Fr.*; Eisenjodürpillen, *G.*; Pilule di protojoduro di ferro, *It.*; Píldoras de yoduro ferroso, *Sp.*

* "Reduced Iron, four grammes [or 62 grains]; Iodine, five grammes [or 77 grains]; Glycyrrhiza, in No. 60 powder, four grammes [or 62 grains]; Sugar, in fine powder, four grammes [or 62 grains]; Extract of Glycyrrhiza, in fine powder, one gramme [or 15.5 grains]; Acacia, in fine powder, one gramme [or 15.5 grains]; Water, Balsam of Tolu, Ether, each, a sufficient quantity, to make one hundred pills. To the Reduced Iron, contained in a small mortar, add six cubic centimeters [or 97 minims] of Water, and then, gradually, the Iodine with constant stirring, until the liquid ceases to have a reddish tint. Then add the remaining powders, previously well triturated together, and mix the whole thoroughly. Transfer the mass to a porcelain dish, and evaporate the excess of moisture, on a water-bath, with constant stirring, until the mass has acquired a pilular consistence. Then divide it into one hundred pills. Dissolve ten grammes [or 154 grains] of Balsam of Tolu in fifteen cubic centimeters [or 243 minims] of Ether, shake the pills with a sufficient quantity of this solution until they are uniformly coated, and put them on a plate to dry, occasionally rolling them about until the drying is completed. Keep the pills in a well-stoppered bottle. Pills of Ferrous Iodide should be devoid of the smell of iodine. If a few of the pills be triturated with water, and the liquid filtered, the filtrate should not assume more than a light blue tint upon the addition of starch T.S. (absence of more than traces of free iodine)." U. S.

This process does not differ essentially from that formerly official.¹

¹ *Pills of Ferrous Iodide.*—Wm. R. Warner, Jr.'s, *Process.*—Take of iodine 4634 grains; iron wire 1600 grains; sugar 4500 grains; marshmallow powder 4500 grains; gum 2200 grains; iron by hydrogen 566 grains; distilled water 3000 grains. Place the iron wire in a Florence flask, quart capacity, add the water, place on a sand bath, and gently heat; then add the iodine in such divided portions as the reaction will admit of, without raising the temperature so high as to drive off the violet fumes of iodine. Finally, add all the iodine, and continue the heat until the reaction has ceased, and the liquid shows no blue color with starch macilage. The weight of the flask must be previously determined, and at this point the weight of the contents should be 9234 grains; if not, sufficient water must be added to make it so. Now mix thoroughly together the gum, sugar, marshmallow, and iron by hydrogen, and strain upon them the contents of the flask; mix quickly, and knead thoroughly, until a pill mass is formed, then divide it into three-grain pills, each containing one grain of ferrous iodide (iodine, iron, and water of crystallization). The pills, after being hardened in a warm, dry atmosphere, covered with starch powder, may be coated with a solution of gum mastic in ether or tolu in alcohol, in the proportion of four drachms to the fluidounce. An *extemporaneous* sugar coating may be effected to a reasonable degree of perfection in the following manner. Mix together

The pills of ferrous iodide were introduced into the U. S. Pharmacopœia at the revision of 1850. The present official pills are formed on the plan proposed by Procter, in imitation of *Blancard's pills* (*A. J. P.*, May, 1860), and are much superior to those made by the U. S. process of 1850, or by that of the British Pharm. 1885. Magnes-Lahens especially recommended the following formula: "Take of pure Iodine 4.10 grammes; Powdered Iron 1.90 grammes; Powdered Sugar 2.50 grammes; Powdered Gum Arabic 2.50 grammes; Distilled Water 2.50 grammes. Put in an iron dish the Water and the powdered Iron, add the Iodine gradually, and facilitate the reaction by stirring with a spatula of iron and by warming a little; when the reaction is complete, add the Gum and the Sugar, then heat to about 50° C. (122° F.), stirring until the mass ceases to drop when a little is taken up on the spatula. If necessary, five grammes of powdered licorice root may be incorporated into the mass, which is then to be rolled into one hundred pills." (*A. J. P.*, 1873, p. 498.) The iodine and iron unite directly to form ferrous iodide in solution, which is protected against the oxidizing influence of the air by the sugar and excess of reduced iron, while the licorice and gum serve to give due consistence and plasticity to the pilular mass. The pills are still further protected from the air by the impervious coating of balsam of Tolu, which readily yields to the softening and solvent properties of the gastric liquids. The great disadvantage of the pill of ferrous iodide, as ordinarily prepared, is that it will not keep,—crumbling by time and exposure, and evolving iodine in consequence of the oxidation of the iron. The preparation, made according to the U. S. formula of 1870, stood the test of time, and we have seen pills which, four years after their preparation, exhibited no signs of change. Each pill contains about a grain (0.065 Gm.) of ferrous iodide and two-fifths of a grain (0.024 Gm.) of reduced iron. The therapeutic uses of this preparation are the same as those of ferrous iodide. (See *Ferri Iodidum*.)

Dose, one to three pills.

PILULA GALBANI COMPOSITA. Br.

COMPOUND PILL OF GALBANUM
[Compound Pill of Asafetida]

(pil'ù-là gâl'ba-nî côm-pôs'î-tà)

Pilules de Galbanum composées, *Fr.*; Galbanumpillemasse, *G.*

"Asafetida, 2 ounces (Imperial) or 50 grammes; Galbanum, 2 ounces (Imp.) or 50 grammes; Myrrh, 2 ounces (Imp.) or 50 grammes;

thoroughly equal quantities of sugar, gum, and starch. Moisten the surface of the pills with an equal mixture of simple syrup and water, and then place them on the powder in a shallow dish, and give the same a centrifugal motion, so that they may be equally coated by the moisture of the syrup, which will agglutinate the particles of the powder. (*D. C.*, 1884, p. 4.)

Syrup of Glucose, 1 ounce (Imp.) or 25 grammes or a sufficient quantity. Heat all together on a water-bath, stirring until the mass is uniform in consistence." Br. This mass was formerly termed in the British Pharmacopœia *Pilula Asafetide Composita*. The treacle used as an excipient has been replaced by syrup of glucose. It is given as an antispasmodic and emmenagogue in *chlorosis* and *hysteria*.

Dose, from two to four pills or from five to twenty grains (0.32 to 1.3 Gm.).¹

PILULA HYDRARGYRI SUBCHLORIDI COMPOSITA. Br.

COMPOUND PILL OF MERCUROUS CHLORIDE

(pil'ù-là hy-dràr'gy-rì sub-chlò'rj-di còm-pòs'ì-tà)

Pilulæ Antimonii Compositæ, U. S. 1890; Compound Pills of Antimony, Plummer's Pills; *Pilula Calomelanos Composita*, Br. 1864; Compound Pill of Mercurous Chloride, Compound Calomel Pill; *Pilules altérantes composées*, *Pilules antidartreuses*, *Pilules de Plummer*, Fr.; Plummer'sche Pillen, Zusammen-gesetzte Calomelpillen, G.

"Mercurous Chloride, 1 ounce (Imperial) or 25 grammes; Sulphurated Antimony, 1 ounce (Imp.) or 25 grammes; Guaiacum Resin, in powder, 2 ounces (Imp.) or 50 grammes; Castor Oil, 180 grains or 10.3 grammes; Alcohol (90 per cent.), 1 fl. drachm (Imp. meas.) or 3 cubic centimetres or a sufficient quantity. Mix to form a mass." Br.

Compound pills of antimony were dropped in the U. S. P. (8th Rev.); the formula for this pill in the U. S. P. 1890² was altered by adopting the British method of using castor oil as an excipient instead of mucilage of tragacanth; this change was of doubtful utility, the pills when kept acquiring an unpleasant odor. The oil is, however, a partial solvent for the guaiac.

We prefer the title "Compound Calomel Pill" of the former British Pharmacopœia, as not liable to any mistake, and as most expressive of the quality of the medicine. The antimonial employed, though under a different name, is identical with the old U. S. precipitated sulphide. According to Vogel a reaction takes place between the calomel and the sulphurated antimony, resulting in the production of antimony chloride and mercury sulphide. The preparation was originally introduced to the notice of the profession by Dr. Plummer,

¹ The U. S. P. 1880 gave the following formula for this preparation: "Galbanum, one hundred and fifty grains (9.75 Gm.); Myrrh, one hundred and fifty grains (9.75 Gm.); Asafetida, fifty grains (3.25 Gm.); Syrup, a sufficient quantity, to make one hundred pills. Beat them together so as to form a mass, and divide it into one hundred pills."

² *Pilulæ Antimonii Compositæ*, U. S. 1890. Compound Pills of Antimony, Plummer's Pills.—"Sulphurated Antimony, four grammes [or 62 grains]; Mild Mercurous Chloride, four grammes [or 62 grains]; Gualac, in fine powder, eight grammes [or 123 grains]; Castor Oil, a sufficient quantity, to make one hundred pills. Beat the powders together with the Castor Oil, added a few drops at a time, so as to form a mass, and divide it into one hundred pills." U. S. 1890.

who found it useful as an alterative, and upon whose authority it was at one time much employed under the name of *Plummer's Pills*. The combination is well adapted to the treatment of *chronic rheumatism* and of *scaly* and other *eruptive diseases of the skin*, especially when accompanied with a syphilitic taint.

Dose, four to eight grains (0.26 to 0.5 Gm.) or more, morning and evening.

PILULA IPECACUANHÆ CUM SCILLA. Br.

PILL OF IPECACUANHA WITH SQUILL

(pil'ù-là ip-è-các-ù-àn'hæ cùm scil'là)

Pilules d'Ipecacuanha et de Scille, Fr.; Brech-wurzel-Meerzwiebelpillen, G.

"Compound Powder of Ipecacuanha, 3 ounces (Imperial) or 30 grammes; Squill, in powder, 1 ounce (Imp.) or 10 grammes; Ammoniacum, in powder, 1 ounce (Imp.) or 10 grammes; Syrup of Glucose, a sufficient quantity. Mix to form a mass. This Pill contains about 5 per cent. of Opium." Br.

This is a good combination of expectorants, well adapted to *chronic bronchitis* with either deficient or greatly excessive expectoration, and to the advanced stages of the acute disease offering similar indications.

Dose, from five to ten grains (0.32 to 0.65 Gm.).

PILULÆ LAXATIVÆ COMPOSITÆ.

U. S.

COMPOUND LAXATIVE PILLS

(pil'ù-læ lăx-a-tîvæ còm-pòs'ì-tæ)

Pilulæ Aloini, Belladonnæ et Strychninæ Compositæ; Compound Pills of Aloin, Belladonna and Strychnine; *Pilules laxatives composées*, Fr.; Zusammen-gesetzte Laxirpillen, G.

* "Aloin, one and three-tenths grammes [or 20 grains]; Strychnine, five-hundredths of a gramme [or $\frac{1}{2}$ grain]; Extract of Belladonna Leaves, eight-tenths of a gramme [or 12.3 grains]; Ipecac, in fine powder, four-tenths of a gramme [or 6.1 grains]; Glycyrrhiza, in fine powder, four and six-tenths grammes [or 71 grains]; Syrup, a sufficient quantity, to make one hundred pills. Triturate the Aloin, Strychnine, Ipecac, and Glycyrrhiza together thoroughly, so as to produce a uniform powder. Incorporate with this the Extract of Belladonna Leaves and sufficient Syrup to form a mass, and divide it into one hundred pills." U. S.

This pill was introduced into the U. S. P. (8th Rev.) because of its large use in the United States. Each pill contains one-fifth of a grain of aloin, one hundred and thirtieth of a grain of strychnine, one-eighth of a grain of extract of belladonna leaves, one-sixteenth of a grain of ipecac, and three-fourths of a grain of powdered licorice root.

Uses.—As its name indicates, this pill is used as a laxative; similar pills are known as *A. B. S. pills, lapactic pills, evacuant pills.*

Dose, one or two pills at night.

PILULÆ OPII. U. S. (Br.)

PILLS OF OPIUM

(pil'û-læ ô'pî-i)

Pilula Saponis Composita, Br.; Compound Pill of Soap; **Pilules d'Opium, Fr.;** Opiumpillen, G.

* "Powdered Opium, *six and one-half grammes* [or 100 grains]; Soap, in fine powder, *two grammes* [or 31 grains]; Water, a *sufficient quantity*, to make *one hundred pills*. Mix the powders intimately, then incorporate sufficient Water to form a mass, and divide it into *one hundred pills.*" *U. S.*

This process is designated merely to furnish a convenient formula for putting opium into pilular form, preferable to the mode sometimes practised of making the pills directly from the unpowdered mass of opium as found in commerce. The soap answers no other purpose than to give a due consistence, and is therefore in small proportion. Opium pills are official in the British Pharmacopœia under the name of *Pilula Saponis Composita* (see page 961). The object of giving them this title is probably to prevent the patient from learning from the prescription that the pills contain opium. As hard old opium pills are sometimes preferred, in cases of irritable stomach, in consequence of their slow solution, it is proper for the pharmacist to keep some in this state to meet the prescription of the physician. Of the pills above directed, each contains one grain (0.065 Gm.) of powdered opium.

Dose, one pill.

PILULÆ PHOSPHORI. U. S. (Br.)

PILLS OF PHOSPHORUS

(pil'û-læ phôs'phô-rî)

Pilula Phosphori, Br.; Phosphorus Pill; **Pilules au Phosphore, Pilules Phosphorées, Fr.;** Phosphoripillen, G.

* "Phosphorus, *six-hundredths of a gramme* [or 0.93 grains]; Althæa, in No. 60 powder, *six grammes* [or 93 grains]; Acacia, in fine powder, *three grammes* [or 46 grains]; Chloroform, Glycerin, Water, Balsam of Tolu, Ether, each, a *sufficient quantity*, to make *one hundred pills*. Dissolve the Phosphorus, in a test-tube, in *five cubic centimeters* [or 81 minims] of Chloroform, with the aid of a very gentle heat, replacing from time to time any of the Chloroform which may be lost by evaporation. Mix the Althæa and Acacia in a mortar, next add the solution of Phosphorus, then immediately afterwards a sufficient quantity (about *four cubic centimeters* [or 65 minims]) of a mixture of *two volumes* of Glycerin and *one volume* of Water, and quickly form a mass;

divide it into *one hundred pills*. Dissolve *ten grammes* [or 154 grains] of Balsam of Tolu in *fifteen cubic centimeters* [or 243 minims] of Ether, shake the pills with a sufficient quantity of this solution until they are uniformly coated, and put them on a plate to dry, occasionally rolling them about until the drying is completed. Keep the pills in a well-stoppered bottle." *U. S.*

"Phosphorus, 10 *grains* or 1 gramme; White Beeswax, melted, 125 *grains* or 12.5 grammes; Lard, melted, 125 *grains* or 12.5 grammes; Kaolin, 115 *grains* or 11.5 grammes; Carbon Bisulphide, 33 *minims* or 3 cubic centimetres or a sufficient quantity. Place the melted Wax and Lard in a slightly warmed mortar, and stir until the mixture has the consistence of cream. Dissolve the Phosphorus in the Carbon Bisulphide and carefully mix the solution with the melted fats; add the Kaolin; mix well together. Keep the mixture immersed in cold water in a bottle from which the light is excluded. When dispensed, every *three grains* of the mixture is to be incorporated with *one grain* of Gum Acacia in powder; and the resulting pills should be varnished. Phosphorus Pill, including the Gum Acacia, contains 2 per cent. of Phosphorus; hence, is nearly double the strength of the Phosphorus Pill of the British Pharmacopœia of 1885." *Br.*

The increasing use of phosphorus in the free state made the introduction of phosphorus pills a necessity. The problem of preventing the oxidation of the phosphorus is believed to be solved by dissolving it in an excess of warm chloroform; this is accomplished in a stoppered test-tube, for it has been shown that no oxidation takes place in the presence of chloroform vapor. It is necessary to form the mass quickly, so that the chloroform may not all evaporate and leave the phosphorus exposed to the action of the air. Chloroform is preferred to carbon disulphide, for, although the latter is a better solvent, it is difficult to rid the mass of the disgusting odor. (See *A. J. P.*, 1875, 253, 254, 335, 501; 1876, 56; 1877, 135; 1878, 584; and *N. R.*, 1876, 189, 332; 1877, 32; *D. C.*, 1883, 180; *P. J.*, 1883, 923.)

Dose, of the British mass, four grains of the mass, including the acacia, will contain 1-12th of a grain of phosphorus (0.005 Gm.), and the *dose* is therefore one-half grain (0.032 Gm.), equivalent to 1-96th of a grain (0.0007 Gm.) of phosphorus. Each official U. S. pill contains about 1-100th of a grain (0.0006 Gm.) of phosphorus.

PILULA PLUMBI CUM OPIO. Br.

PILL OF LEAD WITH OPIUM

(pil'û-lâ plûm'bi cûm ô'pî-ô)

Pilules d'Acétate de Plomb et d'Opium, Fr.; Bleiacetat-Opiumpillenmasse, G.

"Lead Acetate, in fine powder, 36 *grains* or 6 grammes; Opium, in powder, 6 *grains* or 1

gramme; Syrup of Glucose, 4 grains or 0.7 gramme or a sufficient quantity. Mix to form a mass. This Pill contains about 12½ per cent. of Opium." *Br.*

This pill would be better left to extemporaneous prescription, the requisite proportion of opium to the acetate varying in different cases. Syrup of glucose has been substituted in the 1898 revision for confection of roses, the latter being incompatible with lead acetate. The mass contains about six parts of lead acetate in eight.

Dose, two or three grains (0.13 or 0.20 Gm.) to begin with.

PILULÆ PODOPHYLLI, BELLADONNÆ ET CAPSICI. U. S.

PILLS OF PODOPHYLLUM, BELLADONNA AND CAPSICUM

(pil'ù-læ pò-dò-phýl'lî bél-là-dôn'næ èt càp'sî-tî)

Pilules de Podophyllum, de Belladone et de Polvre de Guinée, *Fr.*; Podophyllin-, Belladonna-, und Spanisch-Pfefferpillen, *G.*

* "Resin of Podophyllum, one and six-tenths grammes [or 25 grains]; Extract of Belladonna Leaves, eight-tenths of a gramme [or 12 grains]; Capsicum, in moderately fine powder, three and two-tenths grammes [or 49 grains]; Sugar of Milk, in fine powder, six and one-half grammes [or 100 grains]; Acacia, in fine powder, one and sixth-tenths grammes [or 25 grains]; Glycerin, Syrup, each, a sufficient quantity, to make one hundred pills. Triturate the Resin of Podophyllum, Capsicum, Sugar of Milk, and Acacia together to produce a uniform powder. Incorporate with this the Extract of Belladonna Leaves and sufficient of a mixture of equal parts of Glycerin and Syrup to form a mass; divide it into one hundred pills." *U. S.*

This pill is largely used and is based upon the formula proposed by E. R. Squibb. It was introduced into the U. S. P. (8th Rev.) for the first time. Each pill contains about one-fourth of a grain of resin of podophyllum, one-eighth of a grain of extract of belladonna leaves, one-half of a grain of powdered capsicum, sugar of milk, acacia, glycerin, and syrup.

Uses.—These pills afford an excellent means of obtaining the laxative effect of podophyllum.

Dose, one to two pills.

PILULA QUININÆ SULPHATIS. Br.

PILL OF QUININE SULPHATE

(pil'ù-là quî-nî'næ sùl-phā'tîs)

Pilule de Quinine Sulfate, *Fr.*; Chininpillenmasse, *G.*; Pilulas de sulfato quínico, *Sp.*

"Quinine Sulphate, 30 grains or 3 grammes; Tartaric Acid, in powder, 1 grain or 0.1 gramme; Glycerin, 4 grains or 0.4 gramme; Tragacanth, in powder, 1 grain or 0.1 gramme. Triturate the Quinine Sulphate with the Tar-

taric Acid; add the product to the previously mixed Glycerin and Tragacanth; make a mass." *Br.*

The reason for introducing a quinine pill mass in the British Pharm. 1898 is doubtless to serve the convenience of dispensers and to save time; tartaric acid aids in solubility and in making the pills smaller, while glycerin keeps the mass from undue hardening.

Dose, two to eight grains (0.13 to 0.5 Gm.).

PILULÆ RHEI COMPOSITÆ. U. S.

(*Br.*)

COMPOUND PILLS OF RHUBARB

(pil'ù-læ rhē'i còm-pòs'î-tæ)

Pilula Rhei Composita, Br.; Pilules de Rhubarbe composées, *Fr.*; Rhabarber und Aloepillen, *G.*

* "Rhubarb, in No. 60 powder, thirteen grammes [or 201 grains]; Purified Aloes, in fine powder, ten grammes [or 154 grains]; Myrrh, in fine powder, six grammes [or 93 grains]; Oil of Peppermint, one-half cubic centimeter [or 8 minims]; Water, a sufficient quantity, to make one hundred pills. Mix the Oil of Peppermint intimately with the powders, then incorporate sufficient Water to form a mass; divide it into one hundred pills." *U. S.*

"Rhubarb Root, in powder, 3 ounces (Imperial) or 60 grammes; Socotrine Aloes, in powder, 2½ ounces (Imp.) or 45 grammes; Myrrh, in powder, 1½ ounces (Imp.) or 30 grammes; Hard Soap, in powder, 1½ ounces (Imp.) or 30 grammes; Oil of Peppermint, 1½ fl. drachms (Imp. meas.) or 3.75 cubic centimetres; Syrup of Glucose, 2½ ounces (Imp.) or 55 grammes or a sufficient quantity. Mix to form a mass." *Br.*

This is a warm tonic laxative, useful in costiveness. If made in quantity the pills should be kept in loosely stoppered bottles. The use of glycerin favors the formation of mouldiness through the attraction of moisture, and it was replaced in the formula of the *Br. Ph.* 1898 by syrup of glucose. Rhubarb pills (*Pilulæ Rhei*, *U. S.* 1890) were not admitted to the U. S. P. (8th Rev.); the formula is appended.¹

Dose, of the compound rhubarb pills, two to four pills, or from ten to twenty grains (0.65 to 1.3 Gm.) of the mass, twice a day.

¹ *Pilulæ Rhei, U. S.* 1890, *Pills of Rhubarb*. "Rhubarb, in No. 60 powder, twenty grammes [or 308 grains]; Soap, in fine powder, six grammes [or 93 grains]; Water, a sufficient quantity, to make one hundred pills. Beat the powders together with Water, so as to form a mass, to be divided into one hundred pills." *U. S.* 1890.

Rhubarb is so often given in the pilular form, that it is convenient both for the physician and for the apothecary to have a formula indicating the mode of preparing the pills, as well as the quantity of rhubarb to be contained in each. Soap has stood the test of long experience as a good excipient for rhubarb. If made in quantity the pills should be kept in loosely stoppered bottles. We have found rhubarb pills made with compound tincture of cardamom, without other ingredient, to answer an excellent purpose. Each pill contains three grains (0.20 Gm.) of rhubarb.

PILULA SAPONIS COMPOSITA. Br.**COMPOUND PILL OF SOAP**

(pīl'ù-là sà-pō'nīs còm-pōs'ì-tà)

Pilules de Savon composées, *Fr.*; Seifenpillenmasse, *G.*

"Opium, in powder, $\frac{1}{2}$ ounce (Imperial) or 10 grammes; Hard Soap, in powder, $1\frac{1}{2}$ ounces (Imp.) or 30 grammes; Syrup of Glucose, $\frac{1}{2}$ ounce (Imp.) or 10 grammes. Mix to form a mass. This Pill contains 20 per cent. of Opium." *Br.*

This pill,¹ although no longer official in the U. S. P., is useful as affording the opportunity of conveniently administering opium, in a pilular and readily soluble form, in small fractions of a grain. The name was probably intended to conceal the nature of the preparation. One grain (0.065 Gm.) of opium is contained in about one dose, five grains (0.32 Gm.), of the mass.

PILULA SCAMMONII COMPOSITA. Br.**COMPOUND SCAMMONY PILL**

(pīl'ù-là sà-m-mō'nī còm-pōs'ì-tà)

Pilules de Scammonée composées, *Fr.*; Scammoniumpillenmasse, *G.*

"Scammony Resin, 1 ounce (Imperial) or 25 grammes; Jalap Resin, 1 ounce (Imp.) or 25 grammes; Curd Soap, in powder, 1 ounce (Imp.) or 25 grammes; Tincture of Ginger, 3 fl. ounces (Imp. meas.) or 75 cubic centimetres. Add the Tincture of Ginger to the Soap and Resins; dissolve with the aid of slight heat; evaporate on a water-bath until the mass has acquired a suitable consistence for forming pills." *Br.*

These pills are actively purgative in doses of from five to ten grains (0.32 to 0.65 Gm.).

PILULA SCILLÆ COMPOSITA. Br.**COMPOUND SQUILL PILL**

(pīl'ù-là scīl'la còm-pōs'ì-tà)

Pilules de Scille composées, *Fr.*; Meerzwiebelpillenmasse, *G.*

"Squill, in powder, $1\frac{1}{2}$ ounces (Imperial) or 25 grammes; Ginger, in powder, 1 ounce (Imp.) or 20 grammes; Ammoniacum, in powder, 1 ounce (Imp.) or 20 grammes; Hard Soap, in powder, 1 ounce (Imp.) or 20 grammes; Syrup of Glucose, 1 ounce (Imp.) or 20 grammes or a sufficient quantity. Mix to form a mass." *Br.*

This preparation was dropped at the 1880 revision of the U. S. Pharmacopœia.²

This is a stimulating expectorant compound, depending for its virtues chiefly on the squill, and applicable to the treatment of *chronic bronchitis*. From five to ten grains (0.32 to 0.65 Gm.) may be given three or four times a day. The mass should be freshly made when wanted, as the squill which it contains is liable to be injured by keeping.

PIMENTA. U. S., Br.**PIMENTA [Allspice, Pimento]**

(pī-mēn'tà)

"The dried, nearly ripe fruit of *Pimenta officinalis* Lindley (Fam. *Myrtaceæ*)." *U. S.*
"The dried full-grown unripe fruit of *Pimenta officinalis*, *Lindl.*" *Br.*

Semen Amomi, Piper Jamaicense; Pimento, Allspice, Jamaica Pepper; Piment de la Jamaïque, Tout-épice, Poivre de la Jamaïque, *Fr.*; Englisches Gewürz, Neugewürz, Nelkenpfeffer, *G.*; Piment, *It.*; Pimienta de la Jamaica, *Sp.*

Pimenta officinalis, *Lindl. B. & T.* 111; *Myrtus Pimenta*, *Willd., Sp. Plant.* ii. 973; *Eugenia Pimenta*, *De Cand. Prodom.* iii. 285; *Pimenta officinalis*, *Berg.* in *Engler and Prantl.*

This is a beautiful tree, about thirty feet high, with a straight trunk, much branched above, and covered with a very smooth gray bark. Its dense and ever-verdant foliage gives it at all times a refreshing appearance. The leaves, which are petiolate, vary in shape and size, but are usually about four inches long, elliptical, entire, blunt or obtusely pointed, veined, and of a deep shining green color. The flowers are small, without show, and disposed in panicles upon trichotomous stalks, which usually terminate the branches. The fruit is a spherical berry, crowned with the persistent calyx, and when ripe is smooth, shining, and of a black or dark purple color. The tree exhales an aromatic fragrance, especially during the summer months, when in flower.

It is a native of the West Indies, Mexico, and South America, and is abundant in Jamaica, whence its fruit received the name of *Jamaica pepper*. The allspice plant is cultivated in Central America and the surrounding countries, but more than half the supply to the United States comes from Jamaica, where the tree is so abundant as to form in the mountainous districts whole forests, and to require no further cultivation than the clearing out of the underbrush. The berries are gathered after having attained their full size, but while yet green, and are carefully dried in the sun. When sufficiently dry, they are put into bags and casks for exportation. The fruits of four other species of the genus *Pimenta*, found in Venezuela, Guiana, and the West Indies, are employed in their native countries as spices.

¹ *Pilula Saponis Composita*, U. S. P. 1870.—"Take of Opium, in fine powder, sixty grains; Soap, in fine powder, half a troyounce. Beat them together with water so as to form a pilular mass."

² *Pilula Scillæ Composita*, U. S. 1870. *Compound Pills of Squill*.—"Take of Squill, in fine powder, twelve grains; Ginger, in fine powder, Ammoniac, in

fine powder, each, twenty-four grains; Soap, in fine powder, thirty-six grains; Syrup, a sufficient quantity. Mix the powders together; then beat them with Syrup so as to form a pilular mass, to be divided into twenty-four pills." U. S. 1870.

Properties.—The berries, as they reach us, are of different sizes, usually about as large as a small pea, 5 to 7 Mm. in diameter, round, wrinkled, crowned with the short, four-parted calyx or its remnants and a short style, brownish or brownish gray, and when broken present two cells, each containing a black hemispherical or reniform seed. They have a fragrant odor, thought to resemble that of a mixture of cinnamon, cloves, and nutmeg. Hence the name of *allspice*, by which they are best known in this country. Their taste is warm, aromatic, pungent, and slightly astringent. They impart their flavor to water, and all their virtues to alcohol. The infusion is of a brown color, and reddens litmus paper. They are officially described as follows: "Subglobular, 5 to 7 Mm. in diameter, crowned with a short, 4-parted calyx and a short style, or their remnants; externally dark brown; pericarp brittle, about 1 Mm. thick, glandular-punctate; 2-celled, each cell containing one reddish-brown, plano-convex, slightly reniform seed; odor and taste peculiarly and agreeably aromatic." *U. S.* They yield a volatile oil by distillation having the sp. gr. of from 1.04 to 1.05 at 15° C. (See *Oleum Pimentæ*.) Bonastre obtained from them a volatile oil, a green fixed oil, a fatty substance in yellowish flakes, tannin, gum, resin, uncrystallizable sugar, coloring matter, malic and gallic acids, saline matters, moisture, and lignin. The green oil has the burning aromatic taste of pimenta, and is supposed to be the acrid principle. Upon this, therefore, together with the volatile oil, the medicinal properties of the berries depend, and, as these two principles exist most largely in the shell or cortical portion, this part is most efficient. According to Bonastre, the shell contains 10 per cent. of the volatile and 8 of the fixed oil, the seeds only 5 per cent. of the former and 2.5 of the latter. Berzelius considered the green fixed oil of Bonastre as a mixture of volatile oil, resin, fixed oil, and perhaps a little chlorophyll. Dragendorff in 1871 announced the existence of an alkaloid in allspice. It is present in exceedingly small quantity, and has somewhat the odor of coniine. W. W. Abell obtained from 448 Gm. of pimenta leaves one-half of one per cent. of volatile oil resembling oil of bay; he also found tannic acid. (*A. J. P.*, 1886, 163.) A convention of hygienists at Vienna decided that ground allspice should not yield more than 6 per cent. of ash, of which not more than 0.5 per cent. should be soluble in hydrochloric acid.

Pimenta is sometimes adulterated by the larger and less aromatic berries of the Mexican *Myrtus Tobasco*, Mocino.

Uses.—Pimenta is an aromatic spice, used in medicine chiefly as an adjuvant to tonics and purgatives. It is particularly useful in cases attended with much flatulence. It is, however, much more largely employed as a condiment than as a medicine.

Dose, ten to forty grains (0.65 to 2.6 Gm.).

Off. Prep.—Aqua Pimentæ, *Br.*

PIPER. U. S. (*Br.*)

PEPPER [Black Pepper]

(pī'per)

"The dried, unripe fruit of *Piper nigrum* Linné (Fam. *Piperaceæ*)." *U. S.* "The dried unripe fruit of *Piper nigrum*, Linn." *Br.*

Piper Nigrum, *Br.*; Common Pepper; Poivre noir, *Fr. Cod.*; Poivre, *Fr.*; Schwarzer Pfeffer, *G.*; Pepe nero, *It.*; Piment negro, *Sp.*; Fīdīl uswud, *Arab.*; Lada, *Malay*; Maricha, *Jav.*; Sahan, *Palembang*.

Piper nigrum, *L.*, *Sp. Pl.* (1753) 28; Willd., *Sp. Plant.* i. 159; Carson, *Illustr. of Med. Bot.*, ii. 38, pl. 83; *B. & T.* 245.—The pepper vine is a perennial plant, with a round, smooth, woody, articulated stem, swelling near the joints, branched, and from eight to twelve feet or more in length. The leaves are entire, broad-ovate, acuminate, seven-nerved, coriaceous, very smooth, of a dark green color, and attached by strong sheath-like footstalks to the joints of the branches. The flowers are small, whitish, sessile, covering thickly a cylindrical spadix, and succeeded by globular berries, which are red when ripe.

The plant grows wild in Cochin-China and various parts of India. It is cultivated on the coast of Malabar, in the peninsula of Malacca, in Siam, Sumatra, Java, Borneo, the Philippines, Japan, and many other places in the East; also to some extent in the West Indies. The best pepper is affirmed to be produced in Malabar, but Europe and America derive their chief supplies from Sumatra and Java. The plant is propagated by cuttings, and is supported by props, or trees planted for the purpose, upon which it is trained. In three or four years from the period of planting, it begins to bear fruit. The plant sometimes begins to bear as early as the first year after planting, increases in its yield to the fifth or sixth year, when it produces eight or ten pounds, and begins to lose its productiveness about the fifteenth year. The berries are gathered as soon as one is seen to turn red,—i.e., before they are all perfectly ripe,—and upon being dried, become black and wrinkled. The greatest production is in Sumatra, and the ports of export are principally Singapore and Penang, the Malabar pepper coming from Tellicherry. Our imports are principally through England, and not direct, and it seems that in England, at least, it is customary to mix peppers of different origin in grinding, taking Malabar for weight, Penang for strength, and Sumatra for color. (*Bulletin U. S. Dept. of Agric.*, No. 13, 1887.) The importations of unground black and white pepper for the year 1902 were 16,046,179 lbs.; for 1903, 21,832,675 lbs.; for 1904, 18,615,186 lbs. Owing to the widespread cultivation of pepper a large number of varieties exist; these receive their names from the place of their production. For a description of the most important of these varieties with the percentage of active constituents

contained in each, see J. W. Gladhill, *A. J. P.*, Feb. 1904; also Blyth, *Foods: their Composition and Analysis*.

White pepper is the ripe berry, deprived of a part of its pericarp by maceration in water and subsequent friction, and afterwards dried in the sun. It occurs as yellowish more or less broken grains with a smooth shiny surface, consisting of the perisperm alone, the epispem having been removed. It is sold in the market either as a whole white pepper or as broken white pepper; the whole peppers are very likely to have some of the perisperm or hull remaining. The removed hull is sold separately; it forms a light to dark brown powder, with a very pungent odor and taste and contains large amounts of the oleoresin of pepper, but according to Gladhill no piperine. The hulls are sometimes sold mixed with broken white pepper. This mixture contains more oleoresin and less piperine than does the pure pepper; the percentage of the two active constituents varying according to the percentage of drugs in the mixture. White pepper is much less pungent but more aromatic than black pepper.

Piper longum, L. (*Chavica longum*, Miq.), differs from its congeners in having its lower leaves cordate, petiolate, from five- to seven-nerved, its upper oblong-cordate, sessile, and five-nerved; its flowers in dense, short, terminal, and nearly cylindrical spikes and its fruit, consisting of very small one-seeded berries or grains, embedded in a pulpy matter. It is a native of Southeastern Asia, and is produced abundantly in Bengal and other parts of Hindostan. The fruit is green when immature, and becomes red as it ripens. It is gathered in the former state, as it is then hotter than when perfectly ripe. The whole spike is taken from the plant, and dried in the sun. *Long pepper*, as the fruit is called, is cylindrical, an inch or more in length, indented on its surface, of a dark-gray color, a weak aromatic odor, and a pungent fiery taste. Dulong found its chemical composition to be closely analogous to that of black pepper. Like that, it contains *piperine*, a concrete oil or soft resin upon which its burning acrimony depends, and a volatile oil to which it probably owes its odor. Its medicinal virtues are essentially the same as those of black pepper, but it is inferior to that spice, and is seldom used. *West African or Ashantee Pepper* is the fruit of *P. Clusii*, C. DC., which grows abundantly in tropical Africa. It does not come into Western commerce, although much used in Africa. The berry is described as resembling cubeb, but less rugose, and with a more slender pedicel, and having the odor and taste of black pepper. Stenhouse found piperine in this variety of pepper.

Kissi Pepper is a fruit yielded by the *Piper Famechonii*, Heckel, of Upper Guinea. The berries, which grow in cylindrical clusters, are small, blackish-brown, ovoidal, with a cubeb-like pedicel at their base. Their powder is very aromatic, with an especially pleasant taste. They

have been found by A. Barille to contain 4.5 per cent. of volatile oil and 3.7 per cent. of piperine. (*J. P. C.*, 106, 1903.)

Properties.—The dried berries are 4 to 5 Mm. in diameter, externally blackish, reticulated, and wrinkled, internally whitish, hollow, and with an undeveloped embryo, of an aromatic odor, and a hot, pungent, almost fiery taste. They are officially described as “nearly globular, 4 to 5 Mm. in diameter, externally brownish or grayish-black; pericarp thin, coarsely wrinkled, enclosing a single whitish, more or less imperfectly developed seed; odor strong, penetrating, provoking sneezing; taste aromatic and very pungent. The starch grains present in the powder are nearly spherical and about 0.002 Mm. in diameter; ash not more than 7 percent.” *U. S.* They yield their virtues partially to water, entirely to alcohol and ether. Pelletier found them to contain a peculiar principle called *piperine*, an acrid concrete oil or soft resin of a green color, a balsamic volatile oil, isomeric with oil of turpentine, a colored gummy substance, an extractive matter, like that found in leguminous plants capable of being precipitated by infusion of galls, starch, a portion of bassorin, tartaric and malic acids, lignin, and various salts. (See *Piperina*.) William Johnston (König's *Nahrungs- und Genussmittel*, 3d ed., Bd. i. 1046) finds that *piperidine*,¹ C₈H₁₁N, is an invariable constituent of pepper in amounts varying from 0.21 to 0.77 per cent. (See p. 965.)

The taste and medicinal activity of pepper depend mainly on the concrete oil or resin, and on the volatile oil. The concrete oil is of a deep green color, very acrid, and soluble in alcohol and ether. The volatile oil is limpid, colorless, becoming yellow by age, of a strong odor, and of a taste less acrid than that of pepper itself. Its formula is C₁₀H₁₆, and it forms a liquid but not a solid compound with hydrochloric acid. According to Weigle (*Ap. Ztg.*, 1893, 626), pepper contains, besides cellulose, starch, and coloring matter,—1. Volatile oil, smelling strongly of pepper, but without pungency; 2. A thick oil, tasteless and nearly odorless; 3. Odorless piperine whose solutions possess the pungency of pepper. Weigle believes that in the fresh fruit the volatile oil acts as a solvent for the piperine and he thus accounts for their pungency.

¹ According to the experiments of E. W. Tunnicliffe (*Ch. Phys.*, 1897), the injection of from 0.01 to 0.02 Gm. of the piperidine chloride will produce in a cat of about three kilograms' weight an enormous rise of the arterial pressure, due to narrowing of the blood paths. This is in accord with the investigations of B. Moore and E. Row (*Journ. Physiol.*, London, 1898), who find that piperidine produces paralysis of the intra-muscular part of the motor nerve, and, while slowing the heart, increases enormously the arterial pressure chiefly by causing a constriction of the arterioles by an action upon the peripheral ganglia. In this, as in other ways, resembling in its physiological effects conine and nicotine. The authors believe that this similarity is due to the presence of a reduced pyridine ring in each molecule, and, further, that the intensification of the action is caused by the introduction of an organic radical as a side group into this ring.

The following are analyses of commercial peppers made by Blyth (*Foods: their Composition and Analysis*, 5th ed., 1903, p. 496).

For a paper on commercial peppers by J. W. Gladhill see *A. J. P.*, 1904, 71.

Adulterations.—On account of its extensive use as a condiment, pepper has been largely adulterated, especially when sold in the form of a powder. Grapestones, olivestones, cocoanut shells and various other substances have been freely used as a mixture with the true black pepper. They can be detected by the microscope with more or less ease. See *P. J.*, lxxi. 269; *P. J.*, June, 1890; *Bull. U. S. Dept. of Agriculture*, No. 13, Part II, pp. 183, 1887; *A. J. P.*, 1887, 146; but when pepper has been adulterated to the amount of 10 per cent. the discovery of the fraud is best made by determining the proportion of ash, of ether extract and of piperine present. The ash should never be above 6.5 per cent. for black and 3 per cent. for white pepper; the ether extract should be between 7.5 and 10 per cent. for black and 6 to 9 per cent. for white pepper. Piperine should be present in from 5.5 to 9 per cent. in good black pepper. The amount of oleoresin in any pepper can readily be determined by subtracting the weight of piperine from that of the mixture. Penang pepper is sometimes made to resemble the higher priced white peppers by coating the grains with an earthy matter (lime or clay). According to A. Mennechet, the fruits of *Myrsine africana* and of *Embelia Ribes* may sometimes be detected in the powder of pepper by extracting with ether and adding a little water, followed by a few drops of ammonia, when after shaking, a deep lilac-red color will appear in the aqueous layer. (*J. P. C.*, xiv. 587.)

Uses.—Black pepper is a warm carminative stimulant, capable of producing general arterial excitement, but acting with greater proportional energy on the part to which it is applied. From the time of Hippocrates it has been used as a condiment and in medicine. Its chief medicinal application is to excite the languid stomach and correct flatulence. It was for years occasionally administered for the cure of *intermittents*, but its employment for this purpose had passed from the profession to the laity, till a few years since revived by an Italian physician, to be again consigned to forgetfulness. Piperine has also been employed in the same disease, and has even been thought

superior to quinine sulphate, but experience has not confirmed this favorable opinion. That, in its impure state, when mixed with a portion of the acrid principle, it will occasionally cure intermittents, there can be no doubt, but it is not comparable to the preparations of cinchona, and is certainly less active than the official oleoresin of pepper. In intermittent fever, pepper may be found a useful adjuvant to the more powerful febrifuge. It may be given whole or in powder, but is more energetic in the latter state.

Dose, of pepper, five to twenty grains (0.32 to 1.3 Gm.).

PIPERINA. U. S.

PIPERINE [Piperin, Piperinum, *Pharm.* 1890]

(pī-pē-rī'nā)

$C_{17}H_{19}NO_3 = 283.04$

"A feebly basic substance [$CH_2O_2.C_6H_3.CH:CH.CH:CH.CON.C_6H_{10}$] obtained from Pepper and other plants of the *Piperaceæ*." *U. S.*

Pipérine, *Fr.*; Piperin, *G.*

It will be observed that the official title of this principle has been changed in the *U. S. P.* (8th Rev.) to "Piperina," thus restoring it to the class of alkaloids. It has never been claimed by chemists that piperine had all the properties of the alkaloids as a class; it was described as a "principle of feebly alkaloidal power" in the *U. S. P.* 1880, and this view has been retained in the *U. S. P.* (8th Rev.).

Piperine was discovered by Ersted of Copenhagen, who considered it to be the active principle of pepper. Pelletier, however, denied its medicinal activity, and ascribed all the effects supposed to have been obtained from it to a portion of the acrid concrete oil with which it is mixed when not very carefully prepared. It is obtained by treating pepper with alcohol, evaporating the tincture to the consistence of an extract, submitting the extract to the action of an alkaline solution by which the oleaginous matter is converted into soap, washing the undissolved portion with cold water, separating the liquid by filtration, treating the matter left on the filter with alcohol, and allowing the solution thus obtained to evaporate spontaneously or by a gentle heat. Crystals of piperine are

deposited, and may be purified by alternate solution in alcohol or ether, and crystallization. Piperine may be regarded as a *piperidine*, $C_8H_{11}N$, in which one H is replaced by the radical of *piperic acid*, thus: $C_8H_{10}N.C_{12}H_9O_3$. Piperine does not yield salts with acids. (*Buchner's Neues Rep.*; *A. J. P.*, Oct. 1876.) Rügheimer (*A. J. P.*, Aug. 1882, 397) has regenerated piperine by the union of piperidine and the chloride of the radical of piperic acid, thus making piperine artificially. The properties of this artificial principle are identical with those of the natural piperine.¹

Piperidine is a powerful volatile alkaloid, soluble in all proportions in water and alcohol, and forming crystalline salts with acids. It is one of the decomposition products of piperine and is of great chemical interest as being a simple derivative of pyridine, C_5H_5N , which seems to underlie the molecular structure of so many alkaloids. Piperidine is *hexahydropyridine*, $C_6H_{11}N$, and can be easily obtained from pyridine by the action of tin and hydrochloric acid, or when sodium acts upon the alcoholic solution. Conversely, piperidine can be changed into pyridine when sulphuric acid at 300° C. or gentle oxidizing agents act upon it. Coniine, it will be remembered (see *Conium*), has been shown synthetically to be a normal propyl-piperidine.

Properties.—When perfectly pure, piperine is in colorless transparent crystals, without taste, with no perceptible action on litmus paper, and fusible at 128° to 129.5° C. (262.4° to 265° F.) (Rügheimer, *A. J. P.*, Aug. 1882, p. 397), capable of being sublimed under favorable circumstances in perfect crystals (Waddington, *P. J.*, March, 1868, p. 415), insoluble in cold water, slightly soluble in boiling water which deposits it upon cooling, soluble in alcohol, ether, and acetic acid, and still more readily in chloroform, benzene, and petroleum benzin, decomposed by the concentrated mineral acids, with sulphuric becoming of a blood-red color, with nitric first of a greenish-yellow, then orange, and ultimately red. As ordinarily procured, the crystals are yellow. Piperine is gen-

erally believed to be a weak alkaloid of the formula $C_{17}H_{19}NO_3$. When boiled with strong solution of potassium hydroxide or heated with soda-lime it is converted into *piperic (piperinic) acid*, $C_{12}H_{10}O_4$, and *piperidine*, $C_8H_{11}N$.

It is officially described as "colorless or pale yellowish, glistening, monoclinic crystals, odorless, permanent in the air, and containing no water of crystallization. When put into the mouth, it is at first tasteless, but on prolonged contact it develops a sharp, biting taste. It is optically inactive. Insoluble in water; soluble in 15 parts of alcohol, 36 parts of ether, and in 1.7 parts of chloroform at 25° C. (77° F.); soluble in 4.4 parts of alcohol at 60° C. (140° F.). It melts at 130° C. (266° F.). Upon ignition, it emits alkaline vapors, and is completely consumed. Its alcoholic solution is neutral to litmus paper. Sulphuric acid dissolves Piperine with the formation of a blood-red color, which disappears on dilution with water. On heating 1 Gm. of Piperine with alcoholic potassium hydroxide, it is converted into piperinic acid and piperidine, the latter recognizable by its alkaline, pepper-like odor, and the former by its melting point, 215° C. (419° F.). On adding a crystal of Piperine to sulphuric acid containing about half its volume of solution of formaldehyde, a permanently green liquid is formed. On adding a crystal of Piperine to sulphuric acid containing a fragment of potassium dichromate, it at once acquires a purple color, and, on stirring, dissolves, forming a reddish-brown solution, which becomes greenish on adding water to it. On adding a crystal of Piperine to sulphuric acid containing a trace of selenous acid, it turns brown, changing at once to violet, and dissolves, forming a brown solution changing to green. When heated with nitric acid, Piperine is colored at first orange, then red, and the acid acquires a yellow color, deepening to reddish as the crystals dissolve. On adding to this solution an excess of potassium hydroxide T.S., the color is at first yellow, but upon boiling, it becomes blood-red." *U. S.*

Uses.—(See *Piper*, p. 962.)

Dose, three to five grains (0.2 to 0.32 Gm.).

¹*Heliotropin*. (*Piperonal*).—This interesting substance, although used almost exclusively in perfumery, has been recommended by Fragaad (*Pix Gen-trath.*, xxviii. 253) as an antiseptic and antipyretic. It may be obtained by the oxidation of piperic acid, as follows. Piperine is made to yield potassium piperate by boiling it for twenty-four hours with an equal part of potassium hydroxide and 5 parts of alcohol. This is then dissolved in from 40 to 50 parts of hot water, and the hot solution slowly mixed, under constant stirring, with a solution of 2 parts (that is, twice the weight of the sodium piperate) of potassium permanganate. The resulting magma is put on a strainer and repeatedly washed with hot water, until it no longer has the characteristic odor of heliotropin. The united liquids are now distilled, and from the first portions of the distillate which are received separately, the larger portion of the heliotropin or rather piperonal ($C_8H_7O_3$) separates, on cooling, in crystals; the remainder may be obtained by shaking the distillate with ether. (*Chem. Ztg.*, 1884.) This piperonal is the aldehyde of piperonylic acid $C_8H_7(COOH)O > CH_2$, which, as the formula indicates, is the methylene ester of protocatechual acid, $C_8H_7COOH(OH)_2$. See also *Schim. Rep.*, 1903, 133.

PIX BURGUNDICA. Br.

BURGUNDY PITCH

(pix bur-gün'dj-çə)

"The resinous exudation obtained from the stem of *Picea excelsa*, *Link.*, melted and strained." *Br.*

Poix de Bourgogne, Poix des Vosges, Poix jaune, *Fr. Cod.*; Poix blanche, *Fr.*; Burgundisches Pech, Burgunder Harz, Wasserharz, *G.*; Pece di Borgogna, *It.*; Pez de Borgoña, *Sp.*

The Coniferae have been divided by Eichler, in Engler and Prantl's work, into the following suborders,—viz, *Pinoideæ*, or Conifers proper, and *Taxoideæ*. Eichler does not consider that these subdivisions are deserving of family dis-

tion, as indicated by Lindley and followed by Britton and Brown in their Flora. The genus *Pinus* of Linnæus has been divided into the following genera: *Pinus* (the Pines), *Larix* (the Larches), *Picea* (the Spruces), *Tsuga* (the Hemlocks), and *Abies* (the Firs).

Picea excelsa, Link.—*Abies excelsa*, De Candolle.—*Pinus abies*, Willd., *Sp. Plant.* iv. 506; Woodv., *Med. Bot.* p. 4, t. 2.—*Pinus Picea*, Du Roi. *B. & T.* 261.—The Norway spruce is a lofty tree, rising sometimes one hundred and fifty feet in height, with a trunk from three to five feet in diameter. The leaves, standing thickly upon the branches, are short, obscurely four-cornered, often curved, of a dusky green color, and shining on the upper surface. The male aments are purple and axillary, the female of the same color, but usually terminal. The fruit is in pendent, purple, nearly cylindrical strobiles, the scales of which are oval, pointed, and ragged at the edges.

This tree is a native of Europe and Northern Asia. Though designated as the source of Burgundy pitch, it furnishes but a part of the substance sold under that name. Tingley asserts that the real Burgundy pitch is obtained from the *Abies Picea*, or European silver fir tree. According to Geiger, who is probably correct, it is procured from both species. To obtain the pitch, portions of the bark are removed so as to lay bare the wood, or perpendicular grooved channels are cut, and the flakes of concrete resinous matter which form upon the surface of the wound, having been detached by iron instruments, are melted with water in large boilers, and then strained through coarse cloths. It is called Burgundy pitch from the province of that name in the east of France, although whether it was ever produced in that province is uncertain. It is chiefly collected in Finland, the Schwarzwald, Austria, and the Bernese Alps.

From various species of pine, in different parts of Europe, a similar product is obtained and sold by the same name. It is prepared by removing the juice which concretes upon the bark of the tree, or upon the surface of incisions, called *galipot* by the French, and purifying it by melting, and straining either through cloth or a layer of straw. A *factitious Burgundy pitch* is made by melting together common pitch, rosin, and turpentine, and agitating the mixture with water, which gives it the requisite yellow color. Its odor is different from that of the genuine. Hanbury gives as a test of true Burgundy pitch that it is almost entirely soluble in twice its weight of glacial acetic acid, while the factitious article similarly treated forms a turbid mixture, quickly separating into a thick oily liquid above, and a bright solution below.¹

As brought to this country, Burgundy pitch is generally mixed with impurities, which require that it should be melted and strained before being used. In its pure state according to the U. S. P. 1890 it is "hard, yet gradually taking the form of the vessel in which it is kept; brittle, with a shining, conchoidal fracture, opaque or translucent, reddish-brown or yellowish-brown, odor agreeably terebinthinate; taste aromatic, sweetish, not bitter. It is almost entirely soluble in glacial acetic acid, or in boiling alcohol, and partly soluble in cold alcohol." U. S. 1890. It is very fusible, and at the heat of the body softens and becomes adhesive. It differs from turpentine in containing a smaller proportion of volatile oil. Instead of the sylvic acid of ordinary rosin, it contains an isomeric acid, which has been called *pimaric acid*, melting at 148° to 149° C., difficultly soluble in cold but readily soluble in boiling alcohol, and also soluble in ether. According to Perrenoud, its formula is $C_{40}H_{54}O_4$, but Vesterberg (*Ber. d. Chem. Ges.*, 1885, p. 3331) showed it to be a mixture, and has since (*Ibid.*, 1886, p. 2167, and 1887, p. 3248) prepared from it two isomeric crystalline acids, a *dextropimaric acid* and a *levopimaric acid*, both of the formula $C_{20}H_{30}O_2$; with these is mixed a varying amount of an amorphous resin acid known as *pimic acid*.

Uses.—Applied to the skin, in the shape of a plaster, Burgundy pitch acts as a gentle rubefacient, producing a slight inflammation without separating the cuticle. Sometimes it excites a papillary or vesicular eruption, and we have known it to act as a violent irritant, giving rise to severe pain, swelling, and redness, followed by vesication and even ulceration. It is used chiefly in chronic *rheumatic pains*, and in chronic affections of the chest or abdomen, which call for a gentle but long-continued revulsion of the skin.

PREPARED COAL TAR

(pīx cār'bō-nīs præ-pa-rā'ta)

"Prepared by placing commercial coal tar in a shallow vessel, and maintaining it at a temperature of 120° F. (48.9° C.) for one hour, stirring frequently." Br.

Prepared coal tar was introduced into the Br. Pharm. 1898; it is the chief constituent in the preparation of *Liquor Picis Carbonis*. (See p. 728.) It has no other use in medicine.

Off. Prep.—Liquor Picis Carbonis, Br.

¹ The resinous exudation from *Pinus sylvestris* is sometimes offered as Burgundy pitch, but Hirschsohn (*Ph. Z. R.*, xxiv.) states that it is possible to distinguish the resin of *Picea excelsa* by its being only

partially soluble in ether, chloroform, and solutions of salts of ammonium, sodium carbonate, and borax, which dissolve completely the resin of *Pinus sylvestris*. The resin of *Picea excelsa* is also precipitated by the addition of water from its sulphuric acid solution in red violet flakes, while *Pinus sylvestris* resin precipitates white.

PIX LIQUIDA. U. S., Br.

TAR

(pix liq'u-də)

"A product obtained by the destructive distillation of the wood of *Pinus palustris* Miller, or of other species of *Pinus* (Fam. *Pinaceæ*)." U. S. "A bituminous liquid, obtained from the wood of *Pinus sylvestris*, Linn., and other species of *Pinus*, by destructive distillation. Known in commerce as Stockholm tar." Br.

Resina Empyreumatica Liquida; Goudron végétal, Fr. Cod.; Goudron, Fr.; Theer, G.; Pece liquida, It.; Brea de pino, Alquitran vegetal, Sp.

The tar used in this country is prepared from the wood of various species of pine, particularly *Pinus palustris* of the Southern States. (See *Terebinthina*.) The dead wood is usually selected, because, when vegetation ceases, the resinous matter becomes concentered in the interior layers. The wood is cut into billets of a convenient size, which are placed together so as to form a large stack or pile and then covered with earth as in the process for making charcoal. The stack is built upon a small circular mound of earth previously prepared, the summit of which gradually declines from the circumference to the centre, where a cavity is formed, communicating by a conduit with a shallow ditch surrounding the mound. Fire is applied through an opening in the top of the pile, and a slow combustion is maintained, so that the resinous matter may be melted by the heat. This runs into a cavity in the centre of the mound, and passes thence by the conduit into the ditch, whence it is transferred into barrels. Immense quantities of tar are thus prepared in North Carolina and the south-eastern parts of Virginia, sufficient, after supplying our own consumption, to afford a large surplus for exportation.¹ Considerable quantities of tar have been prepared also in the lower parts of New Jersey, in some portions of New England, and in Pennsylvania west of the Alleghany Mountains, from the *Pinus rigida*, or pitch pine, and perhaps from some other species.

Properties.—Tar has an acid reaction, a peculiar empyreumatic odor, a bitterish, resinous, somewhat acid taste, a color almost black, and a tenacious consistence intermediate between that of a liquid and that of a solid; by age it becomes granular and opaque. It consists of resinous matter, united with acetic acid, oil of turpentine, and various volatile empyreumatic products, and colored with charcoal. By distillation it yields an acid liquor called *pyroligneous acid* (see *Acidum Aceti-*

cum), and an empyreumatic oil called *oil of tar*; what is left behind is *pitch*. Officially it is described as "semi-liquid, viscid, blackish-brown, non-crystalline, translucent in thin layers, becoming granular and opaque with age; odor empyreumatic, terebinthinate; taste sharp and empyreumatic. Tar is soluble in alcohol, fixed or volatile oils, or solutions of potassium or sodium hydroxide; it is heavier than water and is slightly soluble in it, the solution being of a pale yellowish-brown color and having an acid reaction." U. S. It is described in the Br. Pharm. as "a dark-brown or blackish semi-liquid substance, of a peculiar aromatic odor. The specific gravity varies from 1.02 to 1.15. Water agitated with it acquires a pale-brown color, sharp empyreumatic taste, and acid reaction, and with dilute test-solution of ferric chloride assumes a red color. Tar is completely soluble in ten times its volume of alcohol (90 per cent.)." Br.

The first examination of the empyreumatic oil was made by Reichenbach of Moravia, who found a variety of substances, to which he gave the names of *paraffin*, *eupion*, *creosote*, *picamar*, *capnomor*, and *pittacal*. It has been found by more careful study of wood tar that it contains a great variety of compounds, including the hydrocarbons *toluene*, C_7H_8 , *xylylene*, C_8H_{10} , *mesitylene* and *pseudocumene*, C_9H_{12} ; phenols like common *phenol*, C_6H_5O , *creosol*, C_7H_5O , *guaiacol*, $C_7H_5O_2$, *creosol*, $C_8H_{10}O_2$, *phlorol*, $C_8H_{10}O$, and *methylcreosol*, $C_8H_{12}O_2$, the last four constituting the mixture known as *creosote*; and, lastly, *paraffin* in variable quantity, depending upon the temperature of distillation, *naphthalene*, $C_{10}H_8$, *pyrene*, $C_{16}H_{10}$, *chrysene*, $C_{18}H_{12}$, and *retene*, $C_{19}H_{12}$. *Pyrocatechol*, $C_6H_4(OH)_2$, is also obtained, either in the pyroligneous acid, as it is soluble in water, or in the tarry mixture. It crystallizes readily, fuses at $104^\circ C.$ ($219.2^\circ F.$), and sublimes at a temperature slightly above this. Tar yields a small proportion of its constituents to water, which is thus rendered medicinal, and is employed under the name of *tar water*. Tar water is of "a pale yellowish-brown color and an acid reaction, yields with ferric chloride test-solution a transient green color, and is colored brownish-red by an equal volume of calcium hydrate test-solution." Tar is dissolved by alcohol, ether, chloroform, and the volatile and fixed oils, and by a solution of potassium or sodium hydroxides. On spreading tar in a thin layer on a pane of glass it should present a homogeneous appearance. Those specimens which contain granular transparent masses should be rejected. These masses, which polarize brilliantly, are said to be *pyrocatechol*. Tar should have a specific gravity of 1.03 to 1.07; it should boil at from 250° to $400^\circ C.$ Its reaction should be acid. "*Steam refined tar*" is tar which has been simply heated in steam caldrons and strained to remove foreign impurities.

Hirschsohn has suggested the following plan for the identification of different varieties of

¹According to R. J. Dunwoody (A. J. P., 1889), tar is also prepared on a small scale by wedging vertically into an iron pot the pieces of split wood, inverting over the projecting ends another iron pot, and setting fire to the wood; or by simply placing the billets of wood on the top of an inclined plane of sheet iron, setting the wood on fire, and catching the tar which runs down.

tar. 1. *Completely soluble in 95 per cent. acetic acid. Pine Tar.*—French turpentine dissolves it completely. The petroleum ether extract of the tar is colored greenish when shaken with a dilute solution of cupric acetate (1 : 1000). Chloroform and absolute ether dissolve it completely. *Beech Tar.*—Turpentine oil dissolves it only partially. The petroleum ether extract is not colored by copper acetate solution. Chloroform and absolute ether do not entirely dissolve it. 2. *Not completely soluble in 95 per cent. acetic acid. Juniper Tar.*—Turpentine oil dissolves it completely. Aniline dissolves it completely. The aqueous extract (1 : 20) yields a red coloration with dilute solution of ferric chloride (1 : 1000). *Birch Tar.*—Turpentine oil dissolves it completely. Aniline does not dissolve it completely. The aqueous extract is colored greenish by ferric chloride. Turpentine oil dissolves it only partially. *Aspen Tar.*—Benzene, chloroform, absolute ether, and olive oil dissolve it only partially. (*Ph. Ztg.*, 97, 396; *Ph. Z. R.*, 97.)

The pitch left after the evaporation of tar was formerly official with the British Colleges, under the names of *Pix nigra*, *Pix arida*, or simply *Pix*. It has a shining fracture, softens and becomes adhesive with a moderate heat, melts in boiling water, and consists of the unaltered resin of the pine and of various empyreumatic resinous products which have received the name of *pyretin*. (Berzelius, *Traité de Chimie*, vi. 641, 680.) It has been used internally in *ichthyosis* and other cutaneous diseases, and in *piles*. The dose is from ten grains to a drachm (0.65 to 3.9 Gm.), given in pill. Pitch is also used externally in the form of ointment.

Uses.—The medicinal properties of tar are similar to those of the turpentines, but it is much less irritant. It is occasionally used with advantage in *chronic catarrhal affections*, and in *diseases of the urinary passages*. Little benefit can be expected from it in genuine *phthisis*, in the treatment of which it was formerly recommended. In reference to the administration of tar, it has always been considered desirable to have it in a soluble state, so that it might be brought with facility into a liquid form if required. Besides, tar in the stomach will probably be found efficacious in proportion to its solubility. This desired end was attained when it was discovered that tar was capable of forming a definite, solid compound with sugar which was very soluble in water. Saccharated tar contains 4 per cent. of pure tar, resembles sugar in appearance, having a sweet taste and the odor of tar, and may be given in substance or solution as deemed desirable. (*P. J.*, Sept. 1871.) (See *Syrupus Picis Liquidæ*.)¹ But glycerin is a more con-

venient vehicle, and glycerite of tar was an official preparation in 1870. Its vapor, inhaled into the lungs, may be serviceable in *chronic bronchitis* and *phthisis*. Its effects are most conveniently obtained by placing tar or oil of tar in a tin dish containing hot water, and heating this; the fumes may be inhaled by inverting a funnel to which a rubber tube is attached, over the dish. Externally applied it is a decided stimulant, and in the state of ointment is a very efficient remedy in *tinea capitis* or *scaldhead*, and in some cases of *psoriasis*, in *chronic eczema*, and other *affections of the skin*.²

It may be used in the form of tar water (see *Infusum Picis Liquidæ*), or in substance made into pills with wheat flour, or mixed with sugar in the form of an electuary. Tar may be administered to the amount of one to two fluidrachms (3.75 to 7.5 Cc.) daily.

Pulverulent tar is prepared by Magnes-Lahens, by mixing, in an earthenware vessel, two parts of finely divided charcoal and one part of liquid tar. The resulting mixture resembles small grains of gunpowder, does not soil the vessel or the fingers, and yields readily to water the tar which it contains,—the most favorable temperature for solution being about 20° C. (68° F.). Magnes-Lahens recommends a syrup prepared from the powder as follows. Take of pulverulent tar 50 Gm., water 180 Gm., granulated sugar 320 Gm. Mix the tar and sugar in a mortar, then add the water, and heat the mixture by a water bath at 60° C. (140° F.). Then remove from the bath, shake until the sugar is all dissolved, and strain when hot, and afterwards again when cold. A tablespoonful of the syrup, added to a tumbler of water, yields a tar water resembling that of the French Codex. The pulverulent tar may also be used for pills, and also for fumigating purposes by throwing a few grains on a heated shovel. (*P. J.*, April, 1872, 850.)

Dose, five to twenty grains (0.32 to 1.3 Gm.).

Off. Prep.—*Syrupus Picis Liquidæ*, *U. S.*; *Unguentum Picis Liquidæ*, *U. S.*, *Br.*

6 pints. Mix the glycerin, sherry wine, honey, acetic acid, and boiling water together, in a stone jug or other suitable vessel of the capacity of a gallon. To the mixture add the tar, and shake the whole vigorously for several minutes. The vessel is then to be tightly stopped and placed upon a stove or in a water bath, resting upon folds of paper, and the mixture digested, for an hour or two, at a temperature of from 150° to 160° F. During the digestion the mixture should be frequently well shaken. When the digestion is completed, the mixture is to be set aside to macerate, in a warm place, for a few days, it being well shaken occasionally during the process. Lastly, strain through muslin, and filter the strained liquid through paper.

¹*Liquor Picis Alkathinus*.—L. D. Bulkeley of New York, gives the following formula for this preparation, which was originally devised by his father. Tar, 120 grains; Caustic Potash, 60 grains; Water, five fluidrachms. Mix and dissolve for external use. This mixes with water in all proportions, and only moderately discolors the skin. It dries rapidly and leaves very little stickiness. (*Medical News and Library*, June, 1873.)

¹ *Wine of Tar* (J. B. Moore).—Pure Tar, 16 troy-ounces; Glycerin, Sherry Wine, Honey, of each, 8 fluidounces; Acetic Acid, 1 fluidounce; Boiling Water,

PLUMBI ACETAS. U. S., Br.

LEAD ACETATE [Sugar of Lead]

(plūm'bi a-cē'tas)

"It should contain not less than 99.5 per cent. of pure Lead Acetate $[(\text{CH}_3\text{COO})_2\text{Pb} + 3\text{H}_2\text{O}]$, and should be kept in well-stoppered bottles." *U. S.* "A salt, $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2, 3\text{H}_2\text{O}$, obtained by dissolving lead oxide or lead carbonate in acetic acid." *Br.*

Acetas Plumbicus, Saccharum Saturni, Cerussa Acetata; Acétate neutre de Plomb, Sucre de Plomb, Sel de Saturne, *Fr. Cod.*; Plumbi Aceticum, *P. G.*; Bleiacetat, Essigsäures Bleioxyd, Bleizucker, *G.*; Acetato neutro di piombo, Zucchero di Saturno, *It.*; Acetato plumbico neutro, Azúcar de Saturno, *Sp.*

Preparation.—Lead acetate is obtained by two methods. By one method, thin plates of lead are placed in shallow vessels filled with distilled vinegar, in such a manner as to have a part of each plate rising above the vinegar, and these are turned from time to time, so as to bring different portions of the metallic surface in contact with the air. The metal, in the presence of the oxygen of the air, dissolves in the vinegar to saturation, and the solution is evaporated to the point of crystallization. This process is a slow one, but furnishes a salt which is perfectly neutral. The other method consists in dissolving, by the assistance of heat, litharge, or lead protoxide obtained by calcination, in an excess of distilled vinegar or of purified pyroligneous acid, contained in leaden boilers. The oxide is quickly dissolved, and, when the acid has become saturated, the solution is transferred to other vessels to cool and crystallize. The crystals having formed, the mother waters are decanted, and, by evaporation, made to yield a new crop. These are generally yellow, but may be rendered white by repeated solutions and crystallizations.

Lead acetate is extensively manufactured in Germany, Holland, France, and England, as well as in the United States. It is principally consumed in the arts of dyeing and calico printing, in which it is employed with alum, to form aluminum acetate, which acts as a mordant.

Properties.—"Colorless, shining, transparent, monoclinic prisms or plates, or heavy, white, crystalline masses, or granular crystals, having a faintly acetous odor, and a sweetish, astringent, afterwards metallic taste. Efflorescent, and absorbing carbon dioxide, on exposure to the air. Soluble in 2 parts of water, and in 30 parts of alcohol at 25° C. (77° F.); in 0.5 part of boiling water, and in 1 part of boiling alcohol. When heated to 40° C. (104° F.), the salt loses its water of crystallization (14.26 per cent.). When heated rapidly to 75° C. (167° F.) it fuses in its water of crystallization, and at a higher temperature is converted into a pulverulent basic salt which fuses

at about 280° C. (536° F.) with continued loss of acetic acid, finally decomposing with the evolution of carbon dioxide and acetone, leaving a residue of finely divided metallic lead mixed with oxide and carbonate. On heating the salt with sulphuric acid, vapors of acetic acid are evolved. The aqueous solution of Lead Acetate has a neutral or slightly alkaline reaction, and yields a black precipitate with hydrogen sulphide T.S., a yellow one with potassium iodide T.S., and a white one with diluted sulphuric acid. A solution of the salt (1 in 10), prepared with water which has been recently boiled, should be clear, or only slightly opalescent (limit of carbonate), and should yield, with potassium ferrocyanide T.S., a pure white precipitate (absence of iron and copper). If to the aqueous solution of the salt (1 in 10), hydrochloric acid be added until no further precipitate is produced, the remainder of the lead removed from the filtrate by hydrogen sulphide, and the liquid filtered, a portion of the second filtrate should not be affected by the addition of a slight excess of ammonia water (absence of zinc and iron). If another portion of the filtrate be evaporated to dryness, it should leave no residue (absence of salts of the alkali metals, and those of magnesium, calcium, zinc, and iron)." *U. S.* "It is soluble in less than 3 parts of cold water, and in 30 parts of alcohol (90 per cent.). Its solution in water slightly reddens litmus, and is clear, or has only a slight milkiness, which disappears on the addition of acetic acid. It affords the reactions characteristic of lead and of acetates. It should yield no characteristic reaction with the tests for silver, copper, arsenium, iron, zinc, calcium, sodium, potassium, ammonium, chlorides, or nitrates. Each gramme dissolved in water should require for complete precipitation 53.1 cubic centimetres of the decinormal volumetric solution of sulphuric acid." *Br.* Exposed to the air, it effloresces slowly. In pure distilled water, free from carbon dioxide, it ought to dissolve entirely and form a clear solution. The commercial acetate is sometimes impure from the presence of lead sulphate and carbonate. In purchasing it the apothecary should select large crystalline masses. John Mackay analyzed a specimen of this salt, derived from the London market, which contained nearly 30 per cent. of lead sulphate. (*P. J.*, Jan. 1856, 316.) Sulphuric acid, when added to a solution of lead acetate, produces instantly a precipitate of lead sulphate, and the disengaged acetic acid gives rise to vapors having the odor of vinegar. An important property of lead acetate is its power of dissolving a large quantity of lead monoxide. (See *Liquor Plumbi Subacetatis*.)¹ It consists of one atom

¹ *Lead Subacetate (Crystallized).*—James Kennedy recommends this salt for preparing the cerate, as follows: Dissolve 4 parts of Lead Acetate in 4 parts of Boiling Distilled Water, add 3 parts of Litharge, boil for fifteen or twenty minutes, stirring, and occasionally adding water to replace that evaporated, allow to stand a few minutes, decant and filter the solution; concentrate by evaporation and allow to crystallize. By dissolving 25 parts of this salt in

of lead, which has replaced the two hydrogen atoms furnished by two molecules of acetic acid, $C_2H_3O_2.H$, so that its formula becomes $Pb(C_2H_3O_2)_2$, and this in crystallizing takes $3H_2O$. Its molecular weight is therefore 376.15.

Incompatibles and Tests.—Lead acetate is decomposed by all acids, and by those soluble salts the acids of which produce with lead monoxide insoluble or sparingly soluble compounds. Acids of this character are sulphuric, hydrochloric, phosphoric, tannic, citric, and tartaric. It is also decomposed by lime water, and by ammonia, potassium and sodium hydroxides; the last two, if added in excess, dissolving the precipitate at first formed. It is decomposed by hard water, in consequence of the calcium sulphate, carbonates and sodium chloride which such water usually contains.

Uses.—Lead acetate, in medicinal doses, is a powerful astringent and sedative; in overdoses, an irritant poison, which has in a number of cases caused death. Burning epigastric pain, vomiting of a white curdy matter (lead chloride), and diarrhoea or constipation with black stools (lead sulphide), and finally collapse, are the characteristic symptoms. Its antidote is any soluble sulphate, common salt, soap, or an alkali. In medicinal doses lead acetate is a powerful sedative astringent. It is especially useful in the treatment of *diarrhoeas*, and even of *dysentery*, when the discharges are excessive. At one time it was very much used for the relief of *internal hemorrhages*, but it has been substituted by more effective remedies. It may be, however, effective in *gastric or intestinal hemorrhages*. In many cases of *chronic diarrhoea* or in *diarrhoeas* occurring in exhaustive, uncontrollable disease, such as *phthisis*, lead acetate, combined with opium, may be a valuable palliative in checking discharges. It has been given also in *aneurism* of the aorta. The prolonged medicinal use of acetate of lead may give rise to subacute or chronic lead poisoning.

Internally, lead acetate should always be given in the form of pill, and is often combined with opium. The solution for external use may be made by dissolving from two to three drachms in a pint of water, and, if it be wanted clear, a fluidrachm of vinegar or of diluted acetic acid may be added, which immediately dissolves the lead carbonate, to which its turbidity is owing. When the skin is denuded of the cuticle, the solution should be weaker. The usual strength of the solution as a collyrium is from one to two grains (0.065 to 0.13 Gm.) to the fluidounce (30 Ce.) of *distilled water*.

Dose, one to three grains (0.065 to 0.20 Gm.).

PLUMBI CARBONAS. Br.

LEAD CARBONATE [White Lead]

(plūm'bi cār'bq-nās)

$(PbCO_3)_2.Pb(OH)_2 = 768.91$

"Lead Carbonate or hydroxy-carbonate, $2PbCO_3.Pb(OH)_2$, may be prepared by the interaction of lead, water, and carbonic anhydride, in the presence of vapors of acetic acid." *Br.*

Plumbum Carbonicum, Carbonas Plumbicus, Ceruse; Carbonate de Plomb, Céruse, *Fr. Od.*; Blanc de Plomb, Blanc de Céruse, *Fr.*; Cerussa, *P. G.*; Bleiweiss, *G.*; Cerussa, *It.*; Albalayde o cerussa, *Sp.*

This compound of lead was dismissed from the *U. S. Pharmacopœia* (8th Rev.).

Preparation.—Lead carbonate is prepared by two principal methods. By one method it is obtained by passing a stream of carbon dioxide through a solution of lead subacetate. The dioxide combines with the lead hydroxide of the basic salt, and precipitates as lead carbonate, while a neutral acetate remains in solution. This, by being boiled with a fresh portion of oxide, is again brought to the state of basic salt, when it is treated with carbon dioxide as before. In this way the same portion of acetate repeatedly serves the purpose of being converted into subacetate and of being decomposed by carbon dioxide. The carbonate obtained is washed, dried with a gentle heat, and thrown into commerce. This process, which produces white lead of the first quality, was invented by Thénard, about the year 1802, and is that which is usually pursued in France and Sweden, and known as the "Clichy process." Benson's modification of the process of Thénard is now used by some manufacturers in England. It consists in mixing litharge with a hundredth part of lead acetate, moistening the mixture with very little water and subjecting it to a stream of carbon dioxide.

The other, called the "Dutch process" from its origin in Holland, consists in exposing lead to the vapor of vinegar, and is usually pursued in England and the United States,—but in England with some not well known modifications. We shall describe this process as employed by our own manufacturers. The lead is cast into thin sheets, made by pouring the melted lead over an oblong sheet iron shovel, with a flat bottom, and with raised edges on its sides, which is held in a slanting direction over the melting pot. As many of these sheets are then loosely rolled up as may be sufficient to form a cylinder five or six inches in diameter, and seven or eight high, which is placed in an earthen pot containing about half a pint of vinegar, and having within a few inches from the bottom three equidistant projecting knobs in the earthenware, on which the cylinder of lead is supported in order to keep it from contact with the vinegar. The pots thus prepared are placed side by side, in horizontal layers, in a building roughly constructed of boards, with interstices between them. The first layer is covered with boards,

on which a stratum of tan or of refuse straw from the stables is strewed, and fresh layers of pots, boards, and tan or straw are successively placed until the building is filled. The sides are also enclosed with straw. The layers of pots contained in one building, called a stack, are allowed to remain undisturbed for about six weeks, at the end of which time they are unpacked, and the cylinder of sheet lead in each pot, though still retaining its shape, is found almost entirely converted into a flaky, white, friable substance, which is the white lead. This is separated from the lead yet remaining in the metallic state, ground in water, whereby it is washed and reduced to fine powder, and finally dried in long shallow reservoirs, heated by steam. Pelouze has succeeded in explaining these processes on one general principle. In Thénard's process it is admitted that the same portion of lead acetate unites with oxide, and gives it up again to carbon dioxide to form the carbonate. In the modified English process, referred to above, he supposes that the one per cent. of lead acetate combines with sufficient litharge to convert it into subacetate, which immediately returns to the state of neutral acetate by yielding up its excess of base to form the carbonate with the carbon dioxide. The acetate is now ready to combine with a fresh portion of litharge, to be transferred to the carbon dioxide as before, and thus the small proportion of acetate, by combining with successive portions of the litharge, finally causes the whole of the latter to unite with the carbon dioxide. In the Dutch process, Pelouze has rendered it almost certain that none of the oxygen or carbon dioxide of the carbonate is derived from the vinegar. In this process he supposed that the heat generated by the fermentation of the tan or straw volatilizes the vinegar, the acetic acid of which, with the assistance of the oxygen of the air, forms with the lead a small portion of subacetate. This, by reacting with the carbon dioxide resulting from the decomposition of the tan or straw, or derived from the atmosphere, forms lead carbonate, and is brought to the state of neutral acetate. The neutral acetate returns again to the state of subacetate, and, by alternately combining with and yielding up the oxide, causes the whole of the lead to be finally converted into carbonate.

The temperature of the stacks of pots in the Dutch process is about 45° C. (113° F.). If it falls below 35° C. (95° F.), a part of the lead escapes corrosion, and if it rises above 50° C. (122° F.), the product is yellow. The form of acetic acid usually employed in this process is vinegar, but the variable nature of that liquid as to strength and purity is an objection to its use, and, accordingly, other forms of the acid have been substituted with advantage, as, for example, the purified acetic acid from wood in a diluted state. The German or chamber process differs from the Dutch process only in that the vessels containing the lead are placed in chambers having a perforated floor, through the

openings of which the fumes of acetic acid rise, acting upon the lead, while carbon dioxide from the burning of coke is passed in and through the chamber. This process is cheaper than the Dutch method, and is said to give an equally satisfactory product. Another method, which yields a white lead of excellent covering power, is the process patented in England by Dale and Milner. This consists in carefully grinding between millstones a mixture of litharge or any insoluble basic lead salt with water and sodium bicarbonate. Milner has improved upon this method by grinding a mixture of 4 parts of finely divided litharge with 1 part of common salt and 16 parts of water. After about 4½ hours the reaction is complete. The mixture of basic lead chloride and caustic soda is then transferred to a leaden vessel, well stirred with a wooden pestle, and a current of carbon dioxide passed through it until the liquid is neutral. If the carbon dioxide be passed in too long, the product will be spoiled. (*Roscoe and Schorlemmer*, vol. ii. 1, 293.) In Carter's process, used in this country extensively, granulated metallic lead is moistened with acetic acid and submitted to the action of carbon dioxide gas in revolving barrels. The production of white lead in the United States reaches large proportions, amounting in 1904 to 123,346 short tons, valued at \$13,756,929.

Properties.—According to the U. S. P. 1890, lead carbonate is "a heavy, white, opaque powder, or a pulverulent mass, without odor or taste. Permanent in the air. Insoluble in water or alcohol, but soluble in acetic or diluted nitric acid, with effervescence. When strongly heated, the salt turns yellow without charring, and, if heated in contact with charcoal, it is reduced to metallic lead. If 2 Gm. of the salt be dissolved in a mixture of 2 Cc. of nitric acid and 10 Cc. of water, it should not leave more than 0.02 Gm. of residue (limit of *insoluble foreign salts*). This solution yields a black precipitate with hydrogen sulphide test-solution, a yellow one with potassium iodide test-solution, and a white one with diluted sulphuric acid. On completely precipitating the solution with hydrogen sulphide, the filtrate should not leave more than a trifling residue on evaporation (limit of *salts of the alkalis, alkaline earths, or of zinc*). If 1 Gm. of the salt be strongly ignited, in a porcelain crucible, it should leave a residue of lead oxide weighing not less than 0.85 Gm." U. S. 1890. It is sometimes adulterated with barium, calcium, and lead sulphates, particularly the first. A mixture of equal parts of white lead and barium sulphate is known as *Venetian white*, while *Hamburg white* is a mixture of 1 part of white lead and 2 parts of barium sulphate, and *Dutch white* of 1 part to 3 of barium sulphate. Louyet has examined samples of French white lead containing considerably more than half their weight of barium sulphate. These sulphates, if present, are left undissolved by nitric acid. Chalk or whiting is another adulteration. This

may be detected by adding to the nitric solution of the white lead an excess of potassium hydroxide, which will redissolve the lead monoxide first thrown down, but leave a white powder of lime. The Br. Pharm. describes it as a soft, heavy powder, insoluble in water, entirely soluble in diluted acetic acid. Neutral lead carbonate consists of one atom of lead, one of carbon, and three of oxygen. Commercial white lead is a compound of lead carbonate and hydroxide. Its formula is generally taken as $2\text{PbCO}_3 + \text{Pb(OH)}_2$. According to Stein, white lead, when submitted to simple calcination, loses 14.5 per cent. of its weight, and a mode of determining its purity is thus afforded. (*J. P. C.*, Jan. 1859, 78.) But the fact seems to be, from the observations of Wm. Baker, that the commercial white lead contains variable proportions of the hydrated oxide, from a mere trace to the amount of 1 molecule to 3 molecules of the neutral carbonate. (*Chem. News*, Aug. 10, 1861, 74.)

Uses.—White lead is ranked in the *Materia Medica* as an astringent and sedative. It is employed externally only, being used, in the form of ointment, as an application to *ulcers* and to *inflamed and excoriated surfaces*. It was recommended in *scalds and burns* by Gross, and Alfred Freer has found it very useful in *erysipelas, eczema, carbuncle*, etc. (*P. J.*, Aug. 1859.) The white lead is first brought to the consistence of cream by linseed oil, as in making common white paint, and then brushed over the inflamed surface. Its free continued external use has produced lead poisoning. (*Case*, *N. A. Medico-Chir. Rev.*, July, 1857, p. 605.) Although highly insoluble, on account of its frequent use in the arts and of the ease of its formation when lead is exposed to chemical influences, lead carbonate probably produces chronic poisoning more often than any other preparation of the metal. The constant use of face powders and cosmetics containing lead carbonate, or "*flake white*," as it is sometimes called, has produced serious results.

PLUMBI IODIDUM. U. S., Br.

LEAD IODIDE

(plūm'bi i-ōd'ī-dūm)

$\text{PbI}_2 = 457.15$

"It should contain not less than 99 percent. of pure Lead Iodide, and should be kept in well-stoppered bottles, protected from light." *U. S.* "Precipitated Lead Iodide, PbI_2 , is obtained by the interaction of lead nitrate or acetate and potassium iodide." *Br.*

Plumbum Iodatum, Ioduretum Plumbicum, Iodure de Plomb, *Fr. Cod.*; Jodblei, *G.*; Yoduro plumbico, *Sp.*

"Take of Nitrate of Lead, Iodide of Potassium, each, *four ounces* [avoirdupois]; Distilled Water a *sufficiency*. Dissolve the Nitrate of

Lead, by the aid of heat, in a pint and a half, and the Iodide of Potassium in half a pint of the Water, and mix the solutions. Collect the precipitate on a filter, wash it with Distilled Water, and dry it in a warm place." *Br.* 1885.

No process is given in the U. S. P. (8th Rev.) nor Br. Ph. 1898 for Lead Iodide. The process of the U. S. P. 1870 was identical with that of the British Pharm. 1885 given above.

The lead nitrate gives up its metal to the iodine, receiving the potassium, the operation taking place between one molecule of the lead nitrate and two molecules of the potassium iodide. The potassium nitrate thus formed remains in solution, while the lead iodide is precipitated,

The theoretical quantities of lead nitrate and potassium iodide are 328.49 of the former and 329.52 of the latter, or almost precisely equal quantities. The proportions should be as nearly as possible those of exact saturation. An excess of the potassium iodide, independently of the waste, has the disadvantage of holding a portion of the lead iodide in solution, while, according to Christison, an excess of lead over the iodine disposes to the formation of the lemon-yellow insoluble lead oxyiodide. By the use of equal quantities of the two salts these disadvantages are avoided. As lead iodide is slightly soluble in cold water, it is desirable to use as little of the solvent as will answer, and hence the comparatively small proportion of water employed.

In the former London process lead acetate was employed instead of the nitrate, but De-paire of Brussels, ascertained that in this process a considerable amount of iodide remains in solution after the precipitation of the lead iodide, and F. Boudet states that the quantity of the iodide resulting from the process is 10 per cent. less than theory would indicate. By the addition of nitric acid to the solution, after precipitation, an additional quantity of lead iodide is obtained. Boudet ascribes this result to the formation of a portion of soluble potassium and lead iodide, whenever lead iodide and potassium acetate are in contact. By substituting lead nitrate for acetate, he found that a quantity of lead iodide was obtained as near that required by theory as the solubility of the lead iodide permits. (*J. P. C.*, 3e sér., xi. 274.) The official process is on the whole to be preferred to that in which lead acetate is used, and especially as the nitrate is more easily obtained pure. Some interesting experiments have been made by T. Huraut of Paris, on the different methods of preparing lead iodide. It may be obtained by the reaction between any of the soluble iodides and the soluble lead salts. It resulted from his observations that of the two lead salts employed, the nitrate was to be preferred, and of the various iodides, though potassium iodide yielded a very handsome product, yet calcium iodide afforded one not inferior in quality, and somewhat greater in quantity.

Upon a small scale, as the process is performed by the apothecary, the difference would be of little consequence, but it might be important to the manufacturer. (See *A. J. P.*, xxi.)

Properties.—As officially described, it is in the form of “a heavy, bright yellow powder, without odor or taste; permanent in the air. Soluble in about 1300 parts of water at 25° C. (77° F.), and in about 200 parts of boiling water, separating from the latter solution on cooling in brilliant, golden-yellow crystalline laminae; very slightly soluble in alcohol, but soluble, without color, in solutions of the fixed alkalies, in concentrated solutions of the alkali acetates, of potassium iodide, and of sodium thiosulphate, and in a hot solution of ammonium chloride. When moderately heated, the salt fuses to a thick, reddish-brown liquid, which congeals, on cooling, to a yellow, crystalline mass. At a higher temperature it is decomposed, with the evolution of violet vapors of iodine, leaving a lemon-yellow residue of lead oxyiodide. If 1 Gm. of the salt be triturated with 2 Gm. of ammonium chloride and 2 Cc. of water, a nearly white mixture will result. If this be transferred to a test-tube, and heated in a water-bath for a few minutes, a clear and almost colorless solution should be formed (absence of *chromate* and *other insoluble foreign salts*). On cooling this solution, a solid mass of nearly colorless, fine, silky crystals will be produced, and on adding water or diluted sulphuric acid to this mass, yellow Lead Iodide will separate. Add 0.1 Gm. of the salt to 5 Cc. of water, and heat the mixture until it boils; cool the liquid and filter it into a test-tube of about 40 Cc. capacity, then add 5 Cc. of potassium hydroxide T.S. and about 0.2 Gm. of aluminum wire, insert in the upper portion of the test-tube a pledget of purified cotton, and over the mouth, place a piece of moistened red litmus paper; then if the tube be heated on a water-bath for fifteen minutes, no blue coloration of the paper should be discernible (limit of *nitrate*). If 1 Gm. of Lead Iodide be boiled for a few minutes with 20 Cc. of water, the mixture then cooled and filtered, and the lead removed from the filtrate by hydrogen sulphide, a portion of the second filtrate, after boiling to drive off hydrogen sulphide and carefully neutralizing with ammonia water, should not be colored red by a drop of ferric chloride T.S. (absence of *acetate*). Another portion of this filtrate, if evaporated to dryness, should leave no residue (absence of *soluble foreign salts*).” *U. S.* “A heavy bright-yellow powder, soluble in about 2000 parts of cold and in about 200 parts of boiling water, and deposited in golden-yellow crystalline scales as the latter solution cools; entirely soluble in *solution of ammonium chloride*. It affords the reactions characteristic of lead and of iodides. It should yield no characteristic reaction with the tests for nitrates or acetates.” *Br.* According to Soubeiran, it is soluble in 1235 parts of cold water, and 194 of boiling water, which, on cooling, deposits it

in minute, shining, golden-yellow, crystalline scales. It is freely soluble in a concentrated solution of sodium acetate (Donato Tommasi, *P. J.*, 3d series, ii. 805). It should be kept excluded from the light. It is stated by Engelhardt that iodine is separated from lead iodide by ferric and cupric chlorides, while the other metallic chlorides have no such effect, producing compounds of iodides of the metal employed with lead chlorides.

Uses.—This compound is supposed to have the resolvent properties of iodine, combined with those which are peculiar to lead, and was at one time recommended in *tuberculous diseases*, in which, however, it has proved wholly inefficient. It is said to have been usefully employed in the discussion of *scrofulous tumors* and other indolent swellings, and in the cure of obstinate *ulcers*, and for these purposes has been used both internally and locally in the form of an ointment. According to Cogswell, if given for some time in small doses, it produces the effects of lead, but not those of iodine, upon the system. (*Christison's Dispensatory*.)

Dose, half a grain to four grains (0.032 to 0.26 Gm.).

PLUMBI NITRAS. U. S.

LEAD NITRATE

(plūm'bī nī'trās)

$\text{Pb}(\text{NO}_3)_2 = 328.49$

“It should contain not less than 99.5 percent. of pure Lead Nitrate $[(\text{NO}_2\text{O})_2\text{Pb}]$, and should be kept in well-closed vessels.” *U. S.*

Nitrate of Lead; Plumbum Nitricum, Nitrates (Azotates) Plumbeus; Azotate de Plomb, Nitrate de Plomb, *Fr. Cod.*; Salpetersaures Bleioxyd, Bleisalpeter, *G.*; Nitrato di piombo, *It.*; Nitrato plumbeo, Nitrato de plomo, *Sp.*

Neither the *U. S.* nor the *Br. Pharmacopœia* gives a formula for the preparation of this salt. It may be readily prepared by the process of the old Dublin Pharmacopœia: “Take of Litharge, in fine powder, *five ounces* [avoirdupois]; Pure Nitric Acid *two fluidounces*; Distilled Water *three pints* [Imp. meas.]; Dilute Nitric Acid *a sufficient quantity*. To the Litharge, placed in a porcelain dish, add the Acid with a pint and a half of the Water, and, applying a sand heat, and occasionally stirring the mixture, evaporate the whole to dryness. Upon the residue boil the remainder of the Water, clear the solution by filtration, and, having acidulated it by the addition of a few drops of the Dilute Nitric Acid, evaporate until a pellicle begins to form. The heat being now withdrawn, crystals will form on the cooling of the solution, which should be dried on blotting-paper in a warm atmosphere, and preserved in a close bottle.”

In this process the nitric acid unites directly with the lead oxide to form the nitrate.

Properties.—This nitrate is officially described as in "colorless, transparent, octahedral crystals, when obtained by the spontaneous evaporation of cold solutions, or white, nearly opaque crystals, when formed by the cooling of hot solutions; without odor, and having a sweetish, astringent, afterwards metallic, taste; permanent in the air. Soluble in 1.85 parts of water at 25° C. (77° F.), and in 0.75 part of boiling water; almost insoluble in alcohol. When strongly heated, the salt decrepitates, emits nitrous vapors, and finally leaves a residue of lead oxide. The aqueous solution of the salt has an acid reaction upon blue litmus paper, and yields a black precipitate with hydrogen sulphide T.S., a yellow one with potassium iodide T.S., and a white one with diluted sulphuric acid. The aqueous solution of the salt (1 in 10) should give, with potassium ferrocyanide T.S., a pure white precipitate (absence of copper and iron). If hydrochloric acid be added to the aqueous solution of the salt until no further precipitate is produced, and the remainder of the lead be removed from the filtrate by hydrogen sulphide, a portion of the second filtrate should not be affected by the addition of a slight excess of ammonia water (absence of zinc and iron). Another portion of this filtrate, when evaporated to dryness, should not leave a weighable residue (limit of salts of the alkalies and those of magnesium, calcium, zinc, and iron)." U. S. It is composed of one atom of lead, combined with two nitric acid groups, (NO₃)₂, without water of crystallization. This salt is largely used in dyeing and calico printing, for the preparation of mordants, and of chrome yellow.

Uses.—The effects of this salt upon the system are the same as those of the other soluble lead salts, but, though formerly employed, it is now quite out of use as an internal remedy. Externally it is occasionally applied to excoriated surfaces, and a solution made in the proportion of ten grains to an ounce of water, and colored probably with alkanet, has been used on the continent of Europe as a secret remedy in *sore nipples, chapped hands, cracked lips*, etc., and it undoubtedly, in solutions whose strength should be adapted to the individual case, is a valuable local remedy in diseases of the skin and mucous membrane, such as *leucorrhæa, gonorrhæa, ulcers*, and *chronic impetiginous affections*. It may be used to correct fetid odors dependent on the presence of hydrogen sulphide or ammonium sulphhydrate, which it decomposes, but it is not a germicide or true disinfectant. *Ledoyen's disinfecting fluid* is a solution of lead nitrate in the proportion of a drachm to an ounce. Should the salt be used internally, the dose would be from one-fourth to one-half of a grain (0.016 to 0.032 Gm.). Moerlonge and Vanzette ascribe remarkable efficiency to lead nitrate in *onychia maligna*, and their statements have been confirmed by other practitioners. It is applied by sprinkling the pow-

der on the surface, and, according to J. Scott of Belfast, Ireland, a complete cure may be relied on in from fourteen to thirty days. (*Dublin Q. J.*, Feb. 1874, p. 145.)

Dose, one-fourth to one-half grain (0.016 to 0.032 Gm.).

PLUMBI OXIDUM. U. S., Br.

LEAD OXIDE [Litharge]

(plūm'bī ōx'ī-dūm)

PbO = 221.23

"It should contain not less than 96 percent. of pure Lead Oxide, and should be kept in well-closed vessels." U. S. "Lead Oxide, PbO, is prepared by the action of air on melted lead." Br.

Oxide of Lead; Lithargyrum, Plumbum Oxydatum, Plumbi Oxidum Semivitreum; Oxide (proto) de Plomb fondu, Litharge, *Fr. Cod.*; Protoxide de Plomb, *Fr.*; Bleiglätte, Bleioxyd, *G.*; Litargirio, *It.*, *Sp.*

When lead oxide is rendered semi-crystalline by incomplete fusion it becomes the *semi-vitrified oxide*, or litharge. Almost all the litharge of commerce is obtained, as a secondary product, in the process for extracting silver from argentiferous galenas. After extracting the argentiferous lead from the ore, the alloy is placed upon an oval slightly concave dish, about three feet long and twenty inches wide, called a *test*, made by beating pulverized bone ash, formed into a paste with water, into a mould, the sides of which consist of an elliptical band of iron, and the bottom of strips of sheet iron, placed at short distances apart. The test is of such a size as exactly to fit an opening in the floor of a reverberatory furnace, where it is placed and adjusted to the level of the floor. On one side of the test the fireplace is situated, and exactly opposite, the chimney, while at one extremity of it the pipe of a strong bellows is placed, and at the other a vertical hole is made, communicating with a gutter leading from the test. The furnace is now lighted, and shortly afterwards the bellows are put in motion. The lead fuses and combines with oxygen, and the resulting oxide, melting also, forms a stratum which floats on the surface, and which is driven by the blast of the bellows along the gutter and through the vertical hole into a receiver below, where, upon solidifying, it crystallizes in small scales, which form the litharge. In proportion as the lead is oxidized and blown off the test, fresh portions are added so as to keep it always sufficiently full. The process is continued for eight or ten days, after which no more lead is added. The operation is now confined to the metal remaining on the test, and, the oxidation proceeding, a period at last arrives when the whole of the lead has been blown off as litharge, and the silver, known to be pure by its brilliant appearance in the fused state, alone remains. This is then removed, and the pro-

cess repeated on a fresh portion of argentiferous lead. The yellow amorphous lead oxide as a paint color is known as *massicot*, and is prepared by careful heating of lead carbonate or nitrate to a point short of the fusion of the resulting oxide.

Properties.—It is officially described as “a heavy, yellowish or reddish-yellow powder or minute scales, without odor or taste. On exposure to the air it slowly absorbs moisture and carbon dioxide. Almost insoluble in water, to which it, however, imparts a faintly alkaline reaction; insoluble in alcohol, but soluble in acetic or diluted nitric acid, and in warm solutions of the fixed alkali hydroxides. When heated, the Oxide assumes a brownish-red color, becoming yellow again on cooling; it fuses at a red heat. When heated in contact with charcoal, it is reduced to metallic lead. Lead Oxide should be soluble in diluted nitric acid, with but little effervescence (limit of *carbonate*), and without the development of the odor of nitrous acid (absence of *lead*), leaving not more than a trifling residue (limit of *silicates*, *barium sulphate*, etc.). The solution in diluted nitric acid, which should be colorless, when nearly neutralized by ammonia water yields with hydrogen sulphide T.S. a black precipitate, with potassium iodide T.S. a yellow one, and with diluted sulphuric acid a white precipitate, the latter two being soluble in a strong solution of sodium hydroxide. If from the solution in diluted nitric acid the lead be precipitated by sulphuric acid, the filtrate, after the addition of an excess of ammonia water, should not assume more than a slight bluish tint (limit of *copper*), nor yield more than traces of a reddish-brown precipitate (limit of *iron*). If 5 Gm. of the Oxide contained in a small flask be shaken with 5 Cc. of water, then 20 Cc. of acetic acid added, and the mixture boiled for a few minutes and filtered, the insoluble residue, when well washed and dried, should not weigh more than 0.2 Gm. (absence of more than 4 percent. of *insoluble impurities*). If, to the mixed filtrate and washings obtained in the last test, hydrochloric acid be added until no further precipitate be produced, the remainder of the lead removed from the filtrate by hydrogen sulphide, and the liquid filtered, the second filtrate, upon evaporation to dryness, should not yield a residue weighing more than 0.050 Gm. (limit of *soluble impurities*). When strongly heated in a porcelain crucible, the Oxide should not lose more than 4 percent. of its weight (limit of *carbonate* and of *moisture*).” *U. S.* “Heavy scales of a pale yellowish-red color, completely soluble in *diluted nitric acid* and in *acetic acid*. It gives the reactions of lead, but should yield no characteristic reaction with the tests for copper, iron, or carbonates.” *Br.* It slowly attracts carbon dioxide from the air, and contains more of this acid the longer it has been exposed. It is on this account that it commonly effervesces slightly with the diluted acids. It has the property of decolorizing wines, when

agitated with them. When heated with the fats and oils, in connection with water, it saponifies them. (See *Emplastrum Plumbi*.) Heated with charcoal, it is reduced to the metallic state. In diluted nitric acid it should be almost entirely soluble; and the solution is affected by potassium hydroxide in the same manner as that of the carbonate. (See *Plumbi Carbonas*.) As it occurs in commerce, it usually contains iron, copper, and a little silver and silica. It may be purified from iron and copper by digestion in diluted sulphuric acid. The English litharge is most esteemed, that from Germany being generally contaminated with iron and copper. In choosing litharge, samples should be selected which are free from copper and from fragments of vegetable matter. Copper is detected if upon adding potassium ferrocyanide to a nitric acid solution of the litharge a brown instead of a white precipitate is produced. Two varieties of litharge are distinguished in commerce, named from their color, and dependent on differences in the process employed. Sometimes it has a pale yellow color and silvery appearance, and is then denominated *silver litharge* or *yellow litharge*; at other times it is of a red color, and is known under the name of *gold litharge* or *red litharge*. The latter was supposed to owe its color to the presence of a portion of red lead, but Leblanc has shown that the two varieties of litharge differ in color, structure, and density only, and not in chemical composition. In this respect litharge is essentially identical with lead oxide. (See *Plumbum*.) The carbon dioxide which it contains is variable, but its average amount is about 4 per cent. Lead peroxide and red lead in litharge may be detected by heating it in a test tube with sodium chloride and potassium bisulphate and introducing a slip of paper colored blue by indigo. If either of these oxides be present, the paper will be bleached by the chlorine evolved.

Uses.—Litharge is never used internally, but is employed in several pharmaceutical operations, and forms an ingredient in various external applications, used for abating inflammation, and for other purposes. In the arts it is employed in the glazing of pottery, in painting to render oils drying, and as an ingredient in flint glass.

PLUMBUM.

LEAD

(plūm'būm)

Pb = 205.35

Plomb, *Fr.*; Blei, *G.*; Lood, *Dutch*; Piombo, *It.*; Plomo, *Sp.*

Lead is not official in its metallic state, but enters into a number of important medicinal preparations. It occurs in nature as an oxide,

as a sulphide called *galena*, and in saline combinations, forming the native lead sulphate, phosphate, carbonate, chromate, molybdate, tungstate, and arsenate. The oxide is rare, but galena is exceedingly abundant, and is the ore from which nearly all the lead of commerce is extracted. The extraction is effected either by melting the ore in contact with charcoal, or, in the case of pure galenas, by what is termed the *air reduction* process. In this case the galena is first roasted, when it is in part changed into oxide, PbO , and sulphate, $PbSO_4$. The doors of the furnace are then closed, and the unchanged sulphide reacts with both the oxide and the sulphate as follows:

whereby all the lead is obtained in the metallic state. Lead is also successfully obtained by electrolysis directly from the galena. This is reduced at the cathode of an electrolytic cell, while hydrogen sulphide is formed at the same time and may be collected or burned to form sulphur dioxide, which is then utilized. The process is now in operation at Niagara Falls. The richest and most extensive mines of galena are found in this country. The non-argenticiferous lead region of the United States extends in length from Wisconsin in the north to the Red River of Arkansas in the south, and in breadth about one hundred and fifty miles, being chiefly in the State of Missouri, while Utah, Idaho, Montana, and Colorado furnish argenticiferous galena. The production of lead in the United States for the year 1903 was 352,848 tons, of which 292,874 tons were from domestic ores; in 1904, 344,755 tons of which 318,679 tons were from domestic ores. Over two-thirds from domestic ores was desilverized, and the remainder non-argenticiferous.

Properties.—Lead is a soft, bluish-gray, and very malleable metal, presenting a bright surface when newly melted or cut. It has a perceptible taste, and a peculiar odor when rubbed. It undergoes but little change in the air, but is acted on by the combined influence of air and rain water, which gives rise to a hydrate, which is afterwards changed, in part, into carbonate, by absorbing carbon dioxide from the atmosphere, and if in water, the carbonate is imparted to it in the state of bicarbonate, which dissolves and renders the liquid poisonous. This chemical effect on the metal is greater in proportion as the water is purer. Aqueous vapor passed through leaden pipes has a similar corroding effect, which is greater as the lead is purer. (*A. J. P.*, 1863, p. 507.) Spring and river water act on lead differently, the lead becoming slowly oxidized, and covering itself with a black coating of suboxide, which adheres strongly to the metal, and thus in some measure protects the water. (Langlois, *J. P. C.*, 4e sér., ii. 29.) Stalman has satisfied himself, by experiment, that an extremely minute quantity of ammonia or of nitric acid will very much promote the action of water

upon lead,—a millionth of ammonia being sufficient for the purpose. (*Ibid.*, iv. 467.) Metallic lead seems to be liable to the attacks of certain insects, which bore into and sometimes through it, not using it as food, but apparently in search of secure places of retreat for future development. A knowledge of this fact may sometimes be important. (*A. J. P.*, Jan. 1865, p. 72.) Its sp. gr. is 11.4, melting point $334^\circ C.$ ($633.2^\circ F.$), and atomic weight 205.35. Exposed to a stream of oxygen on ignited charcoal, it burns with a blue flame throwing off dense yellow fumes. The best solvent of lead is nitric acid, but the presence of sulphuric acid destroys, and that of hydrochloric acid lessens, its solvent power, on account of the insolubility of the lead sulphate and chloride. Lead forms a suboxide, Pb_2O , a monoxide, PbO , a sesquioxide, Pb_2O_3 , a dioxide, PbO_2 , and a compound of the monoxide and the dioxide, which has a varying composition, but is usually Pb_3O_4 . The *monoxide*, called in commerce *massicot*, or *litharge*, may be obtained by calcining, in a platinum crucible, lead subnitrate, formed by precipitating a solution of the nitrate by ammonia.

On a large scale it is made by exposing melted lead to the action of the air. Its surface becomes encrusted with a gray pellicle, which, being scraped off, is quickly succeeded by another; and the whole of the metal, being in this way successively presented to the air, becomes converted into a greenish-gray powder, consisting of monoxide and metallic lead. This, on exposure to a moderate heat, absorbs more oxygen, and is converted wholly into monoxide. This oxide has a yellowish color, and is the only oxide capable of forming salts with the acids. It consists of one atom of lead and one of oxygen. *Litharge* is very much used in pharmacy, and is official in all the Pharmacopœias. (See *Plumbi Oxidum*.) The *sesquioxide*, discovered by Winckelblech, is unimportant. The *dioxide*, called also *puce oxide*, from its flea-brown color, may be obtained by treating red lead with nitric acid. The acid takes up the monoxide and leaves the dioxide, which may be purified by washing with boiling water. A more productive process is to precipitate four parts of lead acetate by three of sodium carbonate, and then to pass into the thin pasty mass of lead carbonate a stream of chlorine, which converts the monoxide of the carbonate into the brown dioxide. (F. Wöhler.) Solution of chlorinated soda may be conveniently employed to furnish the necessary chlorine. Lead dioxide is a tasteless powder, of a dark brown color. When heated to redness it loses half its oxygen and becomes monoxide. It consists of one atom of lead and two atoms of oxygen. The *red oxide*, Pb_3O_4 , called in commerce *minium*, or *red lead*, is described under another head. (See *Plumbi Oxidum Rubrum*.) Lead combines with iodine, forming the official lead iodide. The acetate and nitrate are also official.

The best tests of lead are hydrogen sulphide and a solution of potassium iodide. The former produces a black precipitate of lead sulphide, the latter a yellow one of lead iodide.

Uses.—In concentrated form and sufficient amount the soluble preparations of lead are violent irritant poisons, producing burning in the œsophagus and stomach, soon involving the whole abdominal cavity, followed by vomiting and sometimes by purging, or more rarely by constipation. The insoluble preparations of lead are incapable of acting as acute irritant poisons, but are the common causes of subacute and chronic lead poisoning. The subacute form of the poisoning, the so-called *colica pictorum*, is very common among painters, makers of white lead, and other artisans who work in the metal. It is, however, also frequently seen in other persons, into whom the lead finds entrance in almost innumerable ways, especially with drinking water and food. *Colica pictorum* usually begins with dyspeptic symptoms and obstinate constipation, associated with violent pain of a twisting character, which seems to centre round the umbilicus; the abdominal walls are spasmodically retracted, and there is even early malaise, lassitude, depression of spirits, and failure of the general health. The stools are whitish and scanty. A characteristic symptom is a blue line situated upon the margin of the gums where they join the teeth, due to the deposit of the lead sulphide. This blue line is usually present in all forms of subacute and chronic lead poisoning, and is pathognomonic. It may, however, be absent even in the most severe cases.

The symptoms of chronic lead poisoning may conform to the regular type or may be most bizarre. They are frequently, but not always, preceded by *colica pictorum*. The most characteristic phenomenon is the double wrist-drop, which is due to a paralysis of the extensors of the forearm, and is associated with wasting and degenerative changes in the diseased muscles. If these symptoms progress, failure of strength and anæmia gradually develop, the extensors of the leg become affected, irregular, localized, or wide-spread tracts of anæsthesia appear, and neuralgic pains occur in various parts of the body; little by little the whole muscular system becomes involved, emaciation progresses, anæmia becomes extreme, and death in a condition of cachexia ensues. Albuminuria is not a rare symptom of chronic lead poisoning; it may be due simply to the momentary irritation of the kidney, or may be the result of degenerative changes which end in complete destruction of the secreting structure, with final contraction of the organ. As the result either of primary changes in the renal organs or of a direct action of the lead upon the cerebral tissue, epileptic convulsions may occur at long intervals, or they may be associated with delirium, coma, or other evidences

of cerebral disturbance. When these attacks are secondary to kidney disease they are uræmic; in saturnine cerebritis, furious convulsions, coma, and wild delirium may come on suddenly, and may prove fatal in a very few hours.

Another irregular form of lead poisoning is that in which the symptoms exactly resemble those of gout; swelling of the joints, with pain, excessive tenderness, and even secondary degeneration of the arteries, similar to that which occurs in chronic gout, may make the likeness complete. Saturnine amaurosis, due to atrophy of the optic nerve, is a rare form of plumbism. A variety of lead poisoning rarely spoken of in books, of which H. C. Wood has seen a number of instances, is that in which the symptoms closely resemble those of acute poliomyelitis; wide-spread paralysis scattered in different groups of muscles, with wasting and change in the electrical reactions of the affected parts, may very closely simulate the ordinary form of spinal disease, but almost invariably the true nature of the attack may be recognized by noticing that the bladder and the rectum are affected, and not rarely the occurrence of violent neuralgic pain points still more definitely to a saturnine origin.

The symptoms of lead poisoning may also take the form of simple progressive anæmia, with failure of health and obscure nervous phenomena, such as apparently causeless neuralgic pains, wide-spread formications, insomnia, etc. The diagnosis of the true nature of an attack of lead poisoning is of the utmost importance. In most cases it is to be readily made by noticing the blue line on the gums. When this is absent it is essential that the urine be examined chemically for lead.¹ As the

¹ The most delicate method of testing urine for lead is that devised by Lehmann as modified by John Marshall. Concentrated hydrochloric acid is added to the urine in the proportion of 10 Cc. to 100 Cc. To the boiling mixture are added from time to time small portions (0.2 Gm.) of potassium chlorate until the liquid is of a pale straw-color and the odor of chlorine strongly perceptible. The heating is then continued without further addition of potassium chlorate until the chlorine odor disappears. On cooling the liquid is filtered and the filtrate diluted with water until its volume equals the original volume employed. The filtrate is then placed in a glass tube of about 3.5 Cm. diameter, the end of the tube being covered with parchment paper fastened with twine. (A new piece of parchment paper should be used in each analysis, and care be taken to see that it and the twine as well as the other reagents used are free from lead.) A glass tripod on which there is a piece of platinum foil about 2.5 Cm. square attached to a platinum wire is placed in a glass vessel containing distilled water very slightly acidulated with chemically pure sulphuric acid, the liquid covering the platinum foil. The parchment tube containing the urine to be examined is then set on the foil on the tripod, the parchment covered end being placed directly over the foil. Another piece of platinum foil, purposely cut round so as nearly to equal the calibre of the parchment covered tube, attached at the centre to a wire (which wire, for the purpose of insulation, passes through a glass tube about twenty-five centimeters in length, and sealed at both ends), is put into the urine, so that the platinum foil in the tube, serving as a negative pole, should lie on the parchment paper as nearly as possible over the positive platinum pole, which is under the parchment paper on the glass tripod. The wires are connected with a battery consisting of three Grove cells. The cur-

elimination takes place irregularly and is much favored by the internal administration of potassium iodide, that salt should always be given for a few days before the examination of the urine.
